We have used successfully electrodes of this type with conventional flat microelectrophoresis cells over a period of a year in studies on erythrocytes and bacteria. Current densities in excess of 10 m.amp./cm.^{2} of electrode area could ordinarily be used without gas evolution. Thus quite small electrodes are suitable even for studies at high ionic strengths.

In Fig. 1,*b*, the palladium tube serves as a bielectrode separating the solution leading to the electrophoresis cell and the solution surrounding the primary electrode (for example, Ag/AgCl). Here gas evolution resulting from exhaustion or saturation of atomic hydrogen at the electrodes would not occur regardless of the duration of the current since equivalent amounts of hydrogen are released and taken up by opposite faces of each bielectrode. The choice of the half-cell to be used inside the palladium anode tube should be made with care since the presence of soluble oxidants such as oxygen would result in the consumption of atomic hydrogen present on the palladium surface before it could enter the bulk of the metal. Hence the supply of hydrogen in the metal would eventually be depleted and gas bubbles might form at the exterior surface of the tube.

In the cell of Fig. 1,*c*, the interior of the palladium tube anode is continuously flushed with hydrogen gas and the cathode is open to the air. On passage of current through the system the hydrogen dissolved in the anode from the gas phase migrates through the wall of the palladium tube and reacts at the solution interface as indicated in the equations given above. At the cathode, atomic hydrogen derived from the reduction of hydronium ions in the solution migrates through the wall of the tube and reacts with atmospheric oxygen to form water. With these electrodes, current could obviously be passed in one direction indefinitely with no danger of gas formation at either electrode. This system would not be convenient, however, where frequent reversal in current direction is necessary (as in microelectrophoresis) since the hydrogen and air connexions would have to be exchanged with each reversal. Electrodes of this type have been used successfully in an electrochemical cell[6].

A few precautions in the use of palladium electrodes are worth mentioning. A palladium anode immersed in a halide solution will react to give a soluble palladium halide salt if its store of hydrogen is exhausted. Charging a palladium electrode beyond a hydrogen/palladium ratio of about 0·6 will lead to an increase in volume of about 10 per cent[7]. Repeated cycles of charging beyond this ratio followed by complete discharge may cause the metal to crack. By restricting the maximum amount of hydrogen dissolved to a ratio of about 0·5 the electrodes may be expected to have an indefinite life.

Separation of Uranium by Reversed Phase-Partition Chromatography

IN almost all analytical methods for the determination of uranium, it is necessary first to separate the uranium from other substances.

A convenient and selective method of achieving this separation is to extract the uranium from a nitric acid solution into a solution of tributyl phosphate in kerosene, the latter serving to facilitate separation of the two phases. Usually two extractions are required, one to transfer uranium to the organic phase and one to return it to an aqueous phase for determination.

The use of tributyl phosphate on a partition chromatographic column would reduce the hazard of manipulating radioactive material, improve the partition of uranium into the organic phase, and have the effect of a large number of manual solvent extractions. Such a column has been successfully used in these laboratories for the past eleven months (internal publication and patent application).

The stationary phase is prepared from purified tributyl phosphate. A mixture of 100 ml. of commercial tributyl phosphate and 150 ml. of 0·5 *M* sodium hydroxide is steam distilled until no odour of butyl alcohol is present in the distillate. After cooling, the residual tributyl phosphate is separated from the alkali and washed with 100 ml. of distilled water, followed by three 50-ml. portions of 3 *M* nitric acid. For the solid support, 'Low density, *Kel-F* 300 moulding powder' (Minnesota Mining and Manufacturing Co.) is ground, using solid carbon dioxide to cool the material, and the powder passing 100 B.S.S. and retained by 200 B.S.S. is collected. The column is prepared by adding 3 ml. of purified tributyl phosphate to 3 gm. of the '*Kel-F*' powder, mixing with a glass rod, and loading as a slurry in 5·5 *M* nitric acid into a burette 7 mm. in diameter containing a loose plug of cotton-wool above the tap. The slurry is agitated with a glass rod to release air bubbles, and 5·5 *M* nitric acid is run through the column to consolidate the contents. A loose plug of cotton-wool is placed over the material to prevent disturbance of the surface.

The sample solution, 5–10 ml., containing not more than 50 mgm. of uranium in 5·5 *M* nitric acid, is poured on to the column. The uranium is retained as a clearly defined yellow band at the top of the column and impurities are eluted by washing with three 10-ml. portions of 5·5 *M* nitric acid at a rate of flow of 1–2 ml. per min. The uranium is then eluted with 35 ml. of distilled water at the same rate and determined by a suitable method.

The column is reactivated by washing with 20 ml. of 5·5 *M* nitric acid. The tributyl phosphate is slowly eluted, but one column packing can be used for more than fifty determinations, and the *Kel-F* from exhausted columns may be used as support material after washing with carbon tetrachloride, and drying.

Most impurities are eluted rapidly, the peak of the elution being reached when 10–12 ml. of eluent have passed through the column. The peak for the elution of uranium with nitric acid is not reached until 200 ml. of eluent have passed through and there is a clear volume of about 40 ml. between the two peaks. In order to save time, the eluent is changed to water after the impurities have been eluted.

Uranium has been separated effectively from more than ten times its weight of chromium, copper, aluminium, nickel, vanadium, calcium, iron, molybdenum, tungsten, sodium, potassium, fluoride, phosphate, sulphate, chloride and from concentrated solutions of citric acid which complex uranium strongly. The method is applicable from the microgram- to the gram-level by proportional adjustment of the size of column. Recoveries at the level of 5 mgm. of uranium have been in excess of 99 per cent, which has been adequate for the purpose in hand. We are confident, however, that a quantitative recovery is possible, and the method is being further investigated. A full report of the work will be published.

The tributyl phosphate/nitric acid column has been used to separate uranium from some of its daughter products.

Thorium, plutonium IV and cerium IV are retained on the column after washing with nitric acid, but cerium can be separated after reduction by sulphur dioxide to cerium III.

By modifying the technique so as to use hydrochloric acid in place of nitric acid throughout, it has proved possible to separate plutonium from uranium The plutonium must be reduced to the trivalent form before loading on to the column. The uranium is retained on the column.

Evidence for the Existence of a Potassium Rhenium Hydride and its Bearing on the Nature of the (−1)-Oxidation State of Rhenium

THIS is a preliminary report of some observations we have made on the product of the reduction of potassium perrhenate with potassium metal in ethylenediamine–water solution. According to Bravo, Griswold and Kleinberg[1], and also Floss and Grosse[2], rhenium is reduced to the (−1)-oxidation state in this reaction, and the solid rhenide $KRe.4H_2O$ may be isolated from the products.

The reduction procedure and method of separating the unreacted potassium perrhenate ($KReO_4$) and the bulk of the potassium hydroxide from the product were as described by Bravo, Griswold and Kleinberg[1]. The grey-brown solid obtained in this manner was purified by dissolving it in an alkaline 10 : 2 methanol–water solution, centrifuging to settle out the brown-black solid matter (rhenium metal or a rhenium oxide), and then slowly adding the clear supernatant to a large excess of oxygen-free, anhydrous *iso*propanol. The result is a white precipitate which was successively extracted three times with *iso*propanol and then three times with anhydrous ethyl ether; after which it was pumped down for 2 hr. at 90° C. This product is stable in an inert atmosphere.

On treating the white solid or its solution in aqueous alkali (which is quite stable) with various oxidizing agents (hypochlorite, thallous ion, permanganate) gas evolution takes place. The gas evolved when a solution of the solid in 5 *M* potassium hydroxide reacted with 0·1 *M* potassium permanganate was shown, by mass-spectrometric analysis, to be pure hydrogen. The volume of hydrogen evolved on treating about 50-mgm. samples of the solid with 25 ml. of a solution 4·5 *N* in alkali and 1 *N* in permanganate is about 10 ml. at room temperature and atmospheric pressure. We find, as the mean of three measurements:

gram atoms H evolved/gram atoms Re $= 5 \cdot 54 \pm 0 \cdot 06$

In acid solution the solid decomposes with the evolution of hydrogen and the precipitation of rhenium metal. Treatment of about 55-mgm. samples with excess of dilute sulphuric acid yields about 20 ml. of hydrogen at room temperature and atmospheric pressure. As the mean of three measurements we find:

gram atoms H evolved/gram atoms Re $= 10 \cdot 05 \pm 0 \cdot 05$

The above results indicate that the white solid contains a hydride of rhenium. To confirm this, about 40 mgm. of the solid were dissolved in about 0·2 ml. of de-aerated 50 per cent potassium hydroxide solution, and the proton resonance spectrum was obtained with a high-resolution nuclear magnetic resonance spectrometer operating at a frequency of 60 Mc./s. The spectrum consists of two peaks separated by 14·7 parts per million. The low-field peak is very large and is due to the water–hydroxyl ion protons. The high-field peak is much smaller and can only be attributed to protons of a hydridic nature (H^-). The shift of the hydride peak with respect to the proton resonance of pure water is + 13·3 p.p.m. Wilkinson and co-workers have independently obtained a similar spectrum for the solution resulting from the reaction of aqueous potassium perrhenate with sodium amalgam (Wilkinson, G., personal communication). In addition, we have observed the proton resonance spectrum of the solid dissolved in deuterium oxide (heavy water) containing about 35 per cent sodium deuteroxide (NaOD) (no proton resonance could be observed on the solvent). Again the spectrum consists of only two peaks separated by 14·7 p.p.m. This shows that the solid contains H_2O or OH^- groups as well as hydridic protons. The fact that only two peaks occur indicates that alcohol and ethylenediamine are absent, and this is confirmed by chemical tests. The ratio of the intensity of H^- peak/intensity of $H_2O - OH^-$ peak $\simeq 2$. Hence the ratio H^-/H^+ in H_2O or $OH^- \simeq 2$; but it must be noted that the sample used in the deuterium oxide experiment had been standing under vacuum for about one month and may have been partially dehydrated.

These observations demonstrate the existence of a soluble rhenium hydride. This is the first example of a soluble transition metal hydride which does not also contain complexing groups such as $C_5H_5^-$, CO or CN^- attached to the metal ion (bis*cyclo*pentadienylrhenium hydride and rhenium carbonyl hydrides are known[3]). We believe that it is now no longer necessary to postulate the existence of the rhenide ion, Re^-, or an aquo complex of this ion, since all the properties of the apparent (−1)-oxidation state of rhenium[1,2,4] may be explained as being due to a hydride of a positive oxidation state of rhenium. Work on this problem is continuing, and it appears possible that more than one rhenium hydride may exist. Further details will be reported at a later date.

This work was supported in part by the U.S. Atomic Energy Commission.

Note added in proof. Two measurements of the area beneath the high-field proton-resonance peak in deuterated basic aqueous solvent gave 7·3 and 6·5 for the ratio of hydridic hydrogen atoms to rhenium atoms in the compound. The measurement, expected to be reliable to about 20 per cent, was calibrated by the addition of a known quantity of normal-isotopic water to the deuterated solvent.

Formation of Volatile Compounds on Gas–Liquid Chromatography Columns

THE communication by Weurman and Dhont[1] reporting the formation of volatile esters on gas–liquid chromatography columns using polyethylene glycol 600 prompts us to report our own findings with a similar stationary liquid phase.

When first preparing a column filling with polyethylene glycol 400, it was distributed on 'Celite 545' in a mixed solvent of acetone and diethyl ether which was afterwards removed by heating in an oven at 100° C. for 3 hr. During this period a strong smell of formaldehyde was noticed but this later disappeared, and the column was therefore packed and brought into use at 60° C. with nitrogen as carrier gas. The copper connexions of the thermistor detector became corroded and the base line irregular. The stock of polyethylene glycol 400 was afterwards tested and found to contain formaldehyde (chromotropic acid test) and formic acid (paper chromatogram by Dr. G. C. Whiting).

Since this time we have pre-treated the polyethylene glycol 400 as suggested by Adlard[2], namely, by heating to 100° C., but under a higher vacuum (0·01 mm. of mercury), for 16 hr. Satisfactory results have since been obtained, chromatograms of alcohols showing no abnormalities. It thus seems that polyethylene glycols as supplied by the manufacturers contain volatile impurities which should be removed before use as stationary phases. Our findings offer an explanation of the source of formic acid causing the esterification observed by Weurman and Dhont.

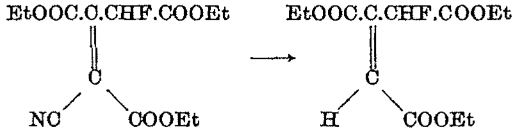
Triethyl α-Fluoroaconitate

THE current theory on the mode of action of fluoroacetate[1] implies the lethal synthesis of fluorocitrate which poisons the enzyme aconitase, thus preventing the catabolism of citrate to aconitate; it seemed of interest to prepare and study α-fluoroaconitic acid, HOOC.CHF.C(COOH)=CH.COOH. Triethyl fluorocitrate, which would appear to be a suitable starting material, has been prepared in a facile reaction, namely, by the Reformatzky reaction between diethyl oxalofluoroacetate and ethyl bromoacetate[2], but our attempts to dehydrate this compound failed to give a defined product.

Better results were obtained by the condensation of diethyl oxalofluoroacetate with ethyl cyanoacetate in the presence of piperidinium acetate. The product so obtained (I) gave, upon treatment with alcoholic sulphuric acid, directly the desired triethyl α-fluoroaconitate (II).

$\mathrm{EtOOC.CO.CHF.COOEt} + \mathrm{NC.CH_2.COOEt} \rightarrow$



$$\begin{array}{c}\mathrm{EtOOC.C.CHF.COOEt}\\ \| \\ \mathrm{C} \\ \mathrm{NC}\diagup\quad\diagdown\mathrm{COOEt}\end{array} \longrightarrow \begin{array}{c}\mathrm{EtOOC.C.CHF.COOEt}\\ \| \\ \mathrm{C} \\ \mathrm{H}\diagup\quad\diagdown\mathrm{COOEt}\end{array}$$

I II

We have not succeeded in hydrolysing (II) without far-reaching degradation of the molecule. However, the biological properties of (II) as such will be of interest, as the complications inherent in the possible stereochemical forms of fluorocitrate[3] are not to be feared in (II).

Triethyl γ-cyano-α-fluoroaconitate (*I*). A mixture of 21 gm. of diethyl oxalofluoroacetate[4], 14 gm. of ethyl cyanoacetate, 0·5 ml. of acetic acid and 0·1 ml. of piperidine was heated for 20 hr. at 100° in a vacuum of 35 mm. After 6 and again after 13 hr. of this period, 0·05 ml. of piperidine and 0·25 ml. of acetic acid were added. The product was subjected directly to distillation under 0·05 mm. pressure. The ester (I) boiled at 160–162° and formed a colourless oil; yield, 12 gm. (40 per cent).

Analysis: Calculated for $C_{13}H_{16}NO_6F$: C, 51·8; H, 5·3; N, 4·7; F, 6·3.

Found: C, 51·5; H, 5·6; N, 4·3; F, 5·9.

Triethyl α-fluoroaconitate (*II*). A mixture of 5 gm. of concentrated sulphuric acid and 1 gm. of water was added to a solution of 12 gm. of (I) in 20 ml. of anhydrous alcohol, refluxed for 5 hr. and poured into cold 10 per cent sodium hydrogen carbonate solution. Extraction with ether, drying and distillation gave 5 gm. (45 per cent) of triethyl α-fluoroaconitate (II), b.p. 115–117° (0 1 mm.).

Analysis: Calculated for $C_{12}H_{17}FO_6$: C, 52·2; H, 6·2; F, 6·9.

Found: C, 52·4; H, 6·3; F, 6·5.

Colorimetric Determination of Amino-acid Concentration

A VERSATILE method of amino-acid determination is that in which amino-acid solutions are incubated with cupric orthophosphate in suspension. The resulting solution contains copper in proportion to the total molarity of amino-acids and the copper is determined by any suitable method. The methods used have included iodometric titration[1] and the use of cupric phosphate labelled with copper-64 followed by the determination of the activity in the supernatant[2]. The latter method is of particular use for the continuous determination of amino-acids in chromatographic eluates.

I have determined the copper colorimetrically using sodium diethyl dithio carbamate as the copper reagent. The colour produced is stable and has a maximum absorption at 440μ. The stages in the procedure are as follows.

(1) 0·1 ml. of the sample, 3·0 ml. of cupric orthophosphate suspension (1 per cent aq.), 2·0 ml. of B.D.H. Universal buffer solution, *p*H 7·0[3] are incubated overnight in a centrifuge tube. A reagent blank is used with distilled water replacing the sample. Using finely divided cupric orthophosphate (B.D.H.) shaking was found to be unnecessary even when using conical centrifuge tubes, the recovery figures being identical in procedures with and without shaking. The tubes are centrifuged to sediment the cupric orthophosphate and a part of the supernatant withdrawn for colour development.

(2) 0·1 ml. of the supernatant from (1), 3 0 ml. of B.D.H. Universal buffer *p*H 7·0, 0·1 ml. of sodium diethyl dithio carbamate 1·0 per cent aq., are mixed at room temperature. The optical density at 440μ does not increase after 15 min. from mixing, and is read at any convenient time, being stable for at least 24 hr. A 'Unicam' *S.P.* 500 or similar instrument is used with a violet filter. If the colour is too dense or if precipitation occurs, the supernatant from stage (1) is diluted and stage (2) repeated. The results obtained show that, due to the large excess of cupric orthophosphate in stage (1), the relationship [copper]/[amino-acid] is linear over a wide range, so that dilution is permissible with no inherent inaccuracy. The 'recovery' of added amino-acids was 100 per cent ± 2 per cent over a concentration range of 50–1,000 μgm./ml. α-alanine. This method has proved to be useful in enzyme kinetic work.

Nielsen[4] describes the estimation of proteins by a related method, involving the removal of amino-acids before reaction of the proteins and trichloracetic acid-insoluble peptides with cupric sulphate. Excess copper is removed by precipitation as cupric orthophosphate and the copper in solution as a peptide complex is estimated using diethyl dithio carbamic acid. In the method here described, peptides and proteins are found not to give any appreciable copper uptake from cupric orthophosphate, the results for amino-acid concentration obtained from solutions containing amino-acids, peptides and proteins being within 2 per cent of those obtained by formol titration and by the Folin–Ciocalteau method[5].

BIOCHEMISTRY

Volatile Amines in Brain

WE have reported previously the isolation and identification of the volatile amine 2-dimethylaminoethanol in the brain of man and pig and in other biological material[1,2]. Bremer and Greenberg's[3] report on its presence in rat-liver phospholipids has substantiated our findings. During our investigation several volatile amines—besides the previously identified volatile bases ammonia[4] and 2-aminoethanol[5]—were isolated from brain tissue and we became interested in analysing the brain for other normally occurring volatile amines.

Brain tissues from cat, pig and man, processed 1, 30 and 360 min. after death, respectively, were used. The extraction was carried out by three different methods to get a more accurate picture of the amines present. Accordingly, the tissue was extracted 3–4 times with either 80 per cent ethanol, adjusted to *p*H 2 with hydrochloric acid (EtOH–HCl), as described earlier[2]; or with acetone followed by 80 per cent ethanol (acetone–EtOH); or with 5 per cent trichloracetic acid. The supernatant contained the unbound or free amines; the precipitate, the bound amines. Since we were primarily interested in the unbound amine content of the brain, most of the following procedures involved only the supernatant fractions. In the case of the trichloracetic acid treatment the aqueous solution was extracted with ether and passed through an anion exchange column ('Dowex 2', Cl⁻ form), in order to remove the trichloracetic acid. The supernatants were individually concentrated *in* *vacuo* and subjected to a fractional steam distillation in saturated barium hydroxide solution or, in the case of the trichloracetic acid extract, in saturated sodium carbonate solution. The distillation and the subsequent procedures, used for obtaining the volatile amine fractions as hydrochlorides, were the same as previously reported[3]. To liberate the bound amines from human and pig brain tissue the (EtOH–HCl) precipitate was hydrolysed in saturated aqueous barium hydroxide and the bases fractionated according to the procedure described[3].

The different fractions were analysed by gas-chromatography, paper-electrophoresis and paper-chromatography. Gas-chromatography was performed with argon as the carrier gas and an ionization detector which has a usable sensitivity of 10^{-10}–10^{-11} mole. The insensitivity of the ionization detector to water allowed us to analyse the free amines in aqueous solution. The free amines were released from their hydrochloride salts with 2 *N* aqueous sodium hydroxide and injected into the gas-chromatograph, where they were separated by a carbowax-on-alkaline-chromosorb column[4]. The paper-electrophoretic and paper-chromatographic separations were carried out as previously described[5], using the hydrochloride salts of the amines.

The gas-chromatograms of the unbound amine fractions from the EtOH–HCl and acetone–EtOH extracts of pig brain and the trichloracetic acid extract of cat brain, as well as the bound amine fractions from pig brain (EtOH–HCl), showed quite similar patterns. 2-Dimethylaminoethanol, 2-aminoethanol and ammonia were present in these fractions plus 4–8 as yet unidentified amines. One of these amine-peaks recurs in the gas-chromatograms of all specimens and indicates the presence of 2-methylaminoethanol. Extracts from a human brain (EtOH–HCl) showed in the unbound and bound amine fractions an additional peak in large amounts which could be identified as 2-diethylaminoethanol.

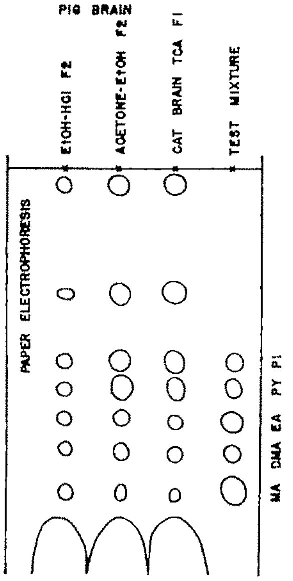

Fig. 1. Paper electrophoretic separation of brain fractions and test mixture. The migration values (where cysteine has a migration value of 0 and methylamine of 1) and dye reactions of the amines are methylamine (MA) 1·0, ninhydrin red-violet; dimethylamine (DMA) 0·90, ninhydrin red-violet; ethylamine (EA) 0·79, ninhydrin blue-violet; pyrrolidine (PY) 0·69, ninhydrin yellow, isatin blue; piperidine (PI) 0·50, ninhydrin violet, red fluorescence under ultra-violet light

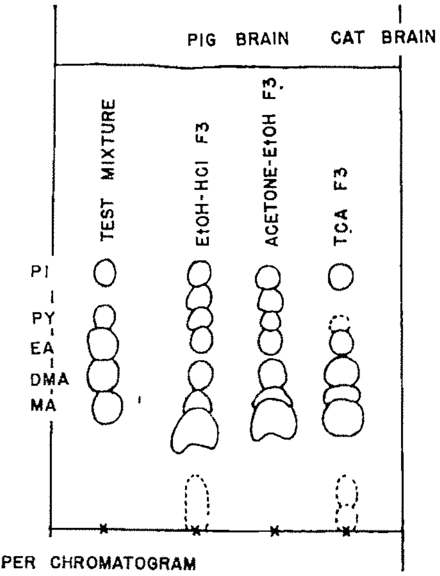

Fig. 2. Paper chromatographic separation of brain fractions and test mixture. The migration values are: methylamine (MA) 0·27; dimethylamine (DMA) 0·32; ethylamine (EA) 0·40; pyrrolidine (PY) 0·44; piperidine (PI) 0·53. The dye reactions were the same as in Fig. 1

It was learned later that the patient whose brain was analysed received treatment with 110 mgm. of procaine (in the form of procaine penicillin) every 6 hr. prior to death. This probably accounts for the large amount of 2-diethylaminoethanol present. Also, the occurrence of this substance in the bound form suggests the possibility of its incorporation into phospholipids.

Figs. 1 and 2 represent the paper-electrophoretic and paper-chromatographic separation of the pig and cat brain fractions, obtained by the different extraction procedures. It can be seen that these fractions are almost identical. By comparison with known amines, five of the spots could be identified as methylamine, dimethylamine, ethylamine, pyrrolidine and piperidine. These five substances were present in the free amine fractions of the EtOH–HCl and acetone–HCl extracts from pig brain and in the free amine fractions from cat brain, obtained by trichloracetic acid extraction. In the bound fractions from pig brain (EtOH–HCl) methylamine, dimethylamine, ethylamine and pyrrolidine were identified. The human brain (EtOH–HCl extraction) contained in the free amine fractions methylamine, dimethylamine, ethylamine and piperidine; in the bound amine fractions piperidine was missing. The migration values and dye reactions of the substances from the brain extracts and the mixture of reference compounds coincided in the chromatographic and electrophoretic systems. In addition, the reference compounds were mixed with the brain fractions and the chromatographic and electrophoretic concordance was determined from the increased spot intensities. The results were further substantiated by a two-dimensional electrophoretic-chromatographic separation on one paper[6]. Besides the identified amines this separation revealed a substantial number of unidentified amines. The largest number was found in the EtOH–HCl extract of pig brain, 12 unknown spots in the free amine and 11 in the bound amine fractions. This might be due to the relatively large amount of tissue analysed, which allowed detection of amines present in low concentrations.

Table 1. APPROXIMATE AMOUNTS OF UNBOUND VOLATILE AMINES IN BRAIN (IN FREE AMINE FORM)

	Pig brain		Cat brain
	EtOH–HCl (μgm./kgm.)	Acetone–EtOH (μgm /kgm)	TCA (μgm./kgm.)
Methylamine	110	40	790
Dimethylamine	550	290	2,460
Ethylamine	90	60	360
Pyrrolidine	20	10	20
Piperidine	30	180	840
Dimethylamino-ethanol	45	40	80

Table 1 gives the approximate amounts of the volatile amines which we found in brain tissue. The value for 2-dimethylaminoethanol is most exact because it was calculated from the peak which appeared on the gas-chromatograms, whereas the remaining substances have been estimated from the density of the spots as they appeared in paper-chromatography and paper-electrophoresis. Furthermore, since much more pig brain than cat brain was assayed, the figures for pig brain may be more representative than those for the cat brain.

Further work is planned to confirm these results with methods which exclude possible hydrolysis of unstable substances and to learn more about the significance of the occurrence of these substances in the various organs of animals under varying physiological conditions.

We are indebted to Dr. Carl C. Pfeiffer for his interest and support in this work, which was also supported in part by grant *M*-875 Mental Health Institute, National Institutes of Health, the U.S. Public Health Service, and by grants from the Geschickter Fund for Medical Research and the Riker Laboratories, Los Angeles, California.

Methanesulphonic Acid Derivatives of Central Stimulant Drugs

AMONG the substances recently introduced in the therapy of mental depression which stimulate the central nervous system, iproniazide (1-*iso*nicotinoyl-2-*iso*propyl-hydrazine) has been the drug longest under investigation[1]. Its stimulating properties have been discovered by studying this drug as a tuberculostatic agent; and during this work toxic psychoses have been observed as side-effects.

A great number of hydrazine derivatives tested afterwards reacted in the same way and showed a more or less pronounced inhibition on the monoamine oxidase, an enzyme involved in the metabolism of serotonin, epinephrine and other amines. These substances unfortunately produce a wide variety of side-effects, so that many physicians refuse to use them.

Table 1. TOXICITY (*LD*50)

Drug	Administered orally (rats) (mgm./kgm.)	Administered intravenously (mice) (mgm./kgm.)
(1) Iproniazide	365	820
(2) 2-Hydrazino-propane hydrochloride	80	315
(3) 1-Phenyl-2-propyl-hydrazine hydrochloride	13	—
(4) Sodium salt of methane-sulphonic acid of (2)	330	500
(5) Sodium salt of methane-sulphonic acid of (3)	56	—

Table 2. INHIBITION *in vivo* OF THE MONOAMINE OXIDASE
Dose of drug producing 50 per cent inhibition, administered endoperitoneally 6 hr. before the animals were killed (ref. 6)

Drug	Brain (mgm.)	Liver (mgm.)
(1) Iproniazide	6 2	1 2
(2) 1-Phenyl-2-propyl-hydrazine hydrochloride	0·4	0 45
(3) Sodium salt of methane-sulphonic acid of (2)	0·70	0·70
(4) Sodium salt of methane-sulphonic acid of 2-hydrazino-propane	2·45	0·61

Table 3. BRAIN SEROTONIN-LEVELS OF RATS AFTER ADMINISTRATION OF DRUGS 6 HR. BEFORE THE ANIMALS WERE KILLED (REF. 6)

Drug	Dose (mgm./kgm.)	No. of animals	Brain serotonin (γ/gm. fresh weight ± S.E.)
Control	—	15	0·470 ± 0 021
(1) Iproniazide	100	10	0·994 ± 0 038
(2) Sodium salt of methanesulphonic acid of 2-hydrazino-propane	114	10	1·400 ± 0·045
(3) 2-Hydrazino-propane hydrochloride	61	10	1·860 ± 0 065

In order to get a therapeutically more suitable drug with a lower toxicity we adopted a method which has already given good results with other drugs[6], namely, transformation into methanesulphonic acid derivatives. Thus we transformed 2-hydrazino-propane[3] and 1-phenyl-2-hydrazino-propane[4] (both substances are considerably more active than iproniazide) into the above derivatives. We treated 2-hydrazino-propane and 1-phenyl-2-hydrazino-propane with formaldehyde (40 per cent) and then with sulphur dioxide to obtain the corresponding methanesulphonic acids, which we neutralized with sodium bicarbonate to form the sodium salt of methanesulphonic acid of 2-hydrazinopropan (I) and the sodium salt of methanesulphonic acid of 1-phenyl-2-hydrazino-propane (II).

The sodium salts have no definite melting point, but the acid corresponding to (I) melts at 158°, that of (II) at 136–138° [5]. Analysis of the acid of (I) gave:

Calculated for $C_4H_{12}N_2SO_3$: C, 28·55; H, 7·19; N, 16·42; S, 18·50.

Found: C, 28·33; H, 7·16; N, 16·42; S, 18·50.

Analysis of the sodium salt of (I) gave:

Calculated for $C_4H_{11}N_2SO_3Na.2H_2O$: N, 12·37.

Found: N, 12·85.

Analysis of the sodium salt of (II) gave:

Calculated for $C_{10}H_{15}N_2SO_3Na.3H_2O$: N, 8·76; S, 10·02.

Found: N, 8·40; S, 9·82.

Table 1 shows a lower toxicity compared to the initial substances, and Tables 2 and 3 show in the same time a high activity with regard to the inhibition of monoamine oxidase and to the increase of the brain serotonin.

Th. Bersin[7] has attributed this surprising change of the pharmacological properties of the methanesulphonic acid derivatives to the transformation of a cationic drug into an anionic one:

$$R\text{NHNH}_3^+ \rightarrow R\text{NH.NH.CH}_2\text{SO}_3^-$$

This transformation presumably changes the penetration and excretion of the drug.

Release of Iron from Conjugates in Foods

IRON in food of both animal and plant origin must be released from its conjugates before it can be absorbed from the gastro-intestinal tract. There is also evidence that it must be in the reduced ferrous state before assimilation. The total iron and the percentage easily available as ferrous iron are therefore both important in assessing the dietary value of an iron-containing food, and for this reason most tables of food values show the total iron and that amount which reacts with α-α′-dipyridyl. These measurements, however, do not recognize the possible effects of cooking and of intestinal enzymatic digestion in releasing iron from its conjugates.

Kaldor demonstrated that 12–13 per cent of the total iron in hæmoglobin is liberated by acid peptic digestion of heat-denatured blood, whereas only approximately 0·1 per cent could be extracted with saline from uncooked blood[1]. Brading, Kaldor and George also showed that more iron was absorbed by rats from cooked than from uncooked blood administered into the stomach[2]. These observations have been based solely on hæmoglobin, although Moore and Dubach have shown that iron-59 incorporated into various foods is absorbed from the gastro-intestinal tract[3]. The part played by acid peptic digestion *in vitro* in liberating iron from cooked foods has now been extended to a number of other materials.

The total iron content was determined on acid digests of the foods. Aliquots of calves' liver and flour were heated to 95° C. for 30 min., and of silver beet and sultanas to 100° C. for 30 min. They were then homogenized in the water or saline in which they had been heated. One aliquot of each homogenate was incubated with water or saline at 37° C. for 60 min. and another with pepsin at a final concentration of 0·64 per cent and hydrochloric acid at a concentration of 0·32 *N* (*p*H 1·5). The supernatant of the first treatment is referred to as the neutral extract and of the second as the acid peptic digest. The iron content was determined in each case, using the ortho-phenanthroline method described by Kaldor[4].

The importance of cooking hæmoglobin is seen from the results in Table 1, which also demonstrate the role of peptic digestion and the variability with which iron is released from different foods. Higher percentages are liberated from liver rather than from hæmoglobin, and the iron from the liver was shown to be derived more from the tissue iron (hæmosiderin and ferritin) rather than from the contained blood. The plant products yielded greater percentages than did hæmoglobin, but smaller absolute amounts per gram because of the lower total iron content. Phytic acid in silver beet did not prevent liberation of iron, but the amount of iron released was greater from old than from young leaves, and greater from stored than from fresh leaves.

These findings suggest a more rational basis for the compilation of dietary tables of iron values. However, the amount of iron released by peptic digestion of cooked food is not the only factor determining the amount of iron actually absorbed following ingestion of the food. The role of the other enzymes present in the gastro-intestinal tract has not been investigated. The needs of the body also have some regulating

TABLE 1. EXTRACTION OF IRON FROM FOODS

Optical Rotation and Configuration of Poly-L-Tyrosine

IN a recent communication[1], Downie, Elliott and Hanby report that the optical rotatory dispersion of poly-L-tyrosine is unusual and, as a result, its configuration cannot be assigned by analogy with polypeptides having normal dispersion characteristics However, they interpret their data, together with unspecified infra-red spectral and X-ray diffraction observations of films, as indicating that "it is more probable that in dilute solutions in pyridine, in dimethyl formamide, and in aqueous alkali, poly-L-tyrosine is in a random coil configuration". Our study of this problem has led to somewhat different conclusions: that the configuration in pyridine and dimethyl formamide is that of the α-helix, whereas in alkaline solution the configuration is dependent on *p*H, indicative of the random-coil configuration. The basis of the configurational assignments will be published elsewhere in detail, but we wish to summarize them here and report the optical rotatory characteristics of the two forms.

Poly-L-tyrosine samples were prepared by modification of the Katchalski–Sela[2] procedure and shown to have molecular weights in the range 30,000–40,000 by combined sedimentation and viscosity measurements. In this molecular-weight range such measurements alone cannot establish configuration. Flow-birefringence measurements did, however, show that in dimethyl formamide/glycerol (3 : 1 by volume) the polymer exhibited strong positive birefringence. The same polymer sample when dissolved in aqueous alkali (*p*H 12·5, 1 *M* sodium chloride) – glycerol solution of equivalent viscosity failed to show any birefringence.

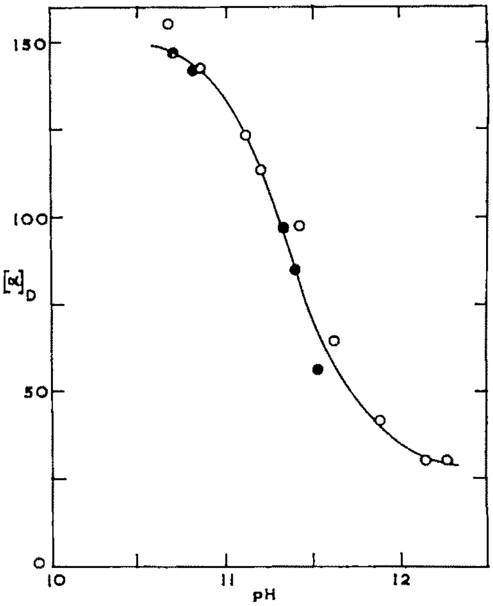

Fig. 1. Dependence on *p*H of specific optical rotation (at 589 mμ) of poly-L-tyrosine. All measurements were made in the 0·2 *M* sodium chloride. ● and ○ denote different polymer samples

The specific rotation of poly-L-tyrosine was measured in the *p*H range where it is soluble in aqueous solution, that is, above *p*H 10·6. The results, shown in Fig. 1, indicate a sharp fall in specific rotation coincident with the ionization of the tyrosine residue. The specific rotation of tyrosine itself changes only a few degrees in this same *p*H range. Since large changes in the optical rotation of poly-L-glutamic acid[3] and poly-L-lysine[4] were accompanied by a helix-coil transition, it was inferred that the same was true for poly-L-tyrosine. This was tested by measuring the sedimentation constant and specific viscosity as a function of *p*H at two different ionic strengths (0·2 and 1·0). Below *p*H 11·3, there was no dependence on ionic strength, indicating a rigid configuration. Above this *p*H the values were increasingly dependent on ionic strength, as would be expected for a flexible coil configuration. This supporting evidence leads to the conclusion that the configuration is helical near the solubility limit and randomly coiled beyond *p*H 12.

One can expect to observe the same helix-coil transition in organic solvents as the proportion of weak to strong hydrogen-bonding solvents is increased. This was found by measuring the specific rotation, $[\alpha]_D$, as a function of the concentration of dichloroacetic acid in dichloroacetic acid – dimethyl formamide mixtures[5]. The value of $[\alpha]_D$ fell sharply from 190° to 40° in the vicinity of 75 per cent dichloroacetic acid[6]. Since the strong birefringence indicated the helical form in dimethyl formamide, and since dichloroacetic acid has been shown to induce the solvated, random-coil configuration[7] and since, furthermore, the $[\alpha]_D$ values in these two solvents match the values of the two similarly assigned configurations in aqueous solution, it can be concluded that the α-helical configuration exists in dimethyl formamide, pyridine and at *p*H 10·7 in aqueous solution, while the random-coil configuration exists at high concentrations of dichloroacetic acid and above *p*H 11·8.

Having made this configurational assignment, it is of interest to examine the rotatory dispersion of the two forms in order to assess the magnitude of the perturbation produced in dispersion constants by the introduction of a strong chromophoric group close to the peptide bond chromophore. The relevant data for each configuration in two quite different solvents are listed in Table 1. The constant λ_0 was taken as 212 mμ in determining b_0 and the resulting plots were linear over the wave-length range investigated (450–700 mμ).

It is seen that each of the three constants has characteristic values for the two configurations. $[\alpha]_D$ for the helical form is more positive than the coil form by 120–150°. When data on this difference for six other, normally behaving, polypeptides is averaged and corrected to the residue weight of tyrosine, a predicted difference of only 50° is found.

Table 1. ROTATORY DISPERSION CONSTANTS OF POLY-L-TYROSINE

Solvent	$[\alpha]_D$	λ_0	b_0
0·15 *M* NaCl, *p*H 10·85	+ 150°	237 mμ	+ 540°
0·15 *M* NaCl, *p*H 11·20	+ 103	263	+ 520
0·15 *M* NaCl, *p*H 11·88	+ 38	316	+ 480
0·15 *M* NaCl, *p*H 12·27	+ 28	330	+ 450
Pyridine	+ 189	230	+ 560
Dimethyl formamide	+ 184	235	+ 550
Dichloroacetic acid			
,, with 20 per cent dimethyl formamide	+ 73	330	+ 470
,, with 4 per cent dimethyl formamide	+ 36	—	—

Thus, the sign of the difference for poly-L-tyrosine is normal, but the magnitude is about 2·5 times that normally observed.

The constant λ_0 usually has a value of about 210 mμ for the coil form, and increases to 300 mμ for the helix form. The behaviour found here is approximately the inverse.

The constant b_0 normally has a value of about −630 for the helical form and zero for the coil form. For poly-L-tyrosine we find instead positive values for both, and little dependence on configuration.

From this it is clear that the proximity of the tyrosine residue to the peptide bond greatly modifies the optical rotatory properties of both the helical and the coil forms. The close coupling between the two chromophores in either configuration, plus the fact that the primary helical arrangement of peptide bonds necessarily imposes a second helical arrangement on the chromophoric side-chains (tyrosine), introduces sufficient new pair-wise interactions to make the contribution of the original primary helix of peptide bonds to the optical rotatory properties essentially unrecognizable.

It might be conjectured that some of the changes in dispersion constants may be due to the helical form having the opposite screw sense to that normally occurring[7]. However, co-polymer studies to be described elsewhere rule out this possibility.

A New Metabolite of Chloramphenicol

THE metabolism of chloramphenicol has been studied extensively in animals and in human subjects, with the recognition of the glucuronide as the principal metabolic product[1]. In addition, a small amount of the amino diol hydrolysis product and free chloramphenicol were found in the urine[1,2]. However, little attention has been given to the metabolism of this compound where deficiencies exist in the conjugating mechanism. The normal adult cat has been reported to be deficient in its capacity to form glucuronides with a number of synthetic substrates[3], and newborn animals generally have a low order of activity in the enzyme systems responsible for detoxication processes[4]. Consequently, the metabolism of chloramphenicol was investigated in the cat and in newborn human infants.

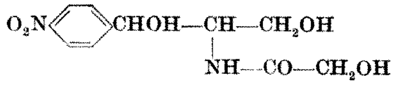
Following oral administration of chloramphenicol palmitate, the urine of adult cats and newborn infants was examined by paper chromatography. The solvent system was water-saturated butanol containing 2·5 per cent phenol and 2 per cent pyridine[1]. Strips of Whatman No. 1 paper were used in the descending method, and nitro compounds were detected by reduction with titanous chloride, diazotization and coupling as described elsewhere[1]. Aromatic nitro compounds were found in positions corresponding with chloramphenicol, the amino diol hydrolysis product of chloramphenicol, and the glucuronic acid conjugate. In addition, a fourth band located at R_F 0·70–0·75 was observed in cat urine and in the urine of newborn infants. A similar band was later observed in the urine of normal rats.

The presence of a glucuronide band in cat urine was of considerable interest in view of earlier reports concerning the absence of conjugation with phenolic compounds[3]. It is possible that conjugation of the terminal aliphatic alcohol group of chloramphenicol with glucuronic acid may occur through a different mechanism. The glucuronide nature of the product was confirmed by spraying the paper chromatograms with a solution of β-glucuronidase. After incubation for a few hours in a moist atmosphere, the strips were placed upon agar plates seeded with *Sarcina lutea*. Antimicrobial activity was found in the position corresponding with the chloramphenicol–glucuronide band, which showed no antimicrobial activity prior to hydrolysis.

The appearance of a new metabolite of chloramphenicol was also of interest because of its potential toxicity. This compound was isolated from cat urine, using a combination of methods involving adsorption on to charcoal, fractional elution with acetone–water mixtures, 24-plate counter-current extraction with a two-phase solvent system consisting of 270 ml. water, 30 ml. *iso*propanol and 300 ml. ethyl acetate, and by paper chromatography. The final crystalline product had an off-white colour and gave a melting point of 155–156° C. (uncorr.). It showed 4 per cent of the antimicrobial activity of chloramphenicol against *Shigella sonnei* in turbidimetric assays. $E(1\%, 1\text{ cm.}) = 367$ at 274 mμ (ethanol).

Analysis: Calc. for $C_{11}H_{14}N_2O_6$ (270·24): C, 48·89; H, 5·22; N, 10·37. Found: C, 49·26, 49·34; H, 5·38, 5·34; N, 10·44.

The analytical results are in good agreement with the structure for D(−)*threo*-1-*p*-nitrophenyl-2-hydroxyacetamido-1,3-propanediol:



$$O_2N{-}C_6H_4{-}CHOH{-}\underset{\displaystyle NH{-}CO{-}CH_2OH}{\underset{|}{CH}}{-}CH_2OH$$

The metabolite is a glycolic acid amide analogue of chloramphenicol, apparently resulting from dehalogenation and reduction of the dichloracetate group in the parent compound. This analogue was prepared by synthesis, using the acid chloride procedure described by Rebstock[5]. The product showed the same melting point and mixed melting point as the metabolite from cat urine. $E(1\%, 1 \text{ cm.}) = 375$ at 274 mμ (ethanol). The infra-red absorbance spectra of the two preparations were identical, and they showed the same solubility characteristics in the counter-current extraction system already described, as well as having the same R_F values in paper chromatograms, and the same antimicrobial activity. The metabolite present in the urine of newborn human infants was also isolated by the same procedure, and proved to be identical with the product from cat urine in its counter-current distribution, paper chromatography, and antimicrobial activity.

Preliminary acute toxicity data obtained by intravenous administration of the synthetic product gave an $LD50$ value of $2{,}950 \pm 81$ mgm./kgm. in rats, and $2{,}950 \pm 72$ mgm./kgm. in mice, indicating that the metabolic product has a very low order of toxicity.

Effect of Glycosylation on the Enzymic Oxidation and Translocation of Flavonoids

There is a possibility that a planar structure may be one of the factors which determines the ability of a flavonoid to function as a substrate for plant polyphenoloxidases. It is also possible that a planar structure may adversely affect the ease of translocation of flavonoids in vegetable tissues.

As a result of an extensive study of the paper chromatographic behaviour of phenolic substances it has been established that all flavonoids with a planar structure have zero R_F in water, or in aqueous solvents containing up to 2 per cent of acid[1]. The molecular model in Fig. 1 illustrates the planar structure of quercetin. Other polynuclear phenols with 'flat' molecules, for example, ellagic acid, resveratrol and galloflavin, have also been shown to have zero R_F values in water. It is known that cellulose absorbs phenolic substances, and it appears that when a molecule contains two phenolic rings in the same plane the adsorption by cellulose is sufficient to prevent elution of the adsorbed substance by aqueous solvents.

The R_F values in aqueous solvents of substances such as gallic and caffeic acids are significantly increased by combination with glucose and quinic acid.

	R_F in 2 per cent acetic acid
Gallic acid	0·44
Glucogallin	0·64
Caffeic acid	0·25
Chlorogenic acid	0·56

As the R_F values in water of flavonol-3-glycosides are significantly greater than zero[2], it was originally assumed that the increased R_F was due to combination with water-soluble sugar residues. However, it has been found that both kaempferol-4′-arabinoside and quercetin-4′-glucoside have zero R_F values, and Geissmann has also recorded zero R_F in water for quercetin-7-glucoside (quercimeritrin)[3].

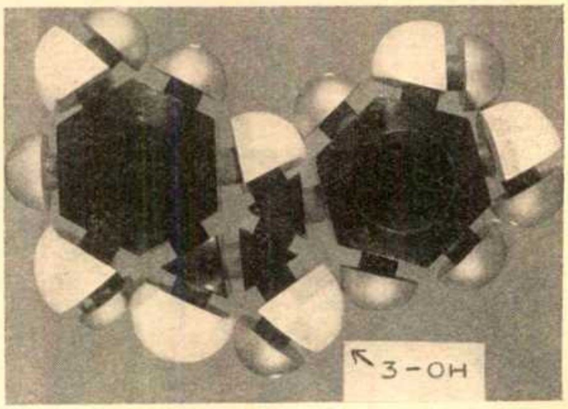

Fig. 1. Planar structure of the quercetin molecule built up from Courtauld's atomic models. Note that the hydrogen atom of the 3-hydroxyl group can only just be accommodated in the planar structure

The introduction of a sugar residue into the 4′ or 7 positions of a flavonol does not destroy the planarity of the molecule. On the other hand, as will be apparent from an inspection of the molecular model of quercetin, substitution of a large group in the 3-position cannot be achieved without a loss in planarity. Glycosylation only increases R_F values in aqueous solvents if in the 3-position, so that it appears that the increase is a consequence of loss of planarity and not to combination with a large water-soluble group.

It was shown by Baruah and Swain that potato polyphenoloxidase catalysed the oxidation of quercetin, myricetin and luteolin, but that the 3-glucosides of quercetin and myricetin were not oxidized[4]. This confirmed and extended earlier work by Roberts and Wood[5]. These results suggest that plant oxidases act preferentially upon flat molecules, a planar structure facilitating adsorption by the active enzyme surface. One might therefore anticipate that glycosides of luteolin, quercetin and myricetin might function as substrates so long as the sugar group was not in the 3-position, and it has been shown by Baruah and Swain[4] that the 7-diglucoside of luteolin (chærophyllin) undergoes oxidation in the presence of the potato oxidase. However, it was also stated that quercimeritrin was not oxidized, and this is inconsistent with the hypothesis advanced.

Samples of these two flavonoids were made available by Dr. Swain, and, as expected, it was found that chærophyllin had zero R_F in 2 per cent acetic acid. However, the substance labelled quercimeritrin was almost certainly inaccurately described, for it was resolved by two-way paper chromatography into at least five components, only one of which had zero R_F in aqueous solvents. It has been confirmed in this laboratory that an authentic specimen of quercimeritrin has an R_F of zero in 2 per cent acetic acid, and it may be safely concluded that Baruah and Swain's findings for quercimeritrin are incorrect. In summarizing the relation between substrate activity and R_F values in aqueous solvents (Table 1), results for quercimeritrin have not therefore been included.

The strong adsorption of flavones and flavonol aglycones by cellulose may well restrict their mobility

Table 1. SUBSTRATE ACTIVITIES AND R_F VALUES IN AQUEOUS SOLVENTS OF FLAVONOIDS

Substrate	Structure	R_F value	Oxidized by enzyme
Quercetin	Planar	0·00	Yes*
Quercetin-3-rhamnoside	Non-planar	0·19	No
Quercetin-3-rhamno-glucoside	Non-planar	0·29	No
Myricetin	Planar	0·00	Yes
Myricetin-3-rhamnoside	Non-planar	0·23	No
Luteolin	Planar	0·00	Yes
Luteolin-7-diglucoside	Planar	0·00	Yes

* Roberts and Wood (ref. 5) stated that quercetin was not oxidized by the tea oxidase. This was an inaccurate observation due to the very low solubility in water of quercetin.

in plant tissues, and it is suggested that glycosylation in the 3-position is necessary for translocation to take place. A paradoxical situation may now arise, for the planarity of the molecule, which is necessary for any physiological activity dependent upon enzymic oxidation, will hinder translocation. On the other hand, the more mobile glycoside may be physiologically inactive unless there is a glycosidase present to regenerate the active aglycone. Considerations such as these may also be relevant to the activity of certain flavonoids on vascular resistance or capillary permeability in animals[6,7].

I wish to thank Dr. T. Swain for helpful discussions, and Dr. D. E. Hathway and Profs. R. D. Haworth and L. Hörhammer for specimens of resveratrol, galloflavin and flavonol-4′-glycosides. Thanks are also due to the Indian Tea Association for permission to publish this communication.

Need for Inorganic Phosphate in Oxidations stimulated by Dinitrophenol

Recently we have reported, in disagreement with the widely accepted view, that the maximal rate of oxygen uptake by respiring rat-liver or rat-heart mitochondria with glutamate as substrate is not obtained with 2,4-dinitrophenol unless phosphate is also present[1]. With succinate as substrate, on the other hand, the same initial rate of oxygen uptake was found with dinitrophenol as with inorganic phosphate. We concluded that a link in the respiratory chain between glutamate and cytochrome *b* required phosphate even in the presence of dinitrophenol, a conclusion which seemed to have important implications for theories of the mechanism of the uncoupling of oxidative phosphorylation by dinitrophenol.

We now wish to report that further studies have provided evidence that dinitrophenol can replace inorganic phosphate in the respiratory chain. There is, therefore, no need to modify our earlier view[2] that dinitrophenol reacts with an energy-rich intermediate in oxidative phosphorylation formed prior to the intervention of inorganic phosphate.

The new evidence we have obtained is:

(1) Substrates, such as malate and β-hydroxybutyrate, which operate through nicotinamide–adenine dinucleotides, are oxidized at the same rate in the presence of 2,4-dinitrophenol alone as with dinitrophenol and inorganic phosphate together.

(2) The results with glutamate are explained by the finding that a large part of the measured oxygen uptake with this substrate is not concerned with the oxidation of glutamate to α-ketoglutarate, but with the further oxidation of the α-ketoglutarate. This is shown by the fact that the α-ketoglutarate (μmoles) found in the presence of phosphate was less than 1 per cent of the oxygen uptake (μatoms). Malonate (0·02 *M*) inhibited by 70 per cent the rate of oxygen uptake with liver mitochondria. The requirement for inorganic phosphate for maximal rates of oxygen uptake is explained by the fact that dinitrophenol cannot replace inorganic phosphate in the 'substrate-linked' phosphorylation step associated with α-ketoglutarate oxidation[3].

The rapidity with which the α-ketoglutarate formed from glutamate is oxidized by mitochondrial preparations was unexpected. It is clear that in the absence of an inhibitor of α-ketoglutarate oxidation, glutamate is not a suitable substrate for studying oxidative phosphorylation and respiratory control associated with the oxidation of reduced nicotinamide–adenine dinucleotides.

We wish to thank Prof. F. Lynen for a stimulating discussion which led us to examine more closely the products of oxidation of glutamate. This work was supported by a grant from the Netherlands Organization for National Health Research T.N.O. and the Koningin Wilhelmina Fund for Cancer Research.

PHARMACOLOGY

Histamine Sensitivity in Children after *Pertussis* Infection

IT has been shown in recent years that mice and rats are rendered hypersensitive to the action of histamine, 5-hydroxytryptamine and anaphylactic sensitization by pre-treatment with *Hæmophilus pertussis* vaccine[1-4]. These properties are present only in organisms in the smooth phase and are not shared by other members of the *Hæmophilus* family[5,6]. The sensitizing action is not seen in the guinea pig and the rabbit; on the other hand, there is some evidence that these two species are rendered slightly more resistant to histamine after such treatment[7]. Rats and mice are relatively resistant to histamine and anaphylactic shock, whereas guinea pigs and rabbits are susceptible. It was therefore of interest to study whether the reaction in man follows a similar pattern to the former two species or the latter. Recently there was an epidemic of whooping cough in Darbhanga and advantage was taken of this for such a study.

Histamine sensitivity was tested by the method developed by Jha in this laboratory. Briefly, it consists of placing on the fore-arm a lint soaked in an aqueous solution of histamine acid phosphate (10^{-5} conc. as base) and another in *N* saline. The anode of a 6-V. dry battery is placed on the histamine lint and the cathode on the other and current is allowed to pass for exactly 2 min. The reaction is read in 15 min. time. The normal reaction consists of erythema and occasional papules which never cover more than a quarter of the area of application, and is arbitrarily classified as (+). When papules cover half the area the reaction is read as (++) and when more than three-quarters are involved as (+++). A wheal formation is indicative of a marked hypersensitivity and is designated as (++++). By giving a score 2 to each (+), the average reaction can be expressed as a percentage of the maximal reaction possible. In this system of scoring, normal reaction is between 0 and 20 per cent, and values above 50 per cent represent hypersensitivity.

Sensitivity to 5-hydroxytryptamine, and the histamine liberator compound 48/80 can also be studied similarly.

Thirty children in the typical stage of 'whoop' in the age group 1–10 years were selected for the study, and the sensitivity to histamine, 5-hydroxytryptamine and compound 48/80 was determined separately. It was found that nearly all the patients were maximally sensitive to histamine (average reaction 88 per cent), and slightly sensitive to 5-hydroxytryptamine (average reaction 40 per cent). Wheals developed after histamine iontophoresis in majority of the patients, but were never encountered after 5-hydroxytryptamine. The patients failed to exhibit sensitivity to compound 48/80 (average reaction less than 10 per cent).

Thus it is seen that infection with *Hœmophilus pertussis* produces a condition in children similar to that noted in rats and mice. It is difficult to say at present whether such children are more susceptible to allergic reactions as well.

It has been reported that the anaphylactoid reaction (œdema) in rats is mediated through 5-hydroxytryptamine[8]. Such a conclusion may not be true for man, for although histamine in many cases produced an urticarial wheal, 5-hydroxytryptamine failed to do so when applied in a similar concentration. It may be noted that 5-hydroxytryptamine is 200 times as potent as histamine in producing the œdema reaction in the rat[9].

The fact that, even in patients maximally sensitive to histamine, compound 48/80 failed to produce significant reaction leads to the indirect inference that histamine content of the skin of children is low, particularly as when the experiments were repeated in adults, in many cases, typical reactions were obtained.

Interactions between Pharmacodynamic and Placebo Effects in Drug Evaluations in Man

IN the course of the development of a method sufficiently sensitive to evaluate the effects of small doses of tranquillizers in man, evidence of interactions between pharmacodynamic and placebo effects of drugs was adduced. Since placebo action (that is, the response to the act of taking medication as distinguished from the pharmacodynamic action of the medicament) must be taken into account in analysing human reactions to drugs, we feel that our findings have implications of general interest as well as of practical importance in designing methods for observing and evaluating the effects of drugs in man.

The influence of competitive mental work (a variant of the Stroop test[1]) on high-amplitude finger tremor and its modification by sedative drugs was studied in 12 male medical students. To control bias as well as placebo effects, dummy medication[2] in a capsule of identical appearance was administered in a classic double-blind arrangement[3]. To evaluate the extent of the placebo influence on the results, the test was also conducted with neither drug nor dummy. The tests were randomized.

The pertinent findings may be briefly summarized. After dummy medication had been given, the rate of high-amplitude finger tremor rose during the test from an average of 60 to 198 per min.; after 100 mgm. of pentobarbital sodium, it rose to 162; when neither drug nor dummy had been given, it rose to only 152 per min. By the sign test, statistical analysis indicated that each of the latter two is significantly smaller than the rate after the dummy capsule ($P < 0{\cdot}05$). However, the rate after 50 mgm. of pentobarbital did not differ significantly from that after the dummy.

Depending on the control used, the data may provide two diametrically opposed answers to the question of the effect of a sedative on high-amplitude tremor after competitive mental work. Thus, if the rate of tremor when neither drug nor dummy had been given is used as a control, 100 mgm. of pentobarbital is seen to have increased the tremor-rate. However, when the effect of 100 mgm. of pentobarbital is compared with the tremor-rate after a dummy, the drug appears to have decreased the tremor-rate. These results indicate that, with reference to the untreated, the drug made matters worse, whereas with reference to a placebo, the drug made matters better.

The increase in tremor-rate produced by 50 mgm. of pentobarbital is seen to fall within the range of the placebo effect. Consequently, the extent of the pharmacodynamic effect, if any, is uncertain. As a corollary, the placebo effect of the active agent is also uncertain, but it does confirm the stressful effect of the act of medicating.

The implications of these results are important for the clinical evaluation of drugs. The findings indicate that it is not always possible to anticipate the nature or the direction of placebo reaction in a particular circumstance. In this work, after it had been determined that the competitive mental work test did regularly and predictably increase the rate of high-amplitude finger tremor, it was presumed that the dummy would act as a placebo, that is, it would reduce the rate of high-amplitude finger tremor during the competitive mental work. However, it was found that the dummy medication intensified high-amplitude finger tremor and, as a result, tremor-rate after a sedative was also greater than when no treatment was given.

It is obvious from these trials that difficulty may arise in defining the base-line for the estimation of pharmacodynamic actions in man, hence in making absolute measurements of drug action. In this study, because drug and placebo effects were opposed, drug action could be measured in terms of the extent by which the drug diminished the placebo reaction. In the situation in which drug effect is in the same direction, but exceeds placebo effects, the question of how to obtain an absolute measure of drug effect is a difficult one, for the results may not indicate whether the drug action supplements placebo effect or accompanies it. In other cases, in which the subtraction indicates no effect in excess of placebo effect, it does not rule out the possibility of the complete masking of drug effect. This also brings up the question of the sensitivity of the method requisite for drug evaluations since, as the relative proportions of placebo and pharmacodynamic actions in the total effect change, the ability of a method to discriminate between them, hence its sensitivity, also changes[4].

It is of especial interest, therefore, that a so-called 'negative' placebo effect is not necessarily an obstacle to the development of a useful and sensitive method of drug evaluation, for if the nature and the direction of placebo reaction, hence the base-line, can be identified, drug effect can be measured accurately enough; indeed, sometimes more accurately when they are opposed than when the effect of one obscures the effect of the other, as it may, when they develop simultaneously and in the same direction.

In the present instance, the dummy induced, not a typical placebo effect but, instead, a significant and useful stress, and the competitive mental work test merely provided an additional challenge, while the pharmacodynamic effect opposed both. It can be assumed that, regardless of how well they were re-assured that there was no hazard, the use of volunteer medical students[5] who knew that they were participating in a drug investigation led to the unexpected and uniform placebo response. It is possible that, were the subjects entirely unaware of participation in an investigation and, more specifically, of drug testing, both placebo and pharmacodynamic actions might have been in the same, instead of opposite, directions. However this may be, this circumstance may nevertheless provide a well-controlled, sensitized setting for the evaluation of the small doses of tranquillizers so commonly used in general practice.

The importance of 'negative' placebo effects in simulating toxic effects of drugs has been stressed in the literature[6]. In the present case, such an effect has been measured and has been shown to be regular and predictable. Because of the several varieties of placebo reactions as well as their potential for interaction with pharmacodynamic effects of drugs[7], this dynamic quality, which is inseparable from the act of drug administration in man, must be taken into account, and controls must be used which identify the direction as well as the magnitude of placebo effects. For this it may be necessary to use the unblinded 'no-drug-at-all' control to complement the usual identical dummies in the double-blind setting.

This work was supported in part by the Mead-Johnson Fund and in part by the Clinical Pharmacology Fund of the Department of Pharmacology.

ANIMAL PHYSIOLOGY

Relation of Eye Dominance and Eye Closure

It is a well-known fact that while our vision is binocular, one eye (more often the right than the left) is in fact preferred or dominant in fixation and sighting. Much has been published on this subject, especially in its relation to handedness. We conjectured that if one eye is dominant in sighting, the other, that is, the non-dominant eye, would logically be expected to close more easily in order to enhance the use of the dominant eye, and as a corollary, the dominant eye would be more resistant to closure unilaterally because of the very nature of its dominance. In putting this theory to test, we used the students of our senior and junior anatomy classes (total 145, ranging from 18 to 24) as subjects. Eye dominance was first ascertained by three or more trials of the cone test in each case, and then the subjects were asked to close the right and left eyes singly and alternately for a number of times and to say which eye they found could close with less effort. This latter test was subjective; in some cases, however, we were able to see quite plainly for ourselves. The results of our investigation are given in Table 1.

Table 1

No. of subjects	Dominant eye	Ease in closing
63	*R*	*L*
31	*L*	*R*
29	*R*	*R*
16	*L*	*L*
4	*R*	*ND*
2	*L*	*ND*

L, Left eye; *R*, right eye; *ND*, no difference between the eyes.

The above results show that two-thirds of the subjects could close the non-dominant eye more easily than the dominant eye, while one-third the reverse. The value of chi-square obtained ($\chi^2 = 15\cdot527$ and $P = 0\cdot01$) shows a significant correlation between eye dominance and the relative ease of closure of the non-dominant eye. In addition, the results show that the differential function of the orbicularis oculi, innervated by the facial nerve, is a component in the dynamic complex of eye dominance.

Presence of Aldosterone-stimulating Hormone in Urine

THE secretion of aldosterone differs from that of other steroids of the adrenal cortex in that it is not directly under pituitary control. Current concepts favour a location in the diencephalon for the centre which controls aldosterone secretion[1]. The transmission of the stimulus from the centre to the effector gland cannot be nervous, since the isolated gland can respond to suitable provocations by an increased secretion of aldosterone[2]. It is therefore concluded that the stimulus is humoral.

Evidence for the presence in the urine of adrenalectomized rats deprived of sodium of a substance which modifies the secretion of an electrolyte-active steroid when injected into intact rats has been presented by Orti *et al.*[3]. This substance may be the hypothetical hormone responsible for the stimulation of aldosterone synthesis or release. The present investigation confirms the presence of this substance in urine under certain conditions, and evidence is presented that it is an 'aldosterone-stimulating hormone'.

Rats of Wistar strain, weighing about 150 gm., were bilaterally adrenalectomized and maintained on rat cake, with 1 per cent sodium chloride solution to drink. Groups of 20 of these animals were deprived of food and drink for 36 hr., and their urine collected over the last 12 hr. of this period. This urine was injected subcutaneously into groups of 5 intact rats, together with a sodium load of 1 ml. of 0·45 per cent sodium chloride solution per 50 gm. body-weight, administered intraperitoneally. 5 intact rats served as controls, receiving a similar sodium load intraperitoneally and a volume of urine from adrenalectomized rats receiving 1 per cent saline was given subcutaneously, equal in volume to that of the urine injected into the experimental group. Urine was collected individually from the 10 rats at intervals of 40 and 80 min. after the injection of the urine. Cross-over tests were made three days later. Statistical analysis of variance shows that the administration of urine from the salt-deprived animals resulted in a lowering of the sodium/potassium ratio in the urine of the intact animals compared with the control group, as shown in Table 1.

Table 1

No. of rats	Time (min.)	Mean sodium/potassium, experimental	Mean sodium/potassium, control	*P*
40	40	1·71	2·34	0·005
40	80	1·09	1·37	0·01

The urine from the experimental and control groups was collected in separate pools. This urine was hydrolysed for 48 hr., extracted with chloroform and run on the chromatographic system of Zaffaroni *et al.*[4] (toluene–propyleneglycol), or the '*B5*' system of Bush[5]. Insufficient material was present for a definite chemical identification of aldosterone to be made. The material running in the position of aldosterone was eluted from paper and bio-assayed in adrenalectomized rats. The urine from the experimental group possessed sodium-retaining activity.

Serial assay on a similar pool of urine showed that the substance was stable at 4° C. for seven days. It would also withstand boiling for 5 min. with little loss of activity.

These observations substantiate the presence in the urine of dehydrated adrenalectomized rats of a substance which, when injected into intact rats, causes a lowering of urinary sodium/potassium ratio, and circumstantial evidence is presented that this is due to the release of aldosterone. Corticotrophin, 1 U.S.P. unit per rat, did not possess this activity. It is concluded that the substance responsible for this effect is 'aldosterone-stimulating hormone'.

Biological Effects of Aromatic Extracts from Urine of Schizophrenics

Wada and Gibson[1] have recently reported that aromatic material extracted from the urine of schizophrenic patients induces behavioural and electroencephalographic abnormalities when injected intracisternally and intraventricularly in cats and monkeys. They used the fraction extracted by eluting with phenol-saturated water the material adsorbed on activated charcoal, according to the method of McGeer *et al.*[2].

Similar observations were made in the course of a series of experiments including the study of biological effects produced in mice, rabbits and dogs by aromatic fractions extracted from the urines of normal and schizophrenic subjects. The extracts were obtained by Decker's method[3], which is based upon elution with a water–methanol–butanol–ammonia mixture of the material adsorbed on activated charcoal. Of the group of substances thus extracted only the methanol-soluble fraction was investigated. Previous paper chromatographic analysis[4] of this fraction has shown that a larger number of aromatic substances is present in the urine of schizophrenic subjects.

The biological studies of such extracts included the determination of (*a*) the acute toxicity following intraperitoneal injection in mice; (*b*) the chronic toxicity in mice with histological examination of the brain and other viscera; (*c*) the behavioural effects following intracerebral injections in the rabbit; (*d*) the effect on the electrical activity of the cerebral cortex following topical applications in rabbits and dogs.

Both the aromatic fraction extracted from the urine of schizophrenic subjects and that from urine of normals have toxic properties. However, the fraction from schizophrenic patients appears to possess a higher acute toxicity and produces at lower dose-levels, upon chronic administration, degenerative changes of nerve cells of brain-stem nuclei. Furthermore, the aromatic urinary fraction from schizophrenic subjects has definite convulsant properties but only when brought into direct contact with the central nervous system. Intracerebral injections of minute amounts of the diluted extracts are readily followed by prolonged and generalized convulsions.

Direct applications of the diluted material to very small areas (2 sq. mm.) of the surface of the cerebral cortex cause localized convulsive alterations of the electrocorticogram.

Proximo-Distal Movement along the Axon of Protein synthesized in the Perikaryon of Regenerating Neurons

DURING regeneration of crushed nerve-fibres of spinal ganglion cells, the turnover rate of proteins in the ganglia (*C*.7 and *C*.8) increases extensively, as compared with the controls[1]. This finding, on one hand, justifies the increase in protein in the perikaryon of the regenerating neuron[1,2]; on the other hand, it supports Weiss's opinion[3] that some of the new proteins leave the body-cell and reach the growing end of the axon.

Movement of the protein along the axon can be studied by tagged compounds[4,5], especially when a set experimental condition is followed; that is, *in vivo* only the perikaryon of regenerating nerve cells must synthesize labelled proteins from tagged precursors (for example, *C*14-amino-acids). Thus, if the 'new' proteins move along the axon, it should be possible to collect them at the regenerating end of the nerve fibre. It is clear that a labelled precursor of proteins in the blood would contaminate all boundaries of crushed neurons, giving rise to difficulties in the evaluation of the phenomenon.

Hypoglossal and vagus nerves of adult rabbits were exposed on one side and crushed by forceps cooled to $-70°$ C.; the former at the level of the intermediate tendon of the digastric muscle; the latter at the carotid sinus. After 13 days, an opening was made on the middle nuchal line and a small window ($\sim$ 3 mm. diam.) was made through the atlo-occipital membrane. After removing the tela chorioidea of the fourth ventricle and drying the cerebrospinal fluid by filter paper, when necessary, the calamus scriptorius becomes clearly visible. About 0·001 ml. of Krebs and Henseleit solution[6], containing 0·2 gm. per cent of glucose, 5·55 mgm. per cent of L-threonine-^{14}C (*S.A.*, 32·9 μc./mgm.) and 7·8 mgm. per cent of L-valine-^{14}C (*S.A.*, 68·5 μc./mgm.), was placed on the calamus, using a micrometer syringe; the procedure was repeated every 20 min. for 5 hr. In this way it was possible to concentrate the tagged amino-acids in the region of the hypoglossal nucleus and dorsal nucleus of the vagus, without introducing significant quantities of carbon-14 compounds into the blood or cerebrospinal fluid.

At different intervals after the experiment, the growing segments of the XII and X nerves, as well as the homologous segments of the other side, used as controls, were removed. Each tissue sample was homogenized in 9 vol. of 5 per cent cold trichloracetic acid and the suspension centrifuged; the procedure was repeated twice and the residue was washed successively three times with acetone and three times with ether. Finally, the dry residue was hydrolysed in 1 ml. of 6 *N* hydrochloric acid in a sealed tube at 115° C. for 18 hr. The hydrolysate was brought to dryness at 50° C. in air stream, taken up in water and transferred to a planchet for determination of radioactivity in a gas-flow counter.

The results can be summarized as follows: (1) During the first 30 hr. after commencement of the experiment, the regenerating segments of the XII and X nerves showed no radioactivity. (2) In the next 10 hr., the regenerating segments displayed a significant amount of radioactivity. This radioactivity was inseparable from threonine and valine, as was demonstrated by autoradiograms of the amino-acids from the protein hydrolysate separated by paper chromatography. The control segments did not show any radioactivity. (3) Between the fortieth and seventy-second hour, radioactivity was still present within the regenerating segments; no radioactivity was found in the homologous normal segments.

A detailed account of the experiments will be published elsewhere.

Hæmostatic Mechanisms in the Animal Arterial Wall

DEPOSITION of fibrin on the interior surfaces of arteries after intimal injury forms the basis of the thrombogenic theory of the pathogenesis of arteriosclerosis[1]. Such fibrin deposits, covered by endothelium, have repeatedly been observed[2–6].

Fibrin deposition in the organism is determined by a hæmostatic balance between fibrin formation and fibrin resolution, which is regulated by the mechanisms of blood coagulation and fibrinolysis[7,8]. In order to try to substantiate the role of fibrin deposition as a primary process in the development of arteriosclerotic lesions, we studied the thromboplastic and fibrinolytic activities of the separated layers of the wall of the human aorta. We found high thromboplastic activity in the central layers (intima and media) and less activity in the adventitia. Little or no fibrinolytic activity was present in intima or media, while adventitia was highly fibrinolytic[9]. These results were verified by additional studies comprising samples of aortæ with varying degrees of atheromatosis[10]. The high thromboplastic activity of the human aorta (including intima) was recently confirmed[11].

It has proved difficult, if not impossible, to produce experimentally in animals pathological changes identical with human arteriosclerotic lesions. This observed fact has never been satisfactorily explained.

However, an investigation of the fibrinolytic activity of samples of aortæ from monkeys demonstrated considerable activity in intima and media[10]. Furthermore, in bovine aorta low thromboplastic activity was found in the intima, while media and adventitia had higher activity[12]. Hence, animal arteries apparently differ from human vessels in their hæmostatic systems.

In order to elucidate this problem we have recently compared the aortic walls in some animal species. The procedures were the same as applied in our previous studies[10]. Freshly drawn citrated rabbit plasma served as test substrate for the thromboplastic activity. The concentration of plasminogen activator in the tissue was estimated after extraction with 2 *M* potassium thiocyanate[13]. The results of this investigation are summarized in Table 1.

Table 1. ANIMAL SPECIES ARRANGED ACCORDING TO HÆMOSTATIC SYSTEM IN ARTERIAL INTIMA

Fibrinolytic activity in decreasing order; thromboplastic activity in increasing order. The results represent average values

Fibrinolytic activity

Animal	Adv.	M.		I.
Monkey	+ + +	+		+

Rabbit	(0)	+ +		+ + +

Adv., adventitia; M., media; I., intima; Inhib., inhibition.

It is apparent that great variations in the hæmostatic systems in different animal species exist. It is interesting to note that the rabbit, a preferred animal for experiments on connective tissue and vascular lesions, is low in fibrinolytic activity and high in thromboplastic activity, indicating an increased tendency to form and retain deposits of fibrin. The rat, on the other hand, has a coagulation inhibiting mechanism in its arteries. In this connexion it is of interest to recall that heparin and mucopolysaccharides with anticoagulant activity have been isolated from arteries of some species[14-16]. Apparently regulation of fibrin deposition can be obtained by several means depending upon the species in question. It is also of interest that high fibrinolytic activity (in man) is predominantly related to the venous system[17].

In none of the species investigated does the hæmostatic system compare exactly with that in the human organism. Based on our previous studies[9,10] the fibrinolytic system in human arteries appears similar to that in the pig, while the thromboplastic system is more active than in the rabbit. This means that the tendency to form fibrin deposits is more pronounced in man than in the rabbit, at the same time as there is little ability to produce resolution by means of a local fibrinolytic activity in the tissue. This finding suggests that resolution of fibrin deposits in the arterial system in man depends primarily on the activity of the humoral system in the circulating blood, which in man is characterized by a higher latent activity than in most animals. On the basis of these observations we offer the suggestion that the lack of a suitable experimental animal in studies of human arteriosclerotic lesions is due to differences in the hæmostatic systems of their arteries and in the circulating blood.

The results of this work will be published in detail elsewhere. Grants were received from the Josiah Macy, Jr., Foundation, New York, and from the National Danish Association against Rheumatic Diseases.

Effect of Cations on γ-Aminobutyric Acid Level in Slices of Brain Cortex

SINCE the discovery by Roberts and Frankel[1] of the unusually high content of γ-aminobutyric acid in brain, other mammalian tissues containing only minute amounts, a number of reports have appeared concerning the significance of this amino-acid to the physiological activity of the central nervous system[2].

The present communication deals with the effect of the concentration of potassium and calcium ions in the incubation media on the content of γ-aminobutyric acid in the slices. It is not without interest to examine the dependence of the amount of physiologically active γ-aminobutyric acid on the concentration of the ions K^+ and Ca^{2+} in the medium, as the importance of environmental ionic composition for the nervous tissue metabolism is known[3,4].

Guinea pigs were used as experimental animals; in individual experiments six groups of slices from four animals were prepared and the amount of the amino-acid in the tissue plus incubating medium after incubation in various salines was compared. Slices were incubated aerobically at 37° for 4 hr. in normal and modified Krebs–Ringer saline, the incubation stopped by denaturing the proteins, and the free amino-acids present in the supernatant after centrifugation of the homogenized slices separated chromatographically in a mixture of *n*-butanol/formic acid/water (75 : 15 : 10). Practically the same results were obtained with a 2-hr. incubation. The estimation of γ-aminobutyric acid in the corresponding strips of the chromatogram was carried out according to Yemm and Cocking[5].

It was found that, as compared with the control, only the intensity of the γ-aminobutyric acid spot on the chromatogram was markedly changed on

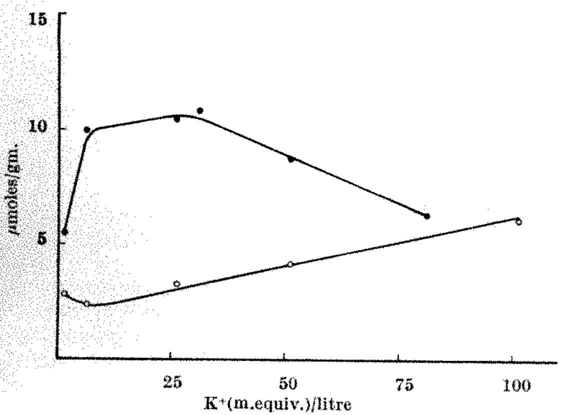

Fig. 1. Effect of K⁺ ions on free γ-aminobutyric acid and glutamine level in slices of brain cortex. The amounts of γ-aminobutyric acid (empty circles) and glutamine (full circles), estimated in the incubation media plus saline, expressed in μmoles/gm. fresh weight

incubation in a medium containing 25 m.equiv. K⁺/l. This observation was subjected to further analysis. As follows from Fig. 1, the γ-aminobutyric acid level is lowest during incubation in a medium containing 6·25 m.equiv. K⁺/l. With raised K⁺ concentration the amount of the amino-acid increases linearly and at 100 m.equiv. K⁺/l. it reaches the value of 6·2 μmoles/gm. fresh tissue. Also, the lowered potassium concentration causes an increase in the amino-acid level. The average amount of the amino-acid present in fresh slices was 2·9 μmoles/gm.

It is well known that γ-aminobutyric acid is formed by decarboxylation of glutamic acid. In another set of experiments under the same experimental conditions changes in the content of a different amino-acid, also arising metabolically from glutamic acid —namely glutamine—were followed. The amide was estimated from the amount of ammonia released on hydrolysis with trichloracetic acid, as described by Harris[6]. The decrease in glutamine formation, representing an endergonic reaction, with increasing amount of potassium in the incubation media is not surprising, the impairment of energy metabolism by potassium concentrations having been already repeatedly reported[3]. It appears (cf. Fig. 1) that no direct correlation exists between the γ-aminobutyric acid and glutamine levels in the slices.

Elliott and Florey[7] pointed out that a fraction of γ-aminobutyric acid is found in the brain tissue in a thermolabile 'bound' form hitherto not exactly defined. The question arose whether the increase in the γ-aminobutyric acid content was not partly due to the release of the acid from this labile form; therefore the amount of γ-aminobutyric acid was compared in boiled and unboiled homogenates after incubation in various media. It was found in preliminary experiments that the amount of this amino-acid was higher in the boiled homogenates after incubation of slices in the media with 1·25 and 6·25 m.equiv. K⁺/l. After incubation of brain tissue at higher concentrations of potassium the amount of the acid was nearly the same in boiled and in unboiled homogenates. It appears that the release of γ-aminobutyric acid from the thermolabile bond could be considered as a factor contributing to the increase in the level of the free amino-acid at higher concentrations of potassium in the saline. Furthermore, the possible activation of the glutamic acid decarboxylase under the experimental conditions described should also be taken into account.

On omitting calcium ions from the incubation medium the amount of γ-aminobutyric acid is increased, which is in agreement with the already well-established antagonistic action of calcium and potassium ions on brain cortex metabolism.

Details of this work will be published elsewhere.

Attempted Extraction of Crustacean Moulting Hormone from Isolated Y-Organs

Echalier[1,2] has shown, by extirpation and implantation experiments, that the *Y*-organs of Crustacea[3] produce the moulting hormone. The *Y*-organs are therefore physiologically (and morphologically) homologous to the prothoracic glands of insects. It has also been demonstrated[4,5] that extracts from whole Crustaea (*Crangon vulgaris*[6], *Emerita talpodia*, *Libinia* spp.[7]) are active in insects, initiating puparium formation in ligated *Calliphora* larvæ. Thus, they have the same action as ecdysone, the moulting hormone or prothoracic gland hormone of insects.

We have been interested in learning whether the arthropod moulting hormones are stored in the glands of internal secretion, or if they are produced there and then released into the blood. Excision of prothoracic glands of insects would be extremely difficult; in contrast, the anatomy of the crustacean *Y*-organ allows preparation of the glandular tissue for chemical investigations.

100 *Y*-organs were dissected from green crabs (*Carcinus maenas*) of about 75-mm. carapace width, in stage C_4 (that is, the intermoult period) of the moulting cycle, and preserved in methyl alcohol. 36 carcasses were also stored. The glands were then homogenized in methanol, centrifuged and re-extracted with methanol. The methanolic extracts were combined, evaporated to a small volume, diluted with water and extracted first with ethyl ether, then with butanol; the butanol solution was taken to dryness, yielding 12·5 mgm. extract.

The carcasses were homogenized in a Waring blendor and extracted with methanol. The methanolic extracts (approx. 3 l.) were combined, concentrated to a small volume, and, after dilution with water, extracted first with ether, then with butanol; the butanol solutions were washed with 0·2 *N* sulphuric acid, 2 *N* sodium carbonate, water, 1 *N* acetic acid, and water, and evaporated to dryness. The residue (5·12 gm.) was dissolved in butanol, adsorbed on 50 gm. alumina (activity *V* according to Brockmann) and eluted with 200 ml. butanol (fract. 1), 200 ml.

Table 1

Starting material	Total final extract (mgm.)	Amount injected (μgm.)	Puparium formation (per cent)	*Calliphora* units (ref. 8)
100 *Y*-organs	12·5	250	0	<10
36 Carcasses without *Y*-organs	Fract. 1 127	50	58	2,500
	Fracts. 2–3 913	50	33	9,000

butanol (fract. 2) and 500 ml. butanol–methanol 1 : 1 (fract. 3). Fract. 1 (2·1 gm.) was dissolved in ether, then extracted with water, and the aqueous layer extracted with butanol. The yield, after evaporation of the solvent, was 127 mgm. Fracts. 2 and 3 were combined (1·15 gm.) and treated in the same way: yield, 913 mgm. The purified extracts were bioassayed in *Calliphora* larvæ (cf. ref. 8) (Table 1).

From the result of the bioassay, it is obvious that the *Y*-organs do not store measurable quantities of the hormone: 100 glands contain less than 10 *Calliphora* units, while 36 carcasses contain more than 10,000 units. These results were obtained using intermoult crabs; it remains to be seen whether the same relation holds for pre-moult crabs, and for insects. In the latter case, however, removal of prothoracic glands is not feasible because of their diffuse nature.

The positive response of *Calliphora* to *Carcinus* extracts demonstrates once more the interchangeability of insect and crustacean moulting hormones. There is little doubt that the *Calliphora* assay is reliable in this respect, though confirmation by assay in other insects, for example, *Rhodnius*[9] or *Cecropia*[10], might be desirable. The chemical properties of the crustacean hormone differ from the insect hormone: the former is more strongly adsorbed to alumina.

Another insect gland, the corpus allatum, which produces the juvenile hormone, contains undetectable amounts of active material. The juvenile hormone is either rapidly destroyed[11] or excreted[12] or piled up in the abdominal tissue[13]. Apparently, the endocrine glands of arthropods do not function as storage organs.

PLANT PHYSIOLOGY

Gravimorphism and Root Formation

IT has previously been reported[1,2] that gravity can affect the growth and flowering of trees. The results to be described indicate that gravity may also affect the growth of some herbaceous plants in that the orientation of the shoot can determine whether or not root initials are formed in the stem.

Pot-grown plants of *Bryophyllum daigremontianum* (R. Hamet et Perv.) Berg. and tomato var. 'Moneymaker' were placed so that the shoots and the pots were horizontal. Staking ensured that the shoots remained horizontal within practical limits. One group of horizontal plants had the same side uppermost throughout, while a second group was placed on a horizontal klinostat which rotated the plants approximately once an hour. Preliminary experiments showed that rotating the plants through 180° once or twice each day did not prevent the formation of adventitious roots. A third group of plants was maintained with the stems and pots vertical. To facilitate watering, all the horizontal plants were placed erect for a short period each day.

After a few weeks of such treatments, adventitious roots were clearly visible on the underside of the stem internodes of those plants that were maintained with the same side uppermost. In *B. daigremontianum* these adventitious roots were visible after 2–3 weeks and continued to increase in size and number during the ensuing weeks (Fig. 1). At the end of the experiment many of the roots exceeded 2·0 cm. in length. Root formation in tomato was slower, taking 4–5 weeks to become visible. Under the conditions of the experiment tomato roots did not extend, although the lower side of the stems became covered with numerous root primordia. In both species roots were confined to the lower side of the horizontal stems. The rotated and vertical plants did not exhibit any abnormal propensity to form roots. Table 1 summarizes the results of one experiment with *B. daigremontianum*. The undersides of the horizontally placed stems were shaded, and it is not known how much this differential illumination may have affected the results[3,4]. This will be investigated and reported on in due course.

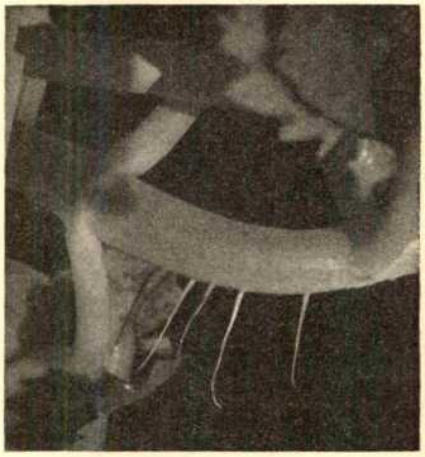

Fig. 1. Adventitious roots arising from a horizontally placed stem of *Bryophyllum daigremontianum*

Table 1. THE EFFECT OF GRAVITY ON THE ADVENTITIOUS ROOT FORMATION OF *Bryophyllum daigremontianum*

Stem position	Duration of experiment	No. of plants	No. of visible adventitious roots
Horizontal, rotated	37 days	6	2
Horizontal, non-rotated		6	72
Vertical		6	0

Loeb[5] observed that ". . . in *Bryophyllum calycinum* the substances which induce root formation have a tendency to collect on the lower side of a horizontally placed stem although roots may also appear in the nodes on the upper side. . . ." All the roots in Loeb's drawing were of nodal origin and not predominately internodal as in the present experiments. Resende[6], working with *B. daigremontianum*, noted that roots formed on the stems of horizontally placed plants at the point where the stems curved as a result of geotropic action. Both authors appear to have been recording manifestations of gravimorphism similar to those already described.

These observations are of horticultural significance in relation to the practice of layering used for the propagation of difficult subjects. Further, the rapid response of *B. daigremontianum* presents a ready means of demonstrating one of the effects of gravimorphism to students.

A more detailed account of this work will be published elsewhere.

Fungitoxicity of Metal Ions

IN a recent communication, Somers[1] has again considered the hypothesis first proposed by Mathews[2], that the toxicity of metal ions is related to the electrode potential of the metal. He has plotted the negative logarithms of the *ED*50 values of the applied molar concentrations of 21 elements for conidia of *Alternaria tenuis* against the electronegativity of the elements. An examination of the curve indicates clearly a correlation between the electronegativity and toxicity in the data presented. This is especially fortified by the low electronegativity of magnesium, strontium, lithium, sodium, barium and potassium ions which are basically not toxic to fungus conidia. If, however, attention is confined to that part of the curve which deals with ions toxic to fungus conidia (ions as toxic and more toxic than zinc), it is apparent that in a number of instances, the *ED*50 values are several orders of magnitude higher or lower than if they fell on the line drawn. As a matter of fact, examination of the data for these 15 elements, by calculating the rank correlation coefficient (calculated by Dr. F. Wilcoxon, Boyce Thompson Institute), shows that there is no significant correlation between electronegativity and toxicity in the area in which the toxic elements are found.

It should be pointed out that much information has been accumulated in recent years showing that the concentration of the applied solution is a poor measure of toxicity[3-9]. Fungus conidia have a great affinity for toxic ions and compounds as a result of which they often will take up lethal doses from dilute solutions in a minute or less. The applied concentration is thus maintained for a short time only and is important, not as such, but because it determines the dose available per unit of fungus conidia. Two toxicants may give equal *LD*50 values on an applied concentration basis but yet differ a hundredfold or more in innate toxicity. This follows because the germination response is determined by the quantity of toxicant taken up by the conidia with little regard to how such uptake was brought about. This is true for most of the toxicants studied, although there are exceptions. With zinc and cadmium the toxic effects are influenced by the length of exposure to the toxicant solution even when similar amounts are taken up[7].

Obviously the amount of a given ion taken up by conidia depends upon the quantities of binding sites in the spores and their availability to the ions presented in the ambient solution. The resultant toxicity would be determined by the essential nature of the binding sites occupied, and reversibility would be possible if the bond between the toxicant and the binding sites can be broken without impairment of essential functions. It is apparent, as also brought out by Somers[1], that chemical reactions occur between the applied ions and cell constituents. Such reactions can occur after the conidia are no longer capable of germination and thus can account for uptake of toxicants by spores no longer viable[4].

The question arises as to where these reactions between binding sites and the applied ions occur. Somers[1], in common with some others, believes that they occur at the cell surface. This point of view results from a belief that the conidia are permeable with difficulty to ions and compounds supplied and, moreover, it assumes that enough of the essential processes of the cell takes place at the surface, so that reaction at the surface can destroy germinative capacity. Experiments conducted at the Boyce Thompson Institute over the past ten years with labelled ions and compounds and labelled cell constituents have shown that a much freer movement of materials takes place across the membranes involved than was previously supposed. If fungus spores are collected without immersion in water and are then suspended in water, from 10 to more than 30 per cent of the cell constituents is released into the ambient solution[10]. The remaining contents are more firmly held, but further release will take place, without impairment of germination, on exposure to low doses of certain potentially toxic agents such as silver. Silver has been found to affect the conidia in such a way as to bring about a release of phosphorus compounds, as determined with spores labelled with phosphorus-32 [6,7]. Effects of silver on permeability are also shown by its action in increasing the uptake of other ions supplied, such as mercury and cerium[5].

Sonic disintegration of spores previously treated with relatively low doses of silver, mercury, cadmium, zinc, or cerium, and determination of the distribution of the labelled ions in various fractions isolated have not indicated an accumulation of these elements at the cell surface[11]. While there is a possibility of some redistribution taking place during the disintegration process, experiments indicate that very little redistribution actually occurs.

When conidia of different species are compared the quantity of toxicant that can be taken up is found to vary greatly from species to species. A species taking up very large amounts of one toxicant will not necessarily take up comparatively large amounts of a second toxicant. Also the ion may not be very toxic to a species which has a great affinity for it.

Experiments being carried out with cerium have shown that with some species the binding sites for cerium are readily available to cerium supplied in the ambient solution. With others the addition of 'Tergitol-7' (sodium heptadecyl sulphate) or CN^-, in non-toxic quantities, makes available further binding sites and thereby increases cerium uptake. The total potential cerium uptake, of course, also varies greatly among the species studied.

Ion interference studies now being conducted indicate that the interaction between conidia and the metal ions is much more complex than can be explained by differences in electronegativity. Thus cerium would not be expected to compete with silver or mercury for the same receptor sites, yet small amounts of cerium seriously interfere with the uptake of silver and mercury.

The evidence strongly indicates that much more than cell surface reactions is involved in the toxicity of metal ions to conidia.

Unpublished results referred to above will be reported in detail elsewhere. These investigations were supported in part by the United States Atomic Energy Commission and the Rockefeller Foundation.

Hydrogenation of Chloroplast Lipids by Rumen Bacteria

It was reported in an earlier paper[1] that rumen protozoa can hydrogenate unsaturated lipids. The suggestion was made that rumen bacteria may not contribute a great deal to hydrogenation of dietary lipids ingested by ruminants. This latter conclusion was based on experiments using washed suspensions of rumen bacteria, incubated anaerobically in phosphate buffer containing sodium sulphide, with either linseed oil, or linoleic or linolenic acids. Formic acid, glucose or finely divided plant material were also added in these experiments. Estimation of the iodine numbers of the total fatty acids in the samples showed either no change or only a slight decrease in the iodine values.

Since these results were considered rather unexpected, the role of the bacteria in hydrogenation has been reappraised using chloroplasts as a source of unsaturated lipid substrate. Rumen liquor was obtained from a rumen-fistulated cow routinely fed on fresh red clover (*Trifolium pratense*), care being taken to maintain both the temperature of the sample and anaerobic conditions. Washed suspensions of the bacteria were prepared by a method similar to that described by Doetsch, Shaw, McNeill and Jurtshuk[2]. The suspension was divided into two equal portions, one of which was placed in hot water (90°) for 30 min. to destroy enzyme activity. Equal aliquots of a chloroplast suspension[1] together with glucose (0·25 gm./100 ml.) were added to both samples and the flasks incubated overnight at 39° under carbon dioxide.

A second similar experiment was carried out using strained rumen liquor from which the protozoa and plant material had been removed by centrifugation (1,000*g* for 5 min.). Chloroplasts and glucose were added to the suspensions, one of which had been heated as above, and the flasks incubated overnight at 39° under carbon dioxide.

The samples were freeze-dried and the lipids extracted by boiling successively with acetone, absolute ethanol and diethyl ether. The solutions were evaporated to dryness, taken up in petroleum ether and the solvent removed *in vacuo*. The fatty acids from the lipids were isolated by the usual procedures[1] and their methyl esters analysed by gas-liquid chromatography.

Table 1. CARBON-18 FATTY ACID COMPOSITION OF CHLOROPLAST LIPIDS INCUBATED WITH RUMEN BACTERIA

Sample + chloroplasts + glucose (0·25 per cent w/v)	Suspending medium	Fatty acids (moles per cent)			
		Saturated	Unsaturated		
			mono-	di-	tri-ene
Live bacteria	*M*/15 phosphate buffer (*p*H 7·0) + 0·02 per cent $Na_2S.9H_2O$	4·1	11·0	7·6	77·3
Heated bacteria		4·0	4·0	10·0	82·0
	Difference	+0·1	+7·0	−2·4	−4·7
Live bacteria	Rumen liquor *p*H 7·0	9·4	24·1	62·2	4·3
Heated bacteria		5·0	6·5	5·0	83·5
	Difference	+4·4	+17·6	+57·2	−79·2

The results (Table 1) show a great contrast in hydrogenation activity between the bacteria suspended in phosphate buffer and those in rumen liquor. The bacteria incubated in phosphate buffer have caused only a slight, although definite, hydrogenation of the unsaturated fatty acids contained in the chloroplasts. There has been some conversion of triene to diene and monoene acids in the live bacteria sample. The bacteria suspended in rumen liquor have converted nearly all the triene acid to more saturated acids, particularly the diene acids. It is interesting that there is a build-up of the diene acids as this corresponds to the results found with rumen protozoa when it was suggested that the enzymes responsible for hydrogenation showed some specificity and attacked the triene acids more than the diene acids.

The low degree of hydrogenation in the washed suspensions is presumably the result of either harmful effects caused in the handling and preparing of these suspensions or the presence of some factor in rumen fluid that facilitates hydrogenation and explains the previous conclusions regarding the role of bacteria in ruminant hydrogenation. However, these results show there can be no doubt that rumen bacteria are capable of extensive hydrogenation, and emphasize the caution needed in the interpretation of results obtained under conditions far removed from those found *in vivo*.

I wish to thank Miss J. Michael for her able assistance and the Fats Research Laboratory, Wellington, for the gas–liquid chromatography analyses.

HÆMATOLOGY

Red Cell Agglutination by Stromal Material in Hæmolysates

During the preparation of hæmoglobin solutions a phenomenon was observed which, so far as is known, has not previously been described. The red cells of some species of animals are agglutinated by hæmolysates made from the cells of the same species. The degree of agglutination is sufficiently strong to be easily visible to the naked eye when tested on a slide.

Hæmolysates were prepared from the cells of a number of different animals by subjecting a 20 per cent suspension of washed cells to ultrasonic vibration. After centrifuging for 20 min. at 3,000 rev./min. to remove the larger particles of stroma, it was tested against washed cells of the various species. The results are shown in Table 1, where the degree of agglutination is recorded, following the usual practice of blood transfusion work[1]. From Table 1 it can be seen that the agglutination seems to be a property of the hæmolysate rather than of the intact cell; and that it is confined to the three rodent species.

Table 1

Cells of	Hæmolysates of cells of: Sheep	Rabbit	Dog	Horse	Rat	Guinea pig
Sheep	0	+	0	0	0	+
Rabbit	0	+++	0	0	++++	++
Dog	0	0	0	0	+	++
Horse	0	++++	0	0	0	0
Rat	0	+	0	0	+++	+
Guinea pig	0	0	0	0	+	+

Group *A* and *O* human cells were not agglutinated by any hæmolysate and hæmolysates of human cells of groups *A* and *O* caused no agglutination of cells of any species.

If packed washed rabbit cells are frozen and thawed with the minimum of disturbance a jelly-like material with the consistency of egg-white is produced. This material, which is probably stromatin[2], can be filtered off and washed. The filtered hæmoglobin, although very concentrated, produces no agglutination of intact red cells. On the other hand, the washed residue, although not entirely free of hæmoglobin, is very active in producing agglutination when dissolved in saline. This property can be removed by absorption with rabbit cells but is unaffected by treatment with fat solvents.

The properties of the hæmolysates are dependent on the method of preparation. Fresh washed rabbit cells were lysed: (1) by ultrasonic vibration; (2) by the addition of distilled water followed by the calculated quantity of 10 per cent saline to make the solution isotonic and (3) by freezing. The hæmolysates were handled with care to avoid shaking. On completion of lysis all three preparations produced a similar degree of agglutination. After centrifuging at 96,000*g* for 1 hr. it was found that the supernatant fluids varied considerably in their ability to agglutinate washed cells. The deposit was re-suspended in saline by shaking vigorously for at least 5 min. before centrifuging at 3,000 rev./min. for ½ hr. The results of testing the supernatant fluid and the deposit against whole cells are summarized in Table 2.

Table 2

Method of production of hæmolysate	Hæmolysate: Deposit	Supernatant
1. Ultrasonic vibration	+	+++
2. Distilled water	+++	+
3. Freezing	+++	0

The probable explanation of these findings is that the more violent method of disruption of the cells also disintegrates the red cell envelope and stroma, some product of which is added to the solution and not removed by high-speed centrifugation for 1 hr. The gentler methods, however, leave this substance attached to the 'cell ghosts' which are found in the deposit.

We can conclude, therefore, that the agglutination of homologous and some heterologous red cells by hæmolysates of rabbit, rat and guinea pig red cells is due to a substance liberated from the stroma. The amount of this substance in the solution is determined by the method of lysis and the amount of shaking during preparation. This variation in composition may explain the divergent results obtained by the earlier workers in experimental hæmoglobinuric nephrosis.

Asymmetrical Recombination of Alkali-dissociated Hæmoglobin Mixtures

The human adult hæmoglobins and canine hæmoglobin recombine asymmetrically, that is:

$$\alpha_2^X\beta_2^X + \alpha_2^Y\beta_2^Y = \alpha_2^X\beta_2^Y + a_2^Y\beta_2^X$$

after both short and prolonged exposure to dilute acid[1-5]. At *p*H 11, hæmoglobin *A* dissociates into half-molecules[6]; furthermore, re-association of a mixture of labelled hæmoglobin *S* and hæmoglobin *A* after 24 hr. at *p*H 11 results in the exchange of the β_2 sub-units[7]. We now wish to report a series of experiments which indicate that hæmoglobin also recombines asymmetrically after short exposure to alkali.

In the first experiment a 2 per cent carbonmonoxyhæmoglobin solution (all carbonmonoxyhæmoglobin

Fig. 2. Ascending-limb electrophoretic patterns of 1 per cent. carbomonoxyhæmoglobin in phosphate buffer of pH 6·3, Γ/2 0·02. The direction of migration is from right to left. (*a*) *S,A,I*, control; (*b*) *S,A,I*, recombined after 20 min. dissociation at pH 11·2; (*c*) *S,A,I*, recombined after 20 min. dissociation at pH 4·7. Note the new component between *A* and *I* in (*b*) and (*c*)

solutions were electrodialysed prior to use), 1 per cent in canine hæmoglobin and 1 per cent in human hæmoglobin, was diluted to 1 per cent by adding an equal volume of a glycine–sodium hydroxide buffer of pH 11·0, Γ/2 0·2. The solution was dialysed against this same buffer at Γ/2 0·1 for 24 hr. at 5° C. followed by dialysis against three changes of potassium phosphate buffer of pH 6·8, Γ/2 0·02 for approximately 17 hr. Upon electrophoresis in the same phosphate buffer two new components appeared, one migrating more slowly than canine and the other migrating more rapidly than *A*, as was the case after exposure to dilute acid (Fig. 1). 20-min. exposure to the same glycine–sodium hydroxide buffer produced only very small amounts of the new components. It was found, however, that the addition of the hæmoglobin mixture to the glycine–sodium hydroxide buffer changed the pH to 10·5 and therefore further experiments were carried out with glycine–sodium hydroxide buffers of a higher pH. A buffer of pH 11·5, Γ/2 0·2, when added to an equal volume of 2 per cent carbonmonoxyhæmoglobin, resulted in a pH of 11·0, and a buffer of 11·8 resulted in a final mixture pH of 11·2. After 20-min. exposure, the amounts of the new components observed upon electrophoresis at pH 6·8 were found to increase with increase in the dissociation pH. In one experiment in which the pH 11·8 buffer was used, immediate neutralization to pH 6·9 was effected after 20 min. by the addition of sodium dihydrogen phosphate. In all the others, 20-min. exposure to alkali was followed by dialysis in the potassium phosphate buffer pH 6·8. These results are shown in Table 1 and Fig. 1. Human and canine carbonmonoxyhæmoglobin, when dissociated separately at pH 11·0 for 20 min. and re-associated, showed no change in electrophoretic composition. Dissociation and recombination did not alter the absorption spectrum (450–700 mμ) of any of the samples.

Table 1. COMPOSITION OF CANINE AND HUMAN HÆMOGLOBIN MIXTURES BEFORE AND AFTER RECOMBINATION

Dissociation (pH)	Dissociation (time)	Electrophoretic composition (per cent of total)*			
		New slow	Canine	*A*	New fast
Control	—	—	37	63†	—
10·5	20 min.	2–3	39	55	4
11·0	20 min.	5	37	51	7
11·2	20 min.	11	35	41	13
11·2	20 min.‡	12	36	42	10
11·0	24 hr.	25	26	20	29
4·7	20 min.	10	36	44	10
4·7	22 hr.	31	24	21	24

* All samples contained 50 per cent each of human and canine hæmoglobin before recombination.

† Includes 2 per cent A_2.

‡ Followed by rapid neutralization to pH 6·9 by addition of sodium dihydrogen phosphate.

A 50–50 mixture of carbonmonoxyhæmoglobins *A* and *I* (the sample contained 40 per cent *A* and 60 per cent *I*) and carbonmonoxyhæmoglobin *S* was dissociated at pH 11·2 for 20 min., neutralized rapidly to pH 6·9 by the addition of sodium dihydrogen phosphate and dialysed against three changes of potassium phosphate buffer of pH 6·3, Γ/2 0·02 for about 18 hr. Moving-boundary electrophoresis in the same buffer showed a new component migrating between *A* and *I*, a decrease in the proportions of *S* and *I* and increase in the proportion of *A*. The dissociation and recombination of *A* and *I* alone produced no change in the electrophoretic pattern. The results are given in Table 2 and Fig. 2.

Table 2. COMPOSITION OF *A*, *I* AND *S* HÆMOGLOBIN MIXTURES BEFORE AND AFTER RECOMBINATION

Mixture	Dissociation (pH)	Dissociation (time)	Electrophoretic composition (per cent of total)			
			I	New	*A*	*S*
$A + I$	Control	—	54	—	46	—
$A + I$	11·2	20 min.	56	—	44	—
$A + I + S$*	Control	—	30	—	17†	53
$A + I + S$	11·2	20 min.‡	25	7	18	50
$A + I + S$	4·7	20 min.§	29	4	18	49

* All $A + I + S$ samples contained 50 per cent hæmoglobin *S* and 50 per cent $A - I$ hæmoglobin mixture, the latter containing 40 per cent *A* and 60 per cent *I*.

† Includes 1 per cent of trailing shoulder.

‡ Followed by rapid neutralization to pH 6·9 by addition of sodium dihydrogen phosphate.

§ Followed by rapid neutralization to pH 6·4 by addition of disodium hydrogen phosphate.

An attempt to perform similar experiments with human hæmoglobin *A* using the 'hæm-labelling method'[2] was unsuccessful, due to the rapid denaturation of methæmoglobin at pH 11 and above.

The appearance of two new electrophoretic components after alkalinization and neutralization of a mixture of human hæmoglobin *A* and canine hæmoglobin parallels the findings after exposure to dilute acid. The net change can be represented by the equation:

$$\alpha_2{}^{A}\beta_2{}^{A} + \alpha_2{}^{\mathrm{can}}\beta_2{}^{\mathrm{can}} = \alpha_2{}^{\mathrm{can}}\beta_2{}^{A} + \alpha_2{}^{A}\beta_2{}^{\mathrm{can}}$$

Similarly, the appearance of a new component between *A* and *I* and an increase in the proportion of *A* after alkali dissociation and neutral re-association of a mixture of hæmoglobins *A* and *I* and hæmoglobin *S* parallels the findings after acidification. The net change in this case can be represented by the equation:

$$[\alpha_2{}^{I}\beta_2{}^{A}]^{-4} + [\alpha_2{}^{A}\beta_2{}^{S}]^{+2} = [\alpha_2{}^{I}\beta_2{}^{S}]^{-2} + [\alpha_2{}^{A}\beta_2{}^{A}]^{0}$$

It would appear that the mode of recombination of a mixture of hæmoglobins after exposure to dilute alkali is the same as that following exposure to dilute acid, that is, asymmetric.

Although at equilibrium carbonmonoxyhæmoglobin *A* is completely dissociated at *p*H 11 and but partially dissociated at *p*H 4·7 (ref. 6), our results show that the amount of asymmetric recombination is the same after 20 min. at either *p*H. Complete recombination occurs in either case after 22–24 hr. The extent to which partial recombination occurs after a short period of dissociation thus appears to reflect more closely the rate of exchange of sub-units rather than the equilibrium degree of dissociation.

Acidification of hæmoglobin results in asymmetric dissociation into α_2 and β_2 sub-units[2]. Asymmetric dissociation in alkali would provide the simplest mechanism compatible with our present results. If, as proposed by Vinograd and Hutchinson[8], hæmoglobin dissociates symmetrically into the half-molecule $\alpha\beta$ in alkali, the mechanism of recombination in alkali must be more complex than in acid.

We are indebted to Dr. L. M. Tocantins for the sample of *A–I* hæmoglobin.

PATHOLOGY

Plasma Erythropoietin in Polycythæmia Secondary to Renal Disease

An increasing body of experimental work indicates an intimate relationship between the kidney and the plasma erythropoietin-level[1-4]. It has long been recognized that in man there is a frequent association between chronic renal disease and anæmia, and it has been demonstrated that the plasma erythropoietin-level is reduced in chronic renal failure[5]. More recently, the association of certain other renal pathological conditions (for example, carcinoma of the kidney and hydronephrosis) with polycythæmia has been recognized[6,7]. However, studies on the plasma erythropoietin-level do not appear to have been reported in polycythæmia secondary to renal disease.

This communication is a preliminary report of studies on two such cases (to be reported more fully at a later date).

The two patients were middle-aged men in whom the diagnosis of polycythæmia was confirmed by red cell volume studies using chromium-51. The renal lesions were unilateral hydronephorosis in case I and a unilateral polycystic kidney in case II. In both cases, nephrectomy was performed, and the studies were repeated approximately four months after operation, at which time they were no longer polycythæmic.

Table 1

		Hb (gm. per cent)	P.C.V. (per cent)	Reticulocytosis in rats 72 hr. after injection of plasma (per cent)
Case I	Preoperative	18·3	55·0	5·7 6·1 Mean = 5·9
	16 weeks after operation	14·6	44·5	3·4 3·3 Mean = 3·4
Case II	Preoperative	18·7	55·0	8·9 8·4 Mean = 8·7
	19 weeks after operation	15·2	47·5	3·0 3·3 Mean = 3·2
Pooled plasma from five normal subjects		—	—	3·3 3·2 Mean = 3·3

Plasma samples were obtained pre-operatively and approximately four months post-operatively. The erythropoietin content of these samples was assessed by measuring the reticulocytosis induced, in black hooded rats, 72 hr. after a 2 ml. intraperitoneal injection of plasma. The results are given in Table 1.

These two cases appear to demonstrate convincingly the association of certain renal lesions with polycythæmia and increased plasma erythropoietin-levels, and show that a return to the normal erythropoietic state follows removal of the pathological kidney.

We wish to express our thanks to Dr. J. L. Pinniger for helpful advice and for permission to publish this communication.

Identification of a Bovine Mucosal-Disease Virus isolated in Sweden as *Myxovirus parainfluenzae 3*

'Bovine mucosal disease' is the collective name proposed for different syndromes characterized mainly by inflammatory changes in the mucosa of the gastro-intestinal or respiratory tracts, or both, of cattle. The ætiology was uncertain in spite of successful transmission experiments. By the use of tissue culture for virus isolation, what are apparently different viruses have been found associated with such syndromes, but only one of these, the virus of infectious bovine rhinotracheitis, has hitherto been investigated thoroughly.

Quite recently, Reisinger *et al.*[1] in the United States reported the isolation of a myxovirus from cases of shipping fever, a respiratory disease in cattle. Abinanti and Huebner[2] found this virus, called *SF*–4, to be serologically identical to the prototype strain of *Myxovirus para-influenzae* 3 (ref. 3), called *HA*–1, which was first isolated by Chanock *et al.*[4] from cases of respiratory disease in children.

A contagious form of enteritis in cattle, which seemed to be a variant of the mucosal disease type, has been described from Sweden[5]. The clinical signs have varied from outbreak to outbreak; the gastro-intestinal signs may dominate in one outbreak and respiratory signs in another. Differences in clinical signs were also observed within herds and during an outbreak[6].

Bakos *et al.*[7] investigated cases of a bovine mucosal-type disease with mainly respiratory symptoms and a severe course at Umeå in northern Sweden during 1958–59. The disease seemed to be introduced by cattle purchased from other parts of the country. The first signs of the disease were serous conjunctivitis and rhinitis, often combined with excessive salivation, high fever and, in some animals, diarrhœa. Then the nasal discharge became muco-purulent, the salivation more intensive and buccal erosions sometimes appeared; coughing was common. In some instances watery diarrhœa was the only sign encountered. The malignant course led in one of the infected herds of losses of up to 70 per cent of animals by inanition and dehydration. A cytopathogenic agent was isolated in calf kidney tissue cultures from nasal and tracheal exudates of the animals in two of the nine herds investigated. This agent was neutralized by convalescent sera from animals in these herds. It passed 'Gradocol' membranes with an average pore diameter of 240 mμ but not 130 mμ. In calves free of neutralizing serum antibodies, the agent produced in experimental infection a mild form of mucosal disease of the same type seen on the farms.

At titration of this so-called Umeå-strain of virus in calf kidney tissue cultures, it showed only slight cytopathogenicity but was more cytopathogenic when inoculated at higher dilutions. Therefore the subsequent passages were carried out in two lines, one with undiluted inocula and the other diluted 10^{-2} before inoculation. The former has been carried for 23 passages and the latter for 33 passages. The viruses have been designated strain 23 and 33 respectively. Both strains showed hæmagglutinins against guinea pig and chicken erythrocytes and strong hæmadsorption of guinea pig erythrocytes to the tissues in the infected tubes. Of the strains 23 and 33, only the latter produced clear plaques.

The strains 23, 33 and Chanock's[4] strain *HA*–1 of para-influenza 3 virus[3] have been compared by titration in calf and monkey kidney tissue cultures using lactalbumin-Hanks' solution (0·5/99·5 per cent) as maintenance medium. The hæmadsorption and hæmadsorption-inhibition tests were performed according to Chanock's modification[4] of the method described by Shelokov *et al.*[8], and the hæmagglutination, hæmagglutination-inhibition, and neutralization tests according to the standard techniques. In *HI* tests, the Umeå serum has been used untreated, and treated with *RDE* (cholera filtrate, Philips-Roxane, Holland). No difference could be observed in the antibody titres between the treated and untreated samples. In some of the experiments the *HA*-2 strain[4] of para-influenza 1 virus[3] and a serum against this strain were used for comparison.

The strain 23 showed slight or questionable cytopathogenicity for calf kidney cells only, and lower titres of infectivity for calf and monkey kidney cells than the strains 33 and *HA*–1. The strain 33 was definitely cytopathogenic for calf kidney cells and the strain *HA*–1 for monkey kidney cells, both showing approximately the same titres of infectivity. In neutralization tests monkey kidney cells were used for the strain *HA* 1 and calf kidney cells for the strain 33.

The results of cross-neutralization tests, summarized in Table 1, indicate a close relationship between the Umeå virus and the *HA* 1 strain of para-influenza 3 virus.

Table 1. EVIDENCE FOR THE SEROLOGICAL RELATIONSHIP BETWEEN THE VIRIS UMEÅ AND THE STRAIN *HA* 1 OF PARA-INFLUENZA 3 VIRUS

HISTOLOGY

Preparation of Ultra-Thin Sections of Mineralized Human Enamel

THE preparation of ultra-thin sections of hard substances for electron microscopy without preliminary softening presents special difficulties. The use of industrial diamonds fashioned into knives suitable for cutting hard materials was first described by Fernández-Morán[1]. These knives, prepared with a cutting bevel of approximately 50–52°, can be used to cut or cleave thin sections of bone or tooth dentine. The sectioning of hard brittle materials, however, increases the risk of damaging the knife edge from glancing blows, since diamond is itself extremely brittle. The smallest natural cleavage angle obtainable from a diamond depends on the angles formed by the natural crystal planes (this angle is in the region of 70°), consequently in order to construct a diamond knife with the greatest possible edge strength, the two faces of the knife should form this angle. Two diamond knives both with the cutting faces diverging from the knife edge at an angle of 70° were prepared for us several years ago in the Johannesburg research laboratory of the Industrial Distributors, Ltd., under the

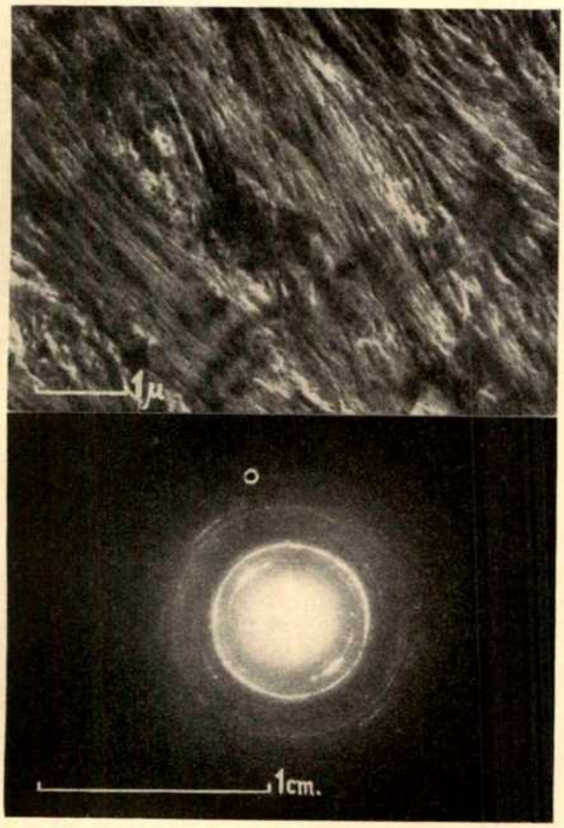

Fig. 1. Above, electron micrograph of fully mineralized unembedded human tooth enamel ; below, selected area electron diffraction pattern from 1a. The pattern is characteristic of orientated apatite crystals. Kv. 100, pole piece 2, diffraction aperture 30 μ. Instrument constant $K = 1{\cdot}93$

direction of Dr. J. F. H. Custers and the late Dr. Paul Grodzinski.

These knives have now been under test for approximately five years without repolishing, and have successfully cut human tooth enamel without detectable damage to the edge. Fully mineralized human enamel is much harder than bone or dentine and has approximately the same degree of hardness as topaz. According to Gustafson and Kling[2] the Vickers micro-hardness number of enamel varies from 300 to 400 kgm./mm.^{2}. The Vickers micro-hardness value obtained from the specimen illustrated in this communication was 412 kgm./mm.^{2}. Because tooth enamel is extremely brittle, unsupported sections disintegrate when they come into contact with the collecting fluid. They may be collected, however, by first coating the surface to be cut with a thin film of 0·2 per cent 'Formvar' dissolved in chloroform. The surface is further supported by pressing a small piece of 'Sellotape' on to the surface to be cut. By holding the 'Sellotape' the section can be removed from the upper surface of the knife at the end of the cutting stroke. The specimen is then pressed face down on to a glass slide in a drop of 'Formvar'. When dry, the 'Sellotape' can be removed by dissolving the adhesive in petroleum ether.

Thick sections mounted in this way are suitable for phase-contrast microscopy. Alternatively, after removal from the knife the section may be floated 'Sellotape' side down in petroleum ether. When the adhesive dissolves, the 'Sellotape' backing sinks leaving the section supported by 'Formvar' floating; this may then be collected on an electron microscope grid. An example of an electron micrograph and an electron diffraction pattern obtained from a section of human enamel prepared in this way is shown in Fig. 1. It is possible that this technique might be usefully applied to other brittle substances.

The preparations were examined with a Siemens Elmiskop 1 electron microscope, generously provided by the Wellcome Trust. The work was further assisted by a grant from the Medical Research Council.

RADIOBIOLOGY

Chelating Agents in the Treatment of Poisoning by Polymerizable Radioelements

The rate of reaction between a chelating agent and a hydrolysable polyvalent metal ion such as thorium (IV) is dependent on the degree of polymerization of the metal ion. It would be anticipated, therefore, that the degree to which a chelating agent might enhance the excretion rate of certain radioelements from the body would be variable even though factors such as dose and route of administration were kept constant. Accordingly, we investigated the effect of a strong chelating agent on the excretion of thorium-234 which was injected intravenously into rats in two different forms—a monomeric, diffusible form and a polymeric or colloidal form. The chelating agent used was diethylenetriaminepentaacetic acid, which forms an exceptionally strong chelate with thorium[1] (the 1 : 1 chelate has a $\log K = > 27$).

A chemical demonstration of the difference in reactivity of the two forms of thorium toward the same chelating agent is easily given. For example, when a solution of thorium nitrate ($p\text{H} = 2{\cdot}5$) is mixed with excess diethylenetriaminepentaacetic acid and the pH of the solution is increased to 7 with sodium hydroxide, the resulting solution remains clear because of the formation of the stable thorium–diethylenetriaminepentaacetic acid chelate. However, if an identical solution of thorium nitrate is neutralized before the diethylenetriaminepentaacetic acid is added, a precipitate forms which does not dissolve upon the addition of diethylenetriaminepentaacetic acid. Prolonged contact between the thorium precipitate—presumably an inorganic hydroxylated polymer[2]—and diethylenetriaminepentaacetic acid causes a slow dissolution of the precipitate over a period of many days.

In the metabolic experiments, two kinds of thorium solutions were used. The monomeric, or 'ionic', solution was prepared by adjusting a solution of carrier-free thorium-234 chloride with trisodium citrate and sodium hydroxide so that it contained 1 per cent citrate ion and had a final pH of 5·0. The polymeric solution was prepared with thorium-234 nitrate and stable thorium nitrate, adjusted with sodium hydroxide to pH 2·5 and a concentration of 1 mgm./ml. as carrier thorium. (The total concen-

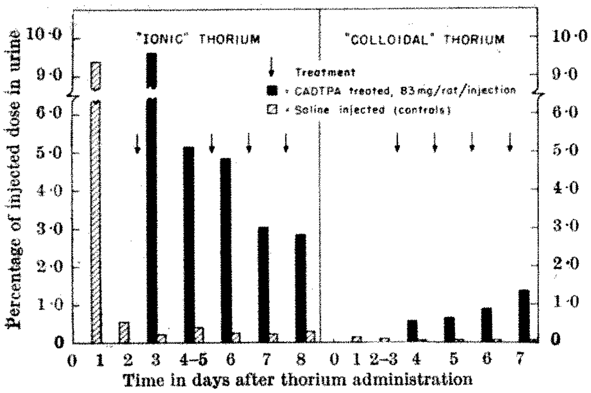

Fig. 1. Effect of diethylenetriaminepentaacetic acid (CADTPA) on the urinary excretion of thorium in rats

tration of thorium in this solution therefore was 2×10^7 times as high as in the ionic solution.) This solution gave a well-defined Tyndall beam without evidence of visible precipitation. Mature Sprague–Dawley female rats, three rats per group, injected intravenously with 0·5 ml. of one of the two solutions at a level of 0·6 μc. per rat, were placed in individual metabolism cages. Two or more days later, the treated groups received a series of four daily intraperitoneal injections of 300 mgm./kgm. of the calcium chelate of diethylenetriaminepentaacetic acid, and the controls an equivalent volume of saline. A 24-hr. urine sample was collected daily throughout the experiment for each rat. The animals were killed by cervical fracture 24 hr. after the last treatment injection. The soft tissues and femurs were wet-ashed and counted for beta activity using an end-window Geiger–Müller counter.

The results show that diethylenetriaminepentaacetic acid caused a marked reduction of the body burden of thorium only when thorium was administered in the monomeric, or 'ionic', form[3]. Under these conditions, the thorium was deposited mainly in the skeleton. The total urinary excretion of thorium for the treated groups was 34 per cent of the injected dose as compared with 12 per cent for the saline controls. The pattern of this excretion is shown in Fig. 1. The first injection of diethylenetriaminepentaacetic acid increased the 24-hr. excretion from a control level of 0·5 per cent to more than 9 per cent of the injected dose. Subsequent injections effected significant increases, but the absolute amounts which were removed steadily diminished with each injection.

The effect of diethylenetriaminepentaacetic acid treatment on rats to which thorium had been given in polymeric, or 'colloidal', form is in marked contrast to this. The total urinary excretion was only 3·6 per cent of the injected dose in the treated group as compared with 0·2 per cent in the saline controls. The thorium was deposited mainly in the liver. In addition, the pattern of the excretion is quite different, as is shown in Fig. 1. Each subsequent injection of diethylenetriaminepentaacetic acid increased the urinary excretion of colloidal thorium to a level higher than that obtained with the previous injection.

It is unlikely that these differences in the distribution and excretion of the two solutions of thorium are a function of the difference in their concentration. It has been shown that thorium is closely related to plutonium in its metabolism[4] and that the distribution and excretion of plutonium are independent of dose[5]. Rather, the results shown in Fig. 1 can be explained as follows: when 'ionic' thorium is injected it is prevented from polymerizing because of rapid complex formation with body proteins. The administration of diethylenetriaminepentaacetic acid readily removes the bound but monomeric thorium by the formation of a diffusible chelate. Each subsequent injection of diethylenetriaminepentaacetic acid removes the labile, available thorium, but the amount of thorium available for removal diminishes with each treatment. However, in the case of 'colloidal' thorium, an insoluble polymer is deposited in the tissues. In the presence of sustained levels of diethylenetriaminepentaacetic acid within the tissues[6] the particles of thorium become slowly depolymerized. Consequently the amount of labile thorium, that is, thorium–diethylenetriaminepentaacetic acid chelate, increases with time so that subsequent injections of chelating agent result in an increase of excretion over the previous injection.

Details of these and other metabolic experiments involving the removal of thorium with chelating agents will be published elsewhere. The results cited here emphasize the point that the success of the use of chelating agents in the treatment of radioelement poisoning is dependent on the chemical and physical properties of the radioelement.

This work was performed under the auspices of the U.S. Atomic Energy Commission. We are indebted to Miss Elizabeth Moretti for technical assistance.

Atmospheric Radiocarbon Activity in 1959

ATTENTION has already been directed to the appreciable rise in the atmospheric radiocarbon activity following the testing of nuclear weapons[1–4]. On the basis of data obtained up till 1958, Broecker and Walton[1] estimated a rise in the atmospheric radiocarbon concentration in the northern hemisphere of 5 per cent per annum, though Münnich and Vogel[2] had arrived at a rate of rise of 3·2 per cent per annum. Measurements made in the summer of 1959, however, indicate a general level of activity greatly in excess of what might have been expected from either of these estimations.

In an attempt to evaluate the progressive rise in concentration in Britain over the past seven years, samples of annual oat crops were kindly supplied by the National Institute of Agricultural Botany, Cambridge, from its seed collection, and assayed for radiocarbon in this Laboratory. Oats have a very short growing season, and photosynthesize principally at the time of year when Münnich and Vogel[5] have demonstrated that the seasonal intensity of radiocarbon has reached its maximum. This variation has been ascribed to the rise in the tropopause in

Table 1

Sample No.	Year of harvest	Change from 1953 (per cent)
Q–436	1953	0·0 ± 0·5
Q–437	1954	− 0·7 ± 0·5
Q–438	1955	+ 1·2 ± 0·5
Q–439	1956	+ 3·0 ± 0·5
Q–440	1957	+ 11·5 ± 0·6
Q–441	1958	+ 14·5 ± 0·6
Q–442	1959	+ 31·8 ± 0·7

summer, allowing part of the stratosphere to mix freely with the troposphere. The crops were grown in and around Cambridge, and thus the measurements from year to year are directly comparable.

If the level of activity of 1953, before any appreciable nuclear weapon testing had been carried out, is taken as the standard activity for subsequent years, the results (Table 1) may be expressed as a percentage variation from this value.

The large difference in activity between the summers of 1958 and 1959 must be attributed to the intense testing programmes undertaken late in 1958, and its delay in appearing in the atmosphere probably lies in the mechanism of the seasonal variation already referred to.

It is interesting to note that the activity of a sample of human neck hair cut in the late summer of 1959 was 16·5 per cent greater than the 1953 oat sample, and is thus considerably less than the activity of the 1959 oat crop. During the period of growth of this hair we can assume that the population was in the main still consuming the cereal and root crops of the previous season.

If the present suspension of nuclear weapon tests were to become permanent, the future level of the atmospheric radiocarbon activity, together with that of the surface ocean water, should furnish further valuable information about the exchange rates of carbon dioxide between the various phases of the radiocarbon reservoir[1,2].

BIOLOGY

Implantation of Tissue Transplants in the Uteri of Pseudopregnant Mice

It was thought that transplants of tumour into the uterine cavities of pseudopregnant mice might simulate the invasive properties of the embryonic trophoblast sufficiently to throw light on the uterine reactions involved in the implantation of the embryo. Since the initial results of these studies, which are still in progress, appear to show clearly that the site of implantation is determined by the uterus, a preliminary report may be justified.

Table 1. TUMOUR TRANSPLANTS IN PSEUDOPREGNANT LAB. GREY AND C57 BLACK MICE

* Animals in which only a few melanoma cells have invaded the mucosa.

Mature females of strains *C*57 Black (pure line) and Lab. Grey (stock) mated with vasectomized males were used. The day on which the vaginal plug was found was taken as day 0 in the pseudopregnant cycle. The tumour used was the Harding–Passey[1] melanoma. Laparotomies were performed under ether anæsthesia and the tissue fragment inserted into the uterine lumen with a Bashford implantation needle (bore 0·625 mm.), ligatures being placed around the uterus above and below the transplant, which otherwise was expelled either through the incision or the cervix. The tumour was invariably transplanted into the right uterine horn and usually a fragment of the animal's own body-wall muscle into the other horn. Transplantations were performed from days 0 to 9 and the animals killed 2 days later. The uteri were then removed, fixed in Zenker's fluid and sectioned transversely. No differences were observed between the *C*57 Black and the Lab. Grey strains.

It is apparent from Table 1 that implantation of the tumour in the uterine mucosa within the 2-day duration of the experiments was most frequent when the transplantation was effected on the fourth day of pseudopregnancy. Implantation was not observed after transplantation on days 0–2 or 7–9 of pseudopregnancy or during diœstrus. The autografts of muscle in the other uterine horn were made only

—*, Experiments where the tumour tissue did not become implanted, but the control muscle tissue did.

on days 3–6 of pseudopregnancy and failed to become implanted in only one instance in fifteen experiments.

The melanoma or muscle tissue when it became implanted did so invariably on the antimesometrial side of the lumen as does the normal embryo in the mouse. As a rule the tumour had penetrated the epithelium and deeply invaded the mucosa, the camera lucida outline diagram of a section in Fig. 1 being typical. The muscle tissue became attached to the mucosa, usually with destruction of the epithelium but without further invasion of the mucosa. The position and extent of the attachments are represented in Tables 2 and 3 by dividing the camera lucida outline drawings of the median transverse section into 6 sectors, as in Fig. 1, sector I being mesometrial and sector IV antimesometrial.

The tissue fragments implanted were many times larger than a normal embryo, being at least five times the diameter, yet whether homografts of melanoma or autografts of muscle were employed, implantation occurred with remarkable uniformity antimesometrially in precisely the region where an embryo would have become implanted. It is difficult to escape the conclusion that the antimesometrial site of implantation is determined by the uterus and that the properties of the mucosa at the appropriate stage of pseudopregnancy are such as to encourage the attachment of all these diverse tissues. The work of McLaren and Michie[2] has shown that the siting of implantations along the length of the uterus is not predetermined.

Other aspects of this work still in progress, such as the induction of the decidual reaction, together with a full report of the histological findings, will be published later.

I am indebted to Prof. F. W. R. Brambell for his advice and encouragement, to Prof. A. Haddow, of the Chester Beatty Institute, for supplying the tumour, and to the staff of this Department for technical assistance. The work was performed during the tenure of a Research Studentship of the Department of Scientific and Industrial Research.

Effect of Soil Drying on the Viability of *Heterodera major* Cysts

WINSLOW[1] has shown that dried cysts of *Heterodera major* do not hatch well. He found that more than two thousand larvæ hatched from cysts recovered from wet soil, whereas only seven larvæ hatched from cysts which had been recovered from dried soil. Hesling[2], in an experiment carried out at Rothamsted, confirmed Winslow's results, and concluded that this eelworm is quite sensitive to drying.

Cysts of *H. major* were found on the roots of volunteer oat plants which were growing in discarded infected soil. Prior to being discarded, this infected soil had been air-dried in the laboratory and, since cysts were found on the roots of oat plants growing in this soil later, it would appear that the drying of the soil did not seriously affect the viability of the cysts in it.

Early in January 1955, a quantity of infected soil was placed in a heap and was thoroughly mixed to ensure uniformity in cyst-distribution throughout. A microplot (in the field) was filled with this mixture and at certain intervals over a period of fifteen months a portion of soil, sufficiently big to fill ten test-tubes, was taken from the microplot and was air-dried. When the soil was dry, the ten test-tubes were filled with it, and it was thus stored in this air-dried condition in the laboratory until sowing time. This gave lots of infected soil which had been air-dried for periods of 1, 3, 6, 9, 12 and 15 months. Ten tubes containing infected soil which was not air-dried and ten tubes containing non-infected soil were included in the experiment, also, and were used as controls.

On April 16, 1956, all tubes were sown with oats (variety Sun II), and were plunged in a bed of peat-moss in the field.

By the middle of June, cysts of *Heterodera major* were found to be quite plentiful on the roots of plants growing in the infected soil which had been air-dried for periods of one and three months and in the infected soil which had not been air-dried. It must be emphasized that the soil, when dried for these periods, was 'dust-dry', and was certainly dry enough for cyst extraction using the Fenwick apparatus.

Despite repeated examinations, cysts were not observed on the roots of plants growing in infected soil which had been air-dried for periods of 6, 9, 12 and 15 months. It was concluded that, if infected soil is air-dried, and kept in an air-dried condition for a period of 6 months or longer, the cysts lose their viability and their contents become incapable of hatching and invading the roots of a host-plant.

It is interesting to record that the effect of drying on the viability of the cysts was reflected in the growth of the plants. The plants growing in soil which had been air-dried for periods of 6, 9, 12 and 15 months were comparable in size and vigour with plants which were growing in tubes of non-infected soil, and showed no symptoms of eelworm attack. On the other hand, plants growing in the infected soil which had been air-dried for periods of 1 and 3 months showed symptoms of severe eelworm attack and were very dwarfed and diseased-looking.

The hatching experiments of Winslow[1] and of Hesling[2] suggest that cysts of *H. major* are far more sensitive to drying than the above-mentioned observations made by me found them to be. It is possible that the effect of drying becomes more pronounced when the cysts are removed from the soil, a factor which might explain this apparent contradiction in results.

Albinism in *Cryptomys hottentotus* Lesson, 1826

In an earlier communication[1] I reported the occurrence of what appeared to be an albino specimen of the above species of mole-rat. I am grateful to Miss D. Watson for a further and similar example, collected on November 12, 1958, at a point within a few hundred yards of where the first animal was taken.

As in the previous instance the mammal was taken on the surface, and was examined while still alive. In all respects the coloration was similar to that previously described, except that the dietetic staining was not so pronounced. The specimen, an adult male, was preserved entire, and revealed the following body measurements: head and body, 130·0 mm.; tail, 15·0 mm.; hind foot s.u., 22·0 mm. The cheek teeth were again simple, 4/4.

Previously I stated that normal specimens of *C. hottentotus* at Inyanga possessed a "variable white head-spot which is sometimes vestigial". Since this was written I have handled specimens of adults, taken side-by-side with head-spotted examples, in which the head-spot has been entirely absent. Thus it seems that Inyanga specimens are the antithesis of those described by Roberts[2], who notes the position regarding head-spots as "white frontal spots are not infrequent, but abnormal". The converse may be said to be true at Inyanga.

It might be of further interest to note that while the tail normally has a length of about 11·0–22·0 per cent of head and body-length, some specimens may have tails as long as 30·0 per cent of head- and body-measurement.

Quantitative Immuno-Analysis in Gel Plates

I cannot let pass unchallenged certain assertions made by Wright[1] in his communication in *Nature* of May 2, 1959, with reference to my method for quantitative immuno-analysis in agar gel plates[2]. Dr. Wright states: "Although there are several methods available, none of them is easily applicable to a multi-antigenic system, and in addition the concentrations of the proteins can only be estimated separately, even under favourable conditions, at ±10 per cent and more usually ±50 per cent".

The entire joy of the quantitative plate method, as outlined in my original communication[2] and since extended[3-5], is that it permits the ready titration of multi-antigenic systems and the simultaneous assay of individual antigens, often on a single plate. It has the further advantage of not requiring titration to an end-point, assays being readily performed by comparison of precipitation patterns.

As for the sensitivity of the technique, claims below ±10 per cent have not been made simply because we have never felt the need for greater accuracy and have been content to use, at the narrowest, 1·1 × serial dilutions. A narrower dilution gradient, as used by Wright in his technique, could well produce accuracies better than ±10 per cent.

MICROBIOLOGY

Exogenous Respiration in *Nitrobacter*

During the course of an investigation of the oxidation of nitrite by the nitrite-oxidizing bacterium, *Nitrobacter*, it was noted that the addition of sodium nitrite but not sodium nitrate to heavy cell suspensions caused the immediate appearance of reduced cytochrome bands at 590, 551 and 513 mμ when viewed in the hand spectroscope[1]. This phenomenon, which has been noted previously by Lees and Simpson[2], is due to the passage of electrons through the respiratory chain when nitrite is oxidized to nitrate. Whether or not nitrifying bacteria respire in response to substrates other than their energy source has been disputed, although Bömeke[3] reported a slight stimulation of the respiration of *Nitrobacter* when certain metabolites were added to cell suspensions in the Warburg respirometer. If some reduced substance is oxidized by resting cells and if a cytochrome-linked pathway is employed for the oxidation of all substances which can permeate the cell, then any substance which might increase the rate of respiration in the Warburg respirometer should also cause a reduction of the cellular cytochromes. The validity of this rationale was tested in the following manner.

Cultures grown for 4–8 days at 25° C. on a reciprocating shaker in a mineral medium (gm./l.: sodium nitrite, 1·0; sodium chloride, 0·5; dihydrogen potassium phosphate, 0·44; dipotassium hydrogen phosphate, 2·88; crystalline magnesium sulphate heptahydrate, 0·3; ferrous sulphate, 0·003; sodium carbonate, 1·0; pH to 7·0–7·2) were harvested by centrifugation and washed until free of nitrite. Heavy cell 'creams' were thoroughly aerated for 30–60 min. and then observed in the Hartridge reversion spectroscope (slit-width 125μ). The spectrum obtained was that of an oxidized cytochrome system, and it remained oxidized for at least 30 min. after the cessation of aeration. Various substrates (0·1 ml. of neutralized 0·05 *M* solutions) were pipetted into the cell suspension and it was observed for 30 min. for spectral changes. As shown in Table 1, only sodium nitrite and formate caused a reduction of the cellular cytochromes. The bands appeared immediately (within 10 sec.) and were in identical positions for both substances.

Table 1. THE EFFECT OF SELECTED METABOLITES ON THE RESPIRATION OF *Nitrobacter*

Addition	Reduced cytochrome bands appearing, mμ	Q_{O_2} (28° C.)
None	None	2·4
Sodium nitrite	590, 551, 513	51·7*
Sodium nitrate ..	None	N.T.
Sodium formate ..	590, 551, 513	10·8*
Sodium acetate ..	None	4·8†
Sodium lactate ..	None	2·2
Glucose	None	1·8
Sodium citrate .	None	1·3

N.T. = Not tested.

* No lag.

† After 50-min. lag during which respiration was equivalent to endogenous.

The effect of these substances on the oxygen uptake of washed cells was tested by conventional techniques in the Warburg respirometer (final concentrations: substrate, 25 μ*M*; pH 7·2 phosphate buffer, 400 μ*M*; potassium hydroxide in the centre well). Oxygen uptake was followed for a total of 2 hr. after tipping in the substrate, although nitrite was completely oxidized within the first 45 min. It may be noted in Table 1 that of the substances tested, only formate and nitrite readily stimulated oxygen uptake. Thus formate is a metabolizable substrate for intact *Nitrobacter* cells. Whether the slight increase in oxygen uptake with acetate is significant is not known—however, it lies within the range of experimental error. Thus only those substances which evoked the rapid reduction of cellular cytochromes caused an increase in uptake of oxygen. The spectroscopic method, therefore, appears to offer a rapid and convenient way to survey potential substrates for *Nitrobacter*.

These preliminary results suggest that the following interesting speculations be tested: The autotroph, *Nitrobacter*, differs from better-known heterotrophic bacteria in that it is not permeable to many of the usual metabolic intermediates. This is reflected by the lack of effect of common metabolites on respiration. It is reasonable to postulate that many of the common enzyme systems are operative within the cell, but the use of intact cells gives no evidence of this potentiality due to the impermeability to the required substrate. Cell-free preparations, however, should possess many of the enzyme systems which catalyse the utilization of some of the substances listed in Table 1. These hypotheses are now being tested experimentally by spectroscopic and manometric techniques.

This work was aided by a grant from the Society of the Sigma Xi and a contract between the Office of Naval Research, Department of the Navy, and the University of Florida, No. 103–431 (Nonr–2651 (00)).

Shape of Ultra-violet Inactivation Curves of Transforming Deoxyribonucleic Acid

IN analysing the effects of radiation on biological systems, it is customary to plot the logarithm of the surviving fraction (or of the fraction of the biological activity remaining) against the applied dose. When such a plot gives a straight line passing through the origin, the radiation sensitivity of the system may be characterized by a single constant, which is conveniently taken as the negative slope of the logarithmic inactivation curve. Such a curve is consistent with the assumption that the inactivation results from independent, single events (inactivating 'hits') occurring at random[1].

When the inactivation of bacterial transforming deoxyribonucleic acid by ionizing or ultra-violet radiation is analysed by this procedure, the curves are not straight lines, but bend steadily in the direction of shallower slopes as the radiation dose increases[2-4]. 'Multicomponent' curves of this character require two or more constants for their characterization. They are obtained if the irradiated population is heterogeneous in its sensitivity to radiation[1], each class being inactivated according to a straight line curve (exponential law). In such cases the plot becomes a straight line at high doses where the survivors consist chiefly of members of the most resistant class. These curves can also result from suitable heterogeneity in the substructure of each individual. Deoxyribonucleic acid inactivation results for ionizing radiations have usually been interpreted in terms of one of these schemes, with attempts to determine the 'limiting slope' at high radiation doses corresponding to one resistant class of deoxyribonucleic acid molecules or one class of molecular substructures[5,6].

In semi-logarithmic inactivation curves for *Hemophilus influenzae* transforming deoxyribonucleic acid exposed to 254 mμ ultra-violet radiation, we find a steadily decreasing curvature at high doses[4], in agreement with other workers[3]. These inactivation curves, for all the genetic markers tested, can be converted into straight lines over a wide range of high doses by plotting the logarithm of the transforming activity against the *logarithm* of the ultra-violet dose (instead of against the ultra-violet dose itself) (unpublished work of S. H. G.). Such a relation on a log–log plot is incompatible with a straight line on a semi-log plot, and indicates a power-law inactivation at these doses rather than some variety of exponential law.

Preparation, ultra-violet inactivation and assay of transforming deoxyribonucleic acid were carried out as detailed in ref. 7 (except that the concentration of deoxyribonucleic acid in contact with bacterial

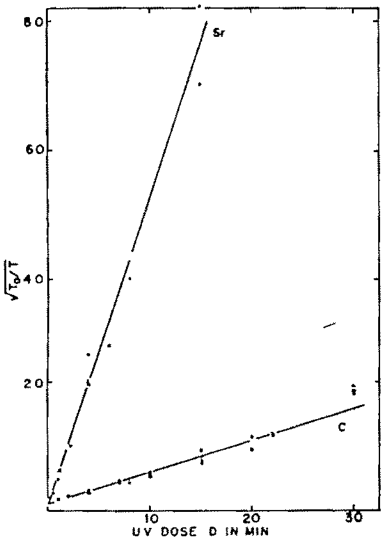

Fig. 1. Reciprocal square root of the fractional transforming activity $\sqrt{(T_0/T)}$ vs. the radiation dose D (in min. at 1.650 ergs mm.$^{-2}$ min.$^{-1}$ of 254 mμ radiation). T_0 is the transforming activity before irradiation, and T the activity afterwards of the genetic markers, streptomycin resistance (Sr 2 000 γ/ml.) and cathomycin resistance (C 2·5 γ/ml.). Deoxyribonucleic acid concentrations in contact with cells during transformation were as follows: (●) 5×10^{-3} γ/ml.; (○) 5×10^{-2} γ/ml.; (×) 10^{-1} γ/ml.

cells during transformation was as indicated in the caption of Fig. 1). The ultra-violet dose-rate in ergs/mm.^{2}/min. was estimated from the rate of inactivation of $T2$ bacteriophage[8]. For all markers tested, a plot of the reciprocal square root of the transforming activity against dose leads to straight lines over the entire dose-range (Fig. 1), implying an inverse square law:

$$T/T_0 = 1/(1+CD)^2 \qquad (1)$$

Here T_0 is the initial transforming activity of a preparation, T is the activity after exposure to a radiation dose D, and C is a constant depending on the particular genetic marker under study. This single constant, which may be used to characterize the sensitivity to radiation of the marker, is equal to minus one-half the initial slope of a semi-logarithmic plot of the same results. The entire curve may be used, however, in determining it, instead of only the initial portion. From the slopes of the lines in Fig. 1, the relative sensitivities to ultra-violet radiation of the streptomycin-resistance and cathomycin-resistance markers of *H. influenzae* are easily specified as being in the ratio of 10 to 1, a fact which would be difficult to state quantitatively from the usual presentation. Genetic markers for erythromycin resistance and viomycin resistance (which also give straight lines on an inverse square root plot) have sensitivities very close to that of the cathomycin marker.

The straight line region, of slope minus 2, which appears on a log–log plot at high doses, corresponds to the entire dose-range in which $CD \gg 1$; that is, to the region in which the transforming activity is less than about 10 per cent of that preceding irradiation.

The absoluteness with which relation (1) holds can be determined only by extensive experience. Experiments covering the low dose-range more thoroughly than those reported here show that it describes inactivation very well in this region. At the very highest doses it may perhaps predict a slower inactivation than is actually found by experiment, since the points shown for cathomycin resistance at 25 and 30 min. (41,000 and 50,000 ergs/mm.^{2}) lie slightly off the theoretical fitted curve. This discrepancy is not clearly present in all experiments and its reality is not certain.

At present we offer no theoretical interpretation of relation (1), which is entirely empirical. Its simplicity suggests that the complex ultra-violet inactivation curves observed on semi-logarithmic plots may, after all, arise from a relatively simple mechanism, although one which possibly differs from the type of inactivation envisioned by elementary target theory. The simpler and apparently more appropriate manner of presenting ultra-violet inactivation data which now becomes available should facilitate studies aimed at determining this mechanism.

This work was supported by Senior Research Fellowships *SF*-218 and *SF*-312 from the U.S. Public Health Service.

STATISTICS

Performance of a Stochastic Net

Stochastic nets have been proposed by several authors[1–3] as models of cognitive activity. So far, these have been dominated by heuristic constraints designed to show some analogy with the nervous system or merely for ease of computation. An adequate mathematical theory has, as was recognized by Uttley[4], to show how such a device can learn relations.

In the following I give a model which with a simple and natural constraint has the ability to detect linear relations and record their components in a principal axis frame of reference; as such it has obvious relations with well-known topics of linear analyses, namely, multiple factor[5], and prediction and filtering[6] theory.

Consider a collection of n cells i; let α_i, α^i, be their inputs and outputs respectively and W_{ij} the strength of connexion from cell j to i such that if α_i^S is the input from sensory field S to cell i, we have: $\alpha_i = \alpha_i^S + W_{ij}\,\alpha^j$ (summation over repeated indices), assuming unit linear amplification for each cell i (that is, $\alpha^j = \delta^{ji}\alpha_i$); the effective amplification with positive feedback W_{ii} is $(1-W_{ii})^{-1}$ so that the above can be written:

$$\alpha_i^S = (\delta_{ij} - W_{ij})\,\alpha^j = A_{ij}\alpha^j \text{ say} \qquad (1)$$

W_{ij}, α_i^S may be positive or negative according as their synaptic endings are excitatory or inhibitory.

Consider n outputs of receptors from a sensory field S such that the covariance:

$$C_{ij} = \lim_{T\to\infty} C_{ij}(T) = \lim_{T\to\infty}\frac{1}{T}\int_0^T \alpha_i^S(t)\,\alpha_j^S(t)\,\mathrm{d}t \qquad (2)$$

exists. The structure of this matrix reflects the simplest properties of the field S, namely, if the rank $r<n$ then there will be $n-r$ linear relations between the α_i^S. If now we can arrange that:

$$\lim_{t\to\infty}\ \sum_k A_{ik}(t)\,A_{jk}(t) = C_{ij} \qquad (3)$$

then we shall have a description of the field $S(t)$ in terms of n outputs $\alpha^j(t)$ which are orthonormal in the sense that:

$$\lim_{T\to\infty}\ \frac{1}{T}\int_0^T \alpha_i(t)\,\alpha_j(t)\,\mathrm{d}t = \delta_{ij} \qquad (4)$$

and of which therefore $n-r$ must be arbitrary, that is, generated by the net itself. Were it not for this, which will allow us to distinguish them from the r outputs representing $S(t)$, we should have gained nothing from the transformation (1).

To realize (3), let us put:

$$t\frac{\partial A}{\partial t}ik + \frac{1}{2}A_{ik} = \frac{1}{2}\alpha_i^S\alpha_k \qquad (5)$$

Multiplying through by A_{jk}, using the symmetry of C_{ij} and summing over k it is easy to show that this satisfies (2) and (3). However, (3) only determines A_{ij} up to an orthogonal transformation corresponding to an arbitrary rotation of the orthogonal frame; the additional condition:

$${}_k\Sigma\, A_{ki}A_{kj} = \lambda_i\,\delta_{ij} \qquad (6)$$

determines the principal axis solution, where λ_i are the proper values of C_{ij}. If (6) holds, then we have:

$$A_{ij}\,\alpha_i^S = \lambda_j\,\alpha_j \qquad (7)$$

multiplying (5) by A_{ij} and summing this time over i, one can check that (6) follows.

Using (1) and (4), the corresponding condition for the connexions is:

$$t\frac{\partial W}{\partial t}ij + \frac{1}{2}W_{ij} = \frac{1}{2}(\alpha_i - \alpha_i^S)\alpha_j \qquad (8)$$

which means that the (negative) connexion between two cells is proportional to the correlation between the activity of the cell from which the connexion is coming and the stimulus on the cell to which it is going. For the feedback of a cell to itself the same is true of the reciprocal gain. This shows that if α_j is uncorrelated with any of the α_i^S, then the cell j is effectively isolated and its gain rises to an infinite value such that α_j is a self-generated signal of unit variance. Under these conditions an indefinitely flat peak in the frequency response will produce a single-frequency sinusoidal output. If no two of these frequencies are exactly equal, then (4) will certainly be satisfied. It is not unreasonable to compare this behaviour with the α-rhythm of the inattentive brain. Furthermore, the principal axes solution in which the co-ordinate axes are determined by successive extrema of the stimulus vectors is the one most indicated by physiological evidence.

An example of the application of such a net would be the following: suppose we have n audio receptors responding to a frequency band $\Delta\nu_i$, and let their (rectified and smoothed) outputs be $\alpha_i^S(t)$. For a sensory field such as normal speech, the latter will be highly correlated, so that a smaller number r will be able to convey the information. In fact, just such a procedure has been used[7] in a speech communication channel known as the 'Vocoder'. For example, with $\Delta\nu_i = 15$ c./s., $n = 16$, we can have $r = 10$ without loss of fidelity.

However, the significance of the net as a model of local brain activity would appear to be the following. If we drop the rigour implied in the infinite limit of (2), then what the net does for us is to factorize a sensory field into a part which has no constancy in time and a part which is invariant over a period of time T, and which is expressed in the values of the A_{ij}. Over longer periods of time, the latter may vary and could be the subject of analysis by a net of longer time constant. In this way knowledge is possible in spite of the conditional and incomplete nature of all relations.

Note added in proof. To obtain the principal axis solution uniquely some modification of (5) is required; it will be given elsewhere.

Standardized t

Students' t may be standardized by expressing it in units of its own standard deviation; thus, $t_s = t\sqrt{\{(\nu-2)/\nu\}}$, where ν is the number of degrees of freedom. The procedure reduces the variability of the tails with ν for a given probability, P, and in particular, for $P = 0{\cdot}05$ and $\infty \geqslant \nu \geqslant 4$, t_s lies between 1·96 and 2·0 whereas t lies between 1·96 and 2·776. This finding extends the applicability of certain 'large' sample methods down to 4 degrees of freedom. The standardizing is extremely simple to apply—merely divide the error sum of squares by $\nu - 2$ instead of by ν and use this value to calculate the appropriate standard error (*SE*). For example, if d is the difference between two means and $d \geqslant 2\ SE$, $P \leqslant 0{\cdot}05$, that is, the difference is significant at the 5 per cent level. If $d < 1{\cdot}96\ SE$, $P > 0{\cdot}05$ and the difference is not significant. Between these two limits of d, $P \simeq 0{\cdot}05$; actually $0{\cdot}0535 > P > 0{\cdot}0455$. Again, $\pm 2\,SE$ will give a close approximation to 95 per cent confidence limits (actual value between 95 and 95·45 per cent). When the formula is applied to the correlation coefficient, r, we find that r is significant at the 5 per cent point if $r \geqslant 2/\sqrt{(\nu+2)}$.

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, February 22

Institution of Electrical Engineers (at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion on "Are We Making the Best Use of Research Resources" opened by Mr. L. Rotherham.

Institution of Mechanical Engineers, Education Group (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "The Place of Management Studies in the Training of an Engineer".

Monday, February 22—Friday, February 26

Engineering Materials and Design Exhibition and Conference (at Earls Court, London, S.W.5).*

Tuesday, February 23

University of London (at Queen Mary College, Mile End Road, London, E.1), at 1.30 p.m.—Dr. Donald Hunter: "Historical Perspective in Science and Medicine".

Institute of Marine Engineers (at the Memorial Building, 76 Mark Lane, London, E.C.3), at 5.30 p.m.—Mr. A. Bell: "Corrosion and Fires in Marine Boiler Air Preheaters".

Institute of Physics, Electronics Group (at 47 Belgrave Square, London, S.W.1), at 5.30 p.m.—Dr. W. M. Lomer: "Magnetic Properties of Alloys".

Institution of Chemical Engineers (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. H. E. Rose: "Vibratory Ball-mills".

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. W. R. S. Doll: "Epidemiological Methods in Leukæmia Research".* (Thirteenth of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation. Further lectures on February 25 and March 1.).

University of London (in the Chemistry Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. J. A. B. Gray: "The Place of Physiology in University Education".*

Institution of Electrical Engineers, Education Discussion Circle (at Savoy Place, London, W.C.2), at 6 p.m.—Discussion on "Courses for Electrical Technicians" opened by Prof. M. W. Humphrey Davies.

Institution of Mechanical Engineers, Lubrication Group (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "Water Lubrication".

British Interplanetary Society (joint meeting with the London Branch of the Institution of Plant Engineers, at the Royal Society of Arts, John Adam Street, Adelphi, London, W.C.2), at 7 p.m.—Mr. R. H. B. Forster and Mr. L. Breen: "Some Problems Encountered in the Design of Large Rocket Test Beds".

Royal Aeronautical Society (at 4 Hamilton Place, London, W.1), at 7 p.m.—Mr. A. J. Troughton: "Relationship between Theory and Practice in Structural Problems".

Society of Instrument Technology (at Manson House, 26 Portland Place, London, W.1), at 7 p.m.—Mr. D. F. White and Mr. L. E. Taylor: "Backscatter Method of Wall Thickness Measurement"; Mr. M. V. James: "Ultrasonic Resonance Method of Wall Thickness Measurement".

Wednesday, February 24

University of London (at the Postgraduate Medical School of London, Ducane Road, London, W.12), at 2 p.m.—Dr. R. R. Race: "The Genetics of Blood Groups".*

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m—Prof A. C. B. Lovell, F.R.S.: "The Exploration of Outer Space" (Trueman Wood Lecture).

Royal Statistical Society (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.15 p.m—Mr. E. Strauss: "The Structure of the English Milk Industry".

Institute of Fuel (at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 5.30 p.m.—Mr. E. H. Hubbard: "Comparison of Different Methods of Fluid-atomizing Oil Flames", and "The Effect on Flame Emissivity and Radiation of the Addition of Carbon Black to Liquid Fuels" (Performance Trial No. 8 of the Joint Committee of the International Flame Research Foundation).

Institution of Electrical Engineers, Electronics and Communications Section (at Savoy Place, London, W.C.2), at 5.30 p.m.—Prof. A. L. Cullen: "Applications of Microwaves".

University College (in the Anatomy Theatre, Gower Street, London, W.C.1), at 5.30 p.m—Prof. D. H. Wilkinson: "Language and the Elementary Particles".* (First of three Special University Lectures in Physics. Further lectures on February 25 and 26.)

Society of Chemical Industry, Food Group (joint meeting with the Microbiology Group, at 14 Belgrave Square, London, S.W.1), at 6.15 p.m.—Meeting on "New Methods of Factory Hygiene in the Food Industry". Mr. G. A. Thomas: "Chemical Sterilants in the Food Industry"; Mr. W. J. Blois-Johnson "Hygienic Considerations in Food Plant Design".

Pharmaceutical Society of Great Britain (at 17 Bloomsbury Square, London, W.C.1), at 7.30 p.m.—Dr. T. D. Whittet: "Pharmaceutical Fellows of the Royal Society".

Thursday, February 25

Central London Productivity Association, Working Relations Sub-Committee (at 21 Tothill Street, London, S.W.1), at 2.30 p.m.—Meeting on "The Factories' Act and the Work of the Factory Inspectorate".

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Prof. F. W. R. Brambell, F.R.S., Mr. W. A. Hemmings, Prof. C. L. Oakley, F.R.S., and Mr. R. R. Porter: "The Relative Transmission of the Fractions of Papain Hydrolysed Homologous γ-Globulin from the Uterine Cavity to the Fœtal Circulation in the Rabbit"; Prof. D. Lewis, F.R.S.: "Genetic Control of Specificity and Activity of the *S* Antigen in Plants".

Linnean Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr. G. Kuschel: "The Natural History of Juan Fernandez Islands"; Dr. M. W. Holdgate: "The Natural History in the South Chilean Islands".

Friday, February 26

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Prof. Alexander Kennedy: "The Scientific Lessons of Brainwashing".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Knoop Research Fellow (graduate in medicine or science), to work on cerebral enzymatic aspects and on the presence of chemical abnormalities in hereditary degenerative cerebral conditions—The Secretary, Institute of Neurology, The National Hospital, Queen Square, London, W.C.1 (February 25).

Lecturer (graduate of a British university, preferably with teaching experience) in Pure and Applied Mathematics in the Department of Building, Structural Engineering and Surveying—The Secretary, Hammersmith College of Art and Building, Lime Grove, London, W.12 (February 25).

Horticulturalist (male), to take charge of the Insecticide Department glasshouses—The Secretary, Rothamsted Experimental Station, Harpenden, Herts (February 29).

Keeper (graduate or holder of the Diploma of the Museums Association, a good knowledge of Western European archæology, and preferably an interest in the archæology of the Eastern Mediterranean) of Archæology—The Director, Leeds City Museum, Park Row, Leeds 1 (February 29)

Lecturer in the Department of Psychological Medicine—The Secretary, The University, Edinburgh (February 29).

Research Student in Metallurgy, for postgraduate work on liquid metals—The Registrar, King's College (University of London), Strand, London, W.C.2 (February 29).

Lecturer in Social Science, a Lecturer in Social Psychology or in Sociology, and 2 Leverhulme Research Fellows—The Registrar, University College, Singleton Park, Swansea (March 5).

Lecturer (with a good honours degree and teaching experience) in Chemistry at the Nigerian College of Arts, Science and Technology—The Council for Overseas Colleges, 12 Lincoln's Inn Fields, London, W.C.2 (March 5).

Research Fellow in Mathematics—The Secretary of University Court, The University, Glasgow (March 5).

Senior Lecturer/Lecturer in Fuel Technology in the School of Mining, Engineering and Applied Geology, University of New South Wales—Agent General for New South Wales, 56–57 Strand, London, W.C.2, and The Bursar, Post Office Box 1, University of New South Wales, Kensington, N.S.W., Australia, marking envelope "University Appointment" (March 5).

Assistant Professor (with high academic qualifications in physics or mathematics, and with experience in (*a*) experimental reactor physics, (*b*) the design of critical and subcritical experiments, and (*c*) safety precautions associated with (*a*) and (*b*), and with the use of highly radioactive sources) of Nuclear Science and Technology at the Royal Naval College, Greenwich—The Civil Service Commission, 17 North Audley Street, London, W.1, quoting S./5101/60 (March 10).

Lecturer (with a degree in veterinary science, together with postgraduate experience) in the Department of Veterinary Preventive Medicine at the University of Queensland, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, March 12).

Physiologist or Biochemist (honours graduate in physiology or biochemistry, with relevant postgraduate research experience) in the Cattle Research Laboratory, Division of Animal Genetics, Commonwealth Scientific and Industrial Research Organization, Rockhampton, Queensland, Australia, for the study of the adaptation of cattle to a tropical and subtropical climate—Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting Appointment No. 231/5 (March 12).

Lecturer in Physics (Cosmic Ray Group)—Prof. P. M. S Blackett, F.R.S., Physics Department, Imperial College of Science and Technology, Imperial Institute Road, London, S.W.7 (March 14).

Biochemists (2) (honours graduates in science (or equivalent qualifications), with suitable postgraduate research experience, preferably to Ph.D. level) in the Division of Biochemistry and General Nutrition, Commonwealth Scientific and Industrial Research Organization, Australia, for research into the intermediary metabolic processes of ruminant animals—Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting Appointment No. 250/92 (March 15)

LECTURER IN ZOOLOGY—The Secretary, The Queen's University, Belfast (March 15).

LECTURERS IN PURE MATHEMATICS—The Secretary, The Queen's University, Belfast (March 21).

SENIOR LECTURER (with special qualifications in hydraulics) IN CIVIL ENGINEERING at the University of Adelaide, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, March 21).

CHAIR OF PSYCHOLOGY—The Registrar, The University, Leicester (March 26).

LECTURER IN PSYCHOLOGY—The Registrar, The University, Leicester (March 26).

CENTRAL ELECTRICITY GENERATING BOARD RESEARCH FELLOW (of British nationality. and by October 1960, taken the degree of Doctor of Philosophy, or have had equivalent research experience), for research in the physical sciences, including metallurgy, engineering or mathematics—The Master Elect, St. Catherine's College Planning Office, 42 Banbury Road, Oxford (March 31).

PROFESSOR OF EDUCATION at the University of Queensland, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (March 31).

SECRETARY (with senior administrative experience in or with Governments, preferably in departments connected with science, agriculture or forestry; also overseas experience or experience in inter-commonwealth relations, and preferably aged 50 to 55 with a scientific background or training, and fluency in some foreign languages) TO THE EXECUTIVE COUNCIL OF THE COMMONWEALTH AGRICULTURAL BUREAUX—The Secretary, Commonwealth Agricultural Bureaux, Farnham House, Farnham Royal, Bucks (April 15).

IMPERIAL CHEMICAL INDUSTRIES RESEARCH FELLOWS IN BIOCHEMISTRY, CHEMISTRY, CHEMOTHERAPY, ENGINEERING, METALLURGY, PHARMACOLOGY or PHYSICS—The Academic Registrar, University of London, Senate House, London, W.C.1 (April 30).

TURNER AND NEWALL RESEARCH FELLOW IN ENGINEERING, INORGANIC CHEMISTRY or PHYSICS—The Academic Registrar, University of London, Senate House, London, W.C.1 (April 30).

LECTURER (preferably with experience of terrestrial ecology) IN ANIMAL ECOLOGY—The Secretary, University College London, Gower Street, London, W.C.1 (May 1).

NATIONAL RESEARCH COUNCIL OF CANADA POSTDOCTORATE FELLOW IN APPLIED MATHEMATICS—G. R. Magee, Department of Pure and Applied Mathematics, University of Western Ontario, London, Ontario, Canada (May 1).

RESEARCH SCHOLARS (with a good honours degree or graduate member of the Royal Institute of Chemistry) IN THE DEPARTMENT OF CHEMISTRY, for research in higher dispersion infra-red spectroscopy for Ph.D. or M.Sc. degree—The Professor of Chemistry, The University, Reading (May 2).

HOLLERITH RESEARCH STUDENT (graduate of any university), to undertake research in automatic computing or in a subject allied thereto—The Secretary to the Academic Council, The Queen's University, Belfast (June 1).

AGRICULTURAL CHEMIST (male, with a good honours degree in agricultural chemistry, with some postgraduate experience, preferably in the tropics) in Sierra Leone, to advise the Director of Agriculture on specific problems and for investigational studies in the field, including the laying out of field trials and their statistical analysis and interpretation—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.63/15/04/T.

ASSISTANT or ASSOCIATE PROFESSOR OF MATHEMATICS—The Principal, Victoria College, Victoria, B.C., Canada.

BIOCHEMIST (Senior or Basic grade) to the Rochdale Group of Hospitals, to work under the Consultant Pathologist and to carry out biochemical work for the hospitals and clinics of the Group—The Group Secretary, Rochdale and District Hospital Management Committee, Central Offices, Birch Hill Hospital, Rochdale, Lancs.

CHEMIST (Ph.D.), to supervise rock and soil analytical laboratory, a CHEMIST (honours B.Sc.), to assist in the study of sulphur compounds in oils, a CHEMIST (B.Sc.) to assist in gas adsorption studies, a CHEMICAL ENGINEER (B.Sc. or M.Sc, with a bias towards mathematics) for basic combustion research, and a CHEMICAL ENGINEER (B.Sc. or M.Sc.) to work on pipe-lining research—The Secretary, Research Council of Alberta, 87th Avenue and 114th Street, Edmonton, Alberta, Canada.

EXPERIENCED PHOTOGRAPHER FOR THE PATHOLOGICAL AND BACTERIOLOGICAL RESEARCH LABORATORY—The Administrative Officer, Sir William Dunn School of Pathology, University of Oxford, South Parks Road, Oxford.

FISHERIES OFFICER (with a university degree in marine biology and suitable postgraduate experience) in the Bahamas, to advise the Department of Agriculture on fisheries conservation, introduce new fishing methods and enforce the fisheries laws—The Director of Recruitment, Colonial Office, London, S.W.1, quoting Ref. BCD. 63/27/04/T.

GEOPHYSICIST or GEOLOGICAL ENGINEER (Ph.D. or M.Sc.), to work on groundwater hydrology; and a GEOLOGIST or GEOLOGICAL ENGINEER (M Sc), to work on problems of applied groundwater geology and hydrology—The Secretary, Research Council of Alberta, 87th Avenue and 114th Street, Edmonton, Alberta, Canada.

MASTER TO TEACH PHYSICS to Open Scholarship level—The Headmaster, Bolton School, Bolton, Lancs.

NATIONAL RESEARCH COUNCIL AND OTHER POSTDOCTORAL FELLOWS in all branches of chemistry, and PRE-DOCTORAL TEACHING RESEARCH FELLOWS (well qualified graduate students), for research work for the M.Sc. and Ph.D. degrees—Prof. C. A. McDowell, Department of Chemistry, University of British Columbia, Vancouver, B.C., Canada.

PHYSICAL CHEMISTS (graduates with a good honours degree, preferably with some postgraduate experience or Ph.D. degree), to join a team working on fundamental studies on the physical properties of high polymers—The Director, Arthur D. Little Research Institute, Inveresk, Scotland.

PRINCIPAL FISHERIES RESEARCH OFFICER (with an honours degree in biology with not less than six years postgraduate research experience, preferably in fisheries science or marine biology) with the Federal Government of Nigeria, to plan and carry out research connected with the sea and inland fisheries of Nigeria, including studies in the field of population dynamics, and to supervise a small research group—The Appointments Secretary, Federal Public Service Commission, Nigeria House, 9 Northumberland Avenue, London, W.C.2, quoting H.1/1.

SCIENTIFIC OFFICER, CHEMIST (with a good honours degree in chemistry, and preferably with some experience in foods and oilseeds analysis, and a knowledge of fumigant and insecticide analysis) with the West African Stored Products Research Unit, Federation of Nigeria, to undertake research into problems associated with storage of oilseeds and other food crops with particular reference to insect infestation with the object of evolving methods for reducing losses—The Director of Recruitment, Colonial Office, London, S.W.1, quoting Ref. BCD.153/14/05/T.

SENIOR LECTURER IN ELECTRONICS, a LECTURER IN ELECTRONICS OR MEASUREMENTS, a LECTURER IN GENERAL ELECTRICAL ENGINEERING, and an ASSISTANT LECTURER IN ELECTRONICS—The Secretary, Northampton College of Advanced Technology, St. John Street, London, E.C.1.

UNITED NATIONS COLLABORATION IN THE SOCIOLOGICAL SCIENCES

SOME ten years ago Mr. L. V. Berkner, as special consultant to the Department of State, Washington, surveyed the Department's responsibilities in international science. The subsequent report, issued in May 1950 and entitled "Science and Foreign Relations", made numerous positive recommendations to promote the utilization of science in shaping national policy, including the establishment of a science office in the Department of State, the appointment of scientific attachés and measures to encourage the interchange of scientific and technical personnel and the flow of scientific and technical information. The report was discussed at the time in these columns (*Nature*, 166, 81; 1950) and on subsequent occasions (for example, 170, 1033; 1952), and the importance of its recommendations has become increasingly apparent with the growth of technical assistance programmes and of other measures to assist the under-developed countries.

In January 1958, the United States Committee on Foreign Relations decided to undertake a review of conditions and trends in the world, and of the relevant policies and programmes of the United States, prompted partly by the impact which Soviet scientific achievements might have upon the relations of the United States with the rest of the world. The inquiry then instituted developed later into a series of some fifteen studies of various aspects of the problem designed to provide a simple forthright statement of the basic aims of the foreign policy of the United States, which would reflect the motives and aspirations of its people, identify the forces which may frustrate or promote those aims, suggest means of controlling those forms and examine their impact upon the conduct of American foreign policy and the adequacy of the organization for determining such policy. The first of these studies, dealing with "Economic Problems and their Impact", was issued in August 1959, but the second, entitled "Possible Non-Military Scientific Developments and their Potential Impact on Foreign Policy Problems of the United States"*, is of as outstanding interest to the scientific and technical world generally as it is to those concerned with assistance to the under-developed areas of the world (to which one section of the report is devoted), and more especially with technical assistance, and it merits close attention as fully as the original Berkner Report.

This study was made by the Stanford Research Institute for the Committee on Foreign Relations, and it explores, besides prospective scientific developments of the next decade and their potential impact on foreign policy, the possibility of making more positive use of science and technology. It does not except for brief discussion, deal with possible scientific contributions to problems of disarmament or examine developments in military technology; nor does it deal further with matters such as scientific attachés, the promotion of scientific exchanges and the support of scientific activities overseas, with which the Berkner Report itself was concerned. Broadly, the report points out that while scientific developments may help to solve some problems of foreign policy, unless deliberate measures of policy are taken, the progress of science and technology will do more to create or intensify than to solve such problems. In the absence of such measures, the combination of pressures may easily lead to their relief by the traditional methods of war, famine and disease. The great danger is complacency, for under present allocations of effort to research and the diffusion of results, the urgency of the problems is likely to increase faster than the means of solving them.

The national interest of the United States thus requires a more conscious direction of scientific activity in ways which promise to assist in attaining the country's international objectives. In other words, security and welfare themselves call for a re-appraisal of present allocations of scientific and technical effort so as to increase that directed toward meeting the non-military challenges of foreign policy. The report suggests that the Committee on Foreign Relations could take steps to stimulate additional research and development directed specifically at important problems in that field, and indicates particular types of problem which call for such attention. It also suggests that steps could be taken to double or triple the amount of fundamental scientific research in fields where progress in scientific understanding is particularly important to foreign policy, and that the Committee should encourage the international proclivities of science and scientists to build bridges of understanding. Concrete suggestions include more international scientific conferences and interchange of personnel, international research programmes, an international centre for translation and scientific information, a world-wide attack on the problems of economic and social development in an 'International Development Year', and a lead in establishing a United Nations university. Foreign policy planning of the broadest kind, utilizing the best scientific assistance, will be a critical requirement in the years ahead, and this should include continual review of prospective scientific developments and their significance for international relations.

In this report the relations between scientific developments and foreign policy are discussed in the first chapter, including both the way foreign policy has been affected in the past, the nature of the connecting links and the possibilities both of anticipating and shaping scientific developments. The second section, dealing with future problems of foreign policy in the light of scientific developments, which in successive chapters covers science and national sovereignty; population, food and science; science and the under-developed countries; energy, materials and trade; and science and international communications; it approaches these problems primarily but not exclusively from the point of view of the United States. Nevertheless, like the section on future policy, where the positive use of science to achieve international goals is more particularly considered, it contains much that is fully relevant to those concerned with science and with foreign policy in other countries, and the whole report deserves the closest attention not only of the Secretary of State for Foreign Affairs in the United States but also of the Minister for Science and the Advisory Council for Scientific Policy in Great Britain. The picture displayed of the immense array of complex interlocked problems calling for urgent action applies fully as much to Britain, and it may be even more imperative for both the security and the welfare of Britain that the right priorities should be determined and our limited resources applied in accordance with them.

---

* United States (86th Congress, 1st Session). United States Foreign Policy. Possible Nonmilitary Scientific Developments and their Potential Impact on Foreign Policy Problems of the United States. A Study prepared at the request of the Committee on Foreign Relations, United States Senate, by Stanford Research Institute. Pp. ix+100. (Washington, D.C.: Government Printing Office, 1959.)

This is especially evident in the chapter of the report which considers the positive use of science to achieve international goals. The evidence presented there of the accelerating rate of discovery and invention applies generally. All over the world the number of scientists and technologists is rapidly increasing, and also expenditure on research and development. The increasing efficiency of diffusion of new ideas and techniques, and the more powerful tools of investigation available to scientists and technologists, act in the same way as does the expansion of organized team-work and the more favourable social attitudes, while to-day international competition and emulation tend to spur scientific and technical development and could easily do so in ways wasteful of the world's resources. Nevertheless, there are fields in which scientific effort is still undesirably low, and the report remarks on the effort specifically directed towards the peaceful achievement of objectives of foreign policy and the basic problems of human relations and social organization, including international aspects of such problems.

The report, in discussing next the positive use of science, makes some specific suggestions regarding non-military aspects of problems of foreign policy in which insufficient attention has been given to the possibility of attack by adequate fundamental research in the relevant sciences. It suggests, for example, that a responsibility should be established within the Government for continuing review of prospective scientific developments and their impact on foreign policy. In Britain, this would now appear to rest unequivocably with the Minister for Science and the Advisory Council for Scientific Policy. More specifically, the report quotes problems in oceanography, the polar regions, the atmosphere and space research, but stresses the need to include also studies of a legal, political and administrative as well as physical and biological character. Again, it is asked whether sufficient positive use of science is made in developing and adapting promising methods of improving food production, making the most effective use of American surpluses and exploring the possibilities of population control. Next, there are problems of planning for new world relations in production and trade, such as assessing the new competition and market opportunities likely to result from the spread of modern technology to the formerly under-developed countries, or the possibility of making long-term analyses of world supplies of raw materials and energy, and of world trade patterns. Problems of communication with other nations provide another set of problems in social science, and there are others of international political organization, law and administration where further research on political systems and legal and administrative systems might disclose the best ways of strengthening the United Nations and advancing towards a world rule of law.

In two particular sections, the report deals at greater length with the possibilities of action and the range of problems presented. First, in the matter of arms control and disarmament, besides the technical problems of control of armament and the devising of systems of inspection to prevent violation calling for constant research, the economic repercussions and adjustments should be explored, so that the individual nations are ready to deal with the consequences should a substantial measure of disarmament become possible. The report emphasizes the need for a continuing study, adequately financed, to deal with such technical problems as observation techniques, including radar, aerial photography, ground observers, seismic means for monitoring nuclear explosions, problems involving communication and data-processing systems.

Secondly, the development of under-developed countries presents a wide range of problems in which specific research is likely to assist materially. The report mentions simpler and cheap power sources for villages and towns, including electrical generators from local resources, gas from agricultural wastes, etc., wind-power, solar energy, storage of energy and small nuclear power stations. Improved but simple and cheap housing materials and constructional methods offer other possibilities, as does water supply for irrigation and industrial use, for example, by cheap desalting processes. Simple, cheap methods of refrigeration for foods and cooling of houses; environmental sanitation; the control of special diseases, such as hepatitis, filariasis, brucellosis, trachoma, dysenteries; food preservation; the improvement of food crops and animals; and the control of the growth of population—all these present physical science with urgent research problems.

Attention is also directed to the range of problems in sociological and social research presented by the improvement in techniques of planning development programmes, by development of simple, cheap methods of mass education, the diversity of methods of introducing agricultural and rural improvements, communicating effectively with people, and inducing them to adopt better practices. Methods of introducing modern industrial techniques and meeting problems of industrialization, and government methods compatible with democratic ideals but more suitable to the special circumstances of the under-developed countries, offer another fruitful field for such research, and much emphasis is laid not only on the need for fundamental research in the physical, as well as in the pyschological and social sciences, but also for better theories. The major need, it is asserted, is for better interpretation of the facts, better understanding of their meaning in terms of our aims, ideals and plans, and for better founded notions about the probable effects of one course of action or another.

It is not suggested in the report that simple solutions to these problems are likely to be found, but there is sound sense in the argument that it is at least possible that imaginative, carefully designed basic research could eventually throw light on the soundness of even such a difficult problem as the foundations of the psychological assumptions of the theory of deterrence on which much of the Western policy for preventing nuclear attack is based. Excluding the military aspects, the problems of foreign policy are overwhelmingly human ones, and the psychological and social sciences, to which the makers of foreign policy should be able to, and, to a significant extent do, look for insight and help, are the least well developed and least well supported of the major scientific groups. Without expecting quick and easy solutions to problems of human relations, there is ample basis for believing that more effort in this field could lay the foundations for much better understanding of the nature of some of the problems that arise in foreign policy and considerably help those who make it. The president of Stanford Research Institute, Mr. F. Finlay Carter, unhesitatingly affirms his belief that research can make many contributions to the better understanding of the invisible but very real forces affecting human behaviour, human relations and human institutions.

In view of the establishment last year in Britain of the Overseas Research Council, it is interesting to note that the report suggests that the United States Government should be provided at some appropriate point with an office of research and development concerned with problems of under-developed areas, and that such an agency could initiate a systematic programme for identifying problems where scientific and technological discovery could assist to accelerate development and that it could then stimulate research on these problems, either in the United States or abroad. Even in the physical sciences, the problems of this type are in some way or other neglected in the post-war world; and it is obvious that their solution must involve some redistribution of resources.

That is one sound reason for advocating that the attack upon them, where possible, should be made by international agencies; and not the least important section of this highly suggestive report is that where, in conclusion, it discusses the possibility of encouraging the tendencies of science and scientists to work across national frontiers to build bridges of understanding between East and West—between the under-developed and the industrially advanced nations. The value of scientific conferences and the interchange of scientists and scholars at all levels is recognized in the first place, and some stress is also laid on the contribution which advances in mechanized translation and information facilities could make both by improving communication between scientists and reducing the language problems of mankind. Moreover, it has already been widely recognized that some of the fields of research to which the report directs attention can be prosecuted to advantage by international agencies or by the co-operation of research institutions in several countries. Examples are to be seen in oceanography, polar and space research, and the atmosphere; and the report of the International Council of Scientific Unions indicates not merely that a start has already been made, but also something of the possibilities, given substantial financial backing and goodwill. Arctic and deep-sea research are instanced as further possibilities which merit examination, and also the establishment of a United Nations weather and climate agency.

The proposal regarding the under-developed countries already noted deserves special attention as indicating a novel approach to a problem of growing urgency and importance. The International Development Year suggested would initiate, much on the lines of the International Geophysical Year, fundamental new studies on an international basis on the key development problems of under-developed countries, and would stimulate the fundamental research in these aspects of the physical, biological, psychological and social problems from which contributions to the solution of these problems might be expected. The United Nations university scheme, which, it is suggested, the United States might also take the lead in establishing, would possibly include a World Institute of Social Technology, for advanced research and teaching in the practical application of psychological and social science to problems of human relations and social organization, especially where they bear on these problems; but the major purpose of the university scheme would be the advancement of science and the humanities, and thereby the discovery and development of the unifying elements in the human values widely held by the different groups and cultural traditions of mankind. It is suggested that the system might be financed by an annual contribution of 0·1 per cent of the annual expenditure of each member of the United Nations on military defence, or an agreed fraction of the index of the total national product.

No reader of the report is left in any doubt as to the danger of failing to give much greater attention to the significance of scientific and technological advance for national policy, including foreign policy, or as to the improbability that an adequate attack can be made on many of the problems now confronting us except on an international basis. The facts that the creation of a Minister for Science and the existence of an Advisory Council for Scientific Policy in Britain, together with the clear recognition that Britain's contribution to space research should be made on an international basis, place this country in an advantageous position to co-operate in this way, is no ground for complacency. The suggestions made in this report and their implications deserve to be closely considered by the Minister for Science, the Advisory Council for Scientific Policy and the Overseas Research Council at least, with a view both of increasing our present effort and ensuring that it is concerted as effectively as possible in co-operation with that of other nations.

POST-MORTEM ON GROUNDNUTS?

Agriculture and Ecology in Africa

A Study of Actual and Potential Development South of the Sahara. By Prof. John Phillips. Pp. 424. (London: Faber and Faber, Ltd., 1959.) 63*s*. net.

POLITICAL advances in tropical Africa can only be successful if economic progress is accelerated. Industrial developments are important, but for many years agriculture in one form or another will be the major industry of all the countries in Africa south of the Sahara. Today agricultural progress is slow, and where crops have brought prosperity, as cocoa has to Ghana, this is because the price has risen disproportionately to the rise in other world prices, and not because the yield has risen substantially. Unless methods of agriculture in many countries are greatly improved, as the population increases even the present pitifully low standards of living will be difficult to maintain.

Prof. Phillips's book is about this problem. He has been himself concerned with ecological and agricultural works in many parts of Africa for nearly forty years. He was the botanical ecologist in Swynnerton's team of tsetse fly investigators in Tanganyika. He was professor of botany at the University of the Witwatersrand. He was one of the senior scientists concerned with the ill-fated East African groundnut scheme. Since 1952 he has been professor of agriculture in the University College in Ghana. Few men can have seen so much of African agriculture, and have been made so aware of its problems.

In this book an immense amount of information about the climate, soil, crops and people of Africa is brought together. It must have been a tremendous task for the author to make this compilation, and his book will at least serve as an invaluable work of reference to those unable to go to the original sources. I do not think that it will succeed so well in its avowed purpose "to awaken those concerned with Africa to the necessity of adjusting both traditional and modern agriculture to the ecological, sociological and psychological settings of the Trans-Sahara".

The first disadvantage of this volume is that it is so difficult to read. The (very valuable) data are set out at length, usually undigested, and I found I could only assimilate those in which I had some particular and personal interest. Between the data the reader is treated to infuriating examples of flowery prose in Prof. Phillips's own particular style. In one paragraph three consecutive sentences start: "Sketchy is the information . . .". "Essential is the need . . .". "Unnecessary is a review . . .". We are, however, left with a true picture of Africa, vast, varied, and (in the main) unproductive; but this could have been much more easily achieved and with less strain on the reader.

What should have been the most valuable chapter compares three large-scale development schemes. These are the Sudan Gezira Scheme, the East African Groundnut Scheme, and the proposed Volta River Project in Ghana. We are shown how fundamentally different the conditions for the successful Gezira Scheme and the groundnut fiasco were, but instead of a straightforward account of each we are treated to a point-by-point comparison of features which are not always strictly comparable. We can in the end only conclude that in the Gezira conditions were favourable, and in Tanganyika everything was done in too great a hurry.

It is difficult to imagine how this book can have any important and practical results. We are told that agriculture must be ecological, which simply means that we must learn to grow the correct crops by the best methods in the best places. We are not told how to do this, except that we must not be in too much of a hurry, and that research must be properly co-ordinated.

In my opinion the trouble with African agriculture is not that information is not properly co-ordinated, but that the basic facts are simply not known. So little fundamental agricultural research has been done. Even in Britain we spend more in subsidizing our poultry industry for a month than we spend on agricultural research in a year; in Africa, with its immense areas and problems, we spend much less. Even attempts at developments like the Groundnut Scheme, into which millions of pounds were poured, seem less wasteful when it is realized that for every pound lost in this and in all agricultural schemes attempted in Africa since the War, much more than a hundred pounds has been spent in subsidizing British agriculture at home. More money will have to be spent on research in Africa. We need to have more and better research workers in the laboratories and in the field; I believe they will use the limited resources better than those who fritter away so much time and money attending international conferences and endless meetings of co-ordinating committees which lack the basic facts to co-ordinate. If the newly independent territories in Africa can learn this lesson, and develop an environment favourable to working scientists (expatriate as well as local), there is a reasonable chance that they may learn to take proper advantage of the ecological conditions of their countries in agriculture as in other fields of development.

KENNETH MELLANBY

CHANGING COASTLINES

Beaches and Coasts

By Dr. C. A. M. King. Pp. xii+403. (London: Edward Arnold (Publishers), Ltd., 1959.) 65*s*. net.

IT is now forty years since the publication of D. W. Johnson's pioneer and now classic work "Shore Processes and Shoreline Development". In the meantime much work has been carried out, both theoretica and practical, on the processes at work along the coasts and the evolution of different types of shoreline Problems of coast erosion and, equally, of coasta accretion have long been matters of much concern to civil engineers who, in the absence of precise investigations, were compelled to use empirical methods. Work in recent decades has been full of surprises. Though the widespread occurrence of steep-sided offshore canyons around the coasts is one of the surprises, this lies beyond the scope of the present work, where a beach is defined as an accumulation of loose material around the limit of wave action—extending through a zone divided into backshore, foreshore and offshore, from the extreme upper limit of wave action to the depth at which waves approaching from deep water first cause appreciable movement of the bottom materials. This scholarly, well-documented treatise first defines the four main factors on which the character of a beach depends, namely beach material, waves, tides, winds. It then considers briefly the three parallel methods of research—theoretical, experimental (especially wave-tanks such as that long in use in the Department of Geography at Cambridge) and field observations. A fourth approach, the historical, is mentioned, but sufficiently detailed information is rarely available. The main topics are then taken up in the order of waves, movement of material, beach profiles, effect of wind, classification of beaches and coasts, constructive and destructive wave action, and, finally, the marine cycle. Examples are drawn from world-wide sources with a particularly thorough examination of all the work around Britain.

Every point is substantiated by appropriate references, and nowhere is the reader left with the impression that all is adequately known and understood. Instead, the memory of the disastrous coastal floods of 1953 is still fresh in England; what may prove to be the tragic mistake of closing to scientific research the great natural laboratory of Dungeness is within the last few months. There is no doubt that protective works in one area have unexpected results in another; if half a million acres of tidal flat are awaiting 'reclamation', as some would claim, it is vital to know what will be the consequences elsewhere. The field of study covered in this book is part of the important new field of applied geomorphology. It is perhaps inevitable, if regrettable, that a new 'jargon' should arise that one needs to study the dilatancy and thixotropy of sediments. But perhaps the deliberate creation of new words is safer than the attempt to define by size granules, pebbles, cobbles and boulders, or to insist on new exact meanings for berm and runnel.

L. Dudley Stamp

PRECIS OF PROGRESS IN BIOCHEMISTRY

Progress in Biochemistry

A Report on Biochemical Problems and on Biochemical Research since 1949. By Prof. Felix Haurowitz. Pp. xii+357. (Basel: S. Karger; New York: Interscience Publishers, Inc.; London: Interscience Publishers, Ltd., 1959.) 60*s*.; 8.50 dollars.

THE fifth in Prof. Haurowitz's series of reports on progress in biochemistry deals with the advances in this field since 1949, and we gather from the author's foreword that he was hesitant to prepare it. He comments that "limits of time and human endurance make it more and more difficult to grasp, let alone to master, the entire field of biochemistry". This *cri de cœur* will surely find an echo in many laboratories and lecture rooms, and for this reason alone, quite apart from the book's intrinsic merits, it is likely that Prof. Haurowitz's courage and virtuosity in grappling with the smothering excess of the printed word will earn the reader's gratitude.

But his claim to our thanks is more firmly founded for there can be no doubt that, within his terms of reference, he has written a most useful book, which gives fluent accounts of the progress made in all those aspects of the subject normally dealt with in the standard text-books. His method has its own particular merits: thus, except where a brief reminder may help the correlation of recent advances with established work, it is free from the necessity of giving the repetitious background to knowledge which necessarily swells each general text-book in turn. On the other hand, because it reports the work of a decade it is frequently able to focus topics which an annual review sees only as the indistinct blur of work-in-progress; moreover, it is spared the uncritically comprehensive list of references which can so effectively throttle the text of more definitive reviews. In ten years a measure of sifting becomes possible, and the references retained and commented upon here seem to have been chosen with excellent discrimination.

Taken on this level, therefore, as a series of timely supplements to the general text-books, these volumes may be judged to have introduced successfully a new style of reporting into biochemistry. Necessarily they risk the defects of any anthology; there may be omissions and faults of emphasis. But it is certain that most readers will find new and stimulating expositions in the pages of this latest volume, and even be led to an appreciation of new aspects of the subject which had lain unregarded by them in the more specialist literature.

F. H. Malpress

APPLIED MICROBIOLOGY

Advances in Applied Microbiology

Vol. 1. Edited by Wayne W. Umbreit. Pp. xi+304. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1959.) 9.50 dollars.

THIS volume is presented as the first of a projected new series of reviews on microbiological topics of interest to the practical microbiologist. Applied microbiology is, in its widest sense, a subject that covers or overlaps considerable areas of present-day scientific research. In recent years the synthetic and degradative powers of micro-organisms have been increasingly harnessed in the laboratory and factory, as microbial synthesis has often proved the only convenient method of preparing a number of compounds important in pharmacy or nutrition.

Three chapters are on general problems of large-scale fermentation: P. Gerhardt and M. C. Bartlett classify the types of continuous fermentation and consider their theoretical basis and practical applications, M. Herold and J. Nečásek discuss the value of the use of antimicrobial agents to control contaminating micro-organisms that interfere with industrial fermentation processes, and R. F. Robinson and R. S. Davidson give an interesting account of the problems attending the large-scale production of edible fungi and urge greater consideration of the use of the higher fungi to convert carbohydrate-containing wastes into foods rich in fat and protein. In the three articles concerned with the use of micro-organisms as synthetic tools D. Perlmann gives a comprehensive and fully documented account of the biosynthesis of vitamin B_{12} and its analogues, A. L. Demain contributes a critical discussion of the biosynthetic pathway leading to penicillin, with particular reference to the synthesis of the β-lactam-thiazolidine ring nucleus, and S. Kinoshita introduces the new and rapidly developing field, largely pioneered in Japan, of amino-acid production by fermentation processes.

Articles dealing with the control of micro-organisms include a discussion of the antimicrobial activity of phenols by E. O. Bennett, a brief review of the use and mode of action of antibiotics in the control of plant diseases by D. Pramer, and a general outline of some of the problems associated with the application of radiation preservation to food and pharmaceutical products by W. D. Bellamy. A. W. Phillips and J. E. Smith trace the development of the methods used for the rearing of germ-free animals, list their characteristics and consider some of the many uses to which such animals have been, or can be, put. In the remaining chapter, S. R. Dutky contributes a valuable discussion of the application of specific micro-organisms in the control of insects, a procedure that eliminates many of the hazards to plants and animals presented by the use of insecticides.

The eleven chapters in this book deal with a representative selection of topics, and the diversity of the subjects is no doubt responsible for some of the differences apparent in the level of treatment in individual articles. The book is well presented, adequately indexed and should surely be welcomed as the first of a useful series.

J. W. G. PORTER

TRAINING APPRENTICES

Apprenticeship

An Enquiry into Its Adequacy under Modern Conditions. By Kate Liepmann. (International Library of Sociology and Social Reconstruction.) Pp. x+204. (London: Routledge and Kegan Paul; New York: The Humanities Press, Ltd., 1960.) 23s. net.

FOR two years a small group of investigators from the University of Bristol made an inquiry into systems of apprenticeships in firms in the Bristol area and in an agricultural area in North Somerset. Information was obtained from both the managerial and trade union sides of industry, as well as from technical colleges and relevant Government departments. Dr. Kate Liepmann was directly responsible for the study and here sets down details of the way the inquiry was made and a record of the findings.

The industries investigated—engineering, printing and building—were selected because of their local importance and because of significant differences in apprenticeship conditions, degrees of mechanization, 'de-skilling' and attractiveness to boys. An industry without apprenticeship, boot and shoe manufacture, was included for comparison. Most of the firms approached readily provided the information requested by the investigators. One large printing firm refused any information after a preliminary interview. Another big printing firm and the area's biggest engineering firm allowed the research workers access to certain senior executives but to no other employees. Information from these was obtained in other ways, but the omissions detracted from the value of the survey.

There is no reason to reject Dr. Liepmann's belief that the observations made during her Bristol survey would not be applicable to Britain as a whole. Its value is that this is an investigation carried out by professional research workers with no axe to grind, holding allegiance neither to employers, trade unions, technical college principals, nor Government agencies, and concerned only to record their findings quite impartially.

From the nation's point of view the scene described is depressing to contemplate. Instead of a means to build up the quality of human beings and to increase the country's resources of skilled craftsmen, the apprenticeship system is used by both sides of industry to further their respective sectional interest. "All the modifications made in adjustment to technical and other developments have been made in such a manner as to preserve the power of employers and trade unions to bend apprenticeship to their own ends".

The criteria for judging the workings of the apprenticeship system should be examined to see whether it supplies sufficient workers with the requisite skills, is efficient and economical to operate, and its effect on productivity. Dr. Liepmann's investigations show that industry is not training nearly enough apprentices with a wide degree of skill which will enable them to adapt themselves to changing technological needs. Nearly every firm looks after its particular interest and many of them rely on 'poaching' craftsmen from other firms to supply their needs. She rightly concludes that it is not in the best interests of the community that the number of apprentices should be determined by industry itself.

As a contribution to productivity the apprenticeship system leaves much to be desired. Although, as part of their training, apprentices make some contribution to productivity, the apprenticeship scheme leads to a widespread system of restrictive practices; rigid demarcation between trades impedes good manpower utilization, thereby lowering efficiency and increasing the cost of production: and, unfortunately, the demarcation which was formerly exclusive to apprenticed craftsmen is now being extended to a much wider class of workers, with further damage to productivity.

Despite the hope that some developments in the trade union movement may lead to the emergence of an attitude more in line with modern conditions, Dr. Liepmann concludes her inquiry with the firm belief that the State should take the prime responsibility for training for industry, both in its quantitative and qualitative aspects.

This is the second of two recent studies of the workings of the apprenticeship system by academic workers. Their observations are almost identical and should cause wide-spread concern. If the Ministers of Labour and of Education could be persuaded to read this or Lady Williams's book, they would see that the exhortations to industry of their predecessors have been so much wasted breath. Without a change in policy for the training of young workers, within twenty years Britain may face grave shortages of skilled and adaptable craftsmen.

Out of Doors

Edited by Winwood Reade. Pp. 160. (London: Rathbone Books, Ltd., 1959.) 12*s.* 6*d.* net.

"OUT OF DOORS" is a book written specially for children with the purpose of catching their interest and encouraging their observations of wild life. It cannot fail to do either. By dividing the book into twelve chapters, one for each month of the year, it provides a perpetual stimulus.

Under each month there are four sections. The first deals with things that can be seen out of doors. A large number of general facts are given here, as well as the specific observations for the particular month. The easy style and abundant illustrations of this first section set the tone for the rest. Secondly, there is an excellent article on one particular topic, written by a well-known naturalist. The third section of each month describes, very simply, something practical that can be made, done or collected. The last section is always two picture puzzles. These may be difficult for children; but even if they do not actually know the answers they will enjoy guessing, and learn something by looking up the correct answers in the back of the book.

The book combines all the qualities that enable a child to learn enjoyably. Not only is it highly informative, and infectious in its enthusiasm for the subject; it also appeals to a child's love of practical work, and encourages him to use his eyes. These qualities make "Out of Doors" suitable for even the young child. At the same time, many adults will be more than pleased to widen their knowledge of birds, trees, flowers, insects, animals, etc., in such a straightforward manner.

There are no coloured plates, which one misses, perhaps, in a book of this kind, and which always catch the eye, but this is more than made up for by the numerous excellent black-and-white illustrations. B. J. G. MAITLAND

The Waterfowl of the World

By Jean Delacour. Vol. 3: Eiders, Pochards, Perching Ducks, Scoters, Golden-eyes and Mergansers, Stiff-tailed Ducks. Pp. 270+20 plates. (London: Country Life, Ltd., 1959.) 126*s.* net.

WITH this third volume Mr. Delacour completes his account of the ducks, geese and swans of the world; we thus now have a comprehensive modern work on the Anatidae by a recognized authority, with Mr. Peter Scott's colour figures of the birds in their various plumage phases and useful distribution maps. The information given for each species or sub-species covers description, distribution, general habits and record in captivity—this last of special interest to the aviculturist.

Vol. 3 begins with the eiders, including the familiar British species. It proceeds to the pochards, narrow-billed and broad-billed respectively. Next come the perching ducks (or tree ducks), including the Carolina wood-duck so familiar in captivity and the beautiful mandarin duck which has lately become feral in England; the rest are tropical, including the so-called pygmy geese, the unique comb duck, the spur-winged goose, and the muscovy duck—the last a South American species which has been domesticated and is often crossed with the domestic mallard. Then we come to a group which includes such largely marine diving ducks as the scoters and golden-eyes and also the saw-billed ducks or mergansers. Finally there are the stiff-tailed ducks, including the strange musk duck of Australia and the aberrant black-headed duck of South America, which has the cuckoo-like habit of foisting its parental duties on other species.

Looking at this fine work as a whole—all three volumes—one is impressed by the great range of interest to be found within a group so relatively uniform that most of its members are included in a single sub-family. It is gratifying to have the information so competently and handsomely brought together. LANDSBOROUGH THOMSON

Uganda in Black and White

By Hugh B. Cott. Pp. xxvi+232 (109 figures). (London: Macmillan and Co., Ltd., 1959.) 30*s.* net

AN unusual and delightful volume which seeks to fascinate the reader with the beauties of Uganda and its inhabitants by means of no less than 109 full-page drawings with brief explanations on the opposite pages. There is a short foreword by Sir Andrew Cohen, a former governor of the Territory, and a not much longer introduction by the author, and then we come to the pictures. Dr. Cott is interested in crocodiles, and the main reason for his sojourn in Uganda was to study the habitat of these unpleasant beasts. But he is also an artist with a keen eye for the country and the people. Much more can be done with drawings than is possible with photographs. The latter are doubtless factually correct, but there is something that drawings can give which the unselective photograph cannot. Dr. Cott is interested in the old Uganda, not in its Westernized modern developments. He does not pretend to have visited every single part of it, but he does give us pictures from many regions. There are pampas swamps and country scenes, dhows on Lake Victoria, a Muganda lady, and, of course, some crocodiles. A lovely picture of the Ripon Falls before they vanished when the new dam was built can be taken in conjunction with another two of the Murchison Falls. Then there are giraffe browsing and a serval cat, not to mention elephants, rhinoceros, and and an Ankole cow. Some of the characteristic carvings in hard wood of various animals, etc., are also illustrated, as well as the people themselves. Altogether a delightful volume which it is a pleasure to possess. M. C. BURKITT

A Geography of Ghana

By E. A. Boateng. Pp. xvi+205+24 plates. (Cambridge: At the University Press, 1959.) 21*s.* net.

ALTHOUGH primarily intended for school examination candidates and first-year university students, this book deserves a wider public. Written by a Ghanian, who is now senior lecturer in the University College of his own country, for his own people, it reaches a high level in selection and presentation of material. An enclave surrounded by French-speaking territory, there has been some tendency for Ghana to be surveyed and studied in isolation, and it is useful to have summaries of local work in geology (with explanation of the special terminology), vegetation, soil and agriculture. A third of the book is devoted to a systematic treatment of the contrasted geographical regions. An excellent series of 41 photographs and 46 text figures and maps, all carefully prepared, completes a book of which Ghana may well be proud. L. DUDLEY STAMP

THE CERN PROTON SYNCHROTRON

By J. B. ADAMS

IN a recent article in *Nature*[1], in which a short review of the work of the laboratories of the European Organization for Nuclear Research (CERN) at Meyrin near Geneva, Switzerland, was given, it was mentioned that a 25-GeV. alternating gradient proton synchrotron was in an advanced stage of construction (Fig. 1). This accelerator has now been put into operation. Towards the end of November 1959, protons were accelerated up to 24 GeV. kinetic energy, and a few weeks later, after adjustments had been made to the shape of the magnetic field at field values above 12,000 gauss by means of pole-face windings, the maximum energy was increased to 28 GeV. The intensity of the accelerated beam of protons was measured as 10^{10} protons per pulse and there was no noticeable loss of particles during the whole acceleration period up to the maximum energy. The CERN proton synchrotron has thus fulfilled the expectations of its designers and the hopes of the twelve European countries that have supported the work for the past six years. It seems appropriate on this occasion to give a short account of this project together with a brief description of some of the design problems and preliminary measurements of the operating characteristics of this accelerator.

In June of 1952, at a conference in Copenhagen, the Interim Council of CERN decided to start an engineering design study of a 10-GeV. proton synchrotron that was to be the principal high-energy accelerator for nuclear physics research in Europe. The cost of this machine was considered to be so large in relation to other expenditures in physics research that no one European country felt justified in financing it alone. Hence several countries had combined their resources in order that physicists should have available in Europe the highest-energy accelerator that was thought feasible at that time. By July 1952 a design group of three people was set up with Dr. O. Dahl in charge, and in August this group, during a visit to Brookhaven on Long Island to see the cosmotron at first hand, learnt of a new idea for making cheaper and higher-energy machines. This idea was considered so attractive that in October 1952 the CERN Council was persuaded to drop the engineering study of a 10-GeV. proton synchrotron and instead to set up a theoretical study of the new principle. It seemed that a 30-GeV. machine might be built for the same cost as a 10-GeV. cosmotron type of machine. It is interesting to note that at this time, and quite unknown to the Western world, Russian scientists were planning a scaled-up version of the Berkeley bevatron for 10-GeV.

In December 1952 the Proton Synchrotron Group was formed to augment the original staff of three, and the members of this group, most of them honorary part-time members, remained in their own laboratories and institutes. Members of the theoretical section worked at the Atomic Energy Research Establishment, Harwell, and at the Universitetets Institut for Teoretisk Fysik, Copenhagen. The magnet studies were concentrated in the Laboratoire de Radioélectricité de l'Université, Paris. The radio-frequency problems were studied at the Institut für Physik, Max-Planck-Institut, Heidelberg. The radiation shielding problems at such high energies were worked out using cosmic ray data at the Physikalisches Institut der Universität, Freiburg-i.B., Germany, and the general engineering problems remained at the Chr. Michelsens Institutt, Bergen, Norway, where for six months two of the senior staff of the cosmotron, J. P. Blewett and M. H. Blewett, gave invaluable assistance with the general design problems of the new machine.

By October 1953 enough was known about the implications of the new idea to present a tentative design of an accelerator to the Council of CERN. In America, meantime, the Brookhaven group and another at the Massachusetts Institute of Technology, Boston, had been working on similar problems. At the end of October a conference was held at the Institute of Physics of the University of Geneva, to which were invited representatives of the American groups, the

* This includes all staff directly connected with the design and construction of the machine

scientific members of the Council of CERN and other European scientists. The CERN Proton Synchrotron Group gave a series of lectures on its work of the previous ten months and presented a design for a 30-GeV. proton synchrotron using the new alternating gradient principle. It was found that the Brookhaven group had arrived independently at a very similar design.

Immediately after this conference the CERN Council fixed the energy of the machine at 25 GeV. and agreed that the members of the Proton Synchrotron Group should come together in Geneva, near which city the new European laboratory was to be sited. The State of Geneva and the University generously offered temporary laboratory accommodation, and by December 1953 most of the group had moved to Geneva with their families, and the task of designing the final machine started. Soon after this move Dr. O. Dahl resigned as director of the group, and the group suffered a further loss by the sudden death of Dr. F. Goward, who had been acting as deputy director. Despite these initial set-backs the group successfully established itself in Geneva. From the beginning of 1954 onwards staff was steadily recruited from all over Europe, and the group was built up as shown in Table 1.

The alternating gradient principle has been described many times. The original idea was published by E. D. Courant, M. S. Livingston and H. S. Snyder[2] and, quite unknown to these authors, was previously invented by N. Christofilos. In the conventional synchrotron the focusing of the circulating particles is achieved by arranging that the magnetic field which guides the particles around a fixed radius decreases slightly with radius. The amount of focusing achieved in this way is not very great, and consequently the amplitudes of the free oscillation of the particles are large and the dimensions of the magnet gap correspondingly large. Most of the cost in the original synchrotrons is in the magnet; for example, the Russian 10-GeV. synchrophasotron magnet, the radius of which is 30·5 m., contains 35,000 tons of steel and the magnet gap is 150 cm. wide and 40 cm. high. Although greater focusing can be obtained in the axial direction by increasing the gradient of the magnetic field, the criterion for radial stability is then violated. It is the great advantage of the alternating gradient principle that the focusing of the circulating particles can, in theory, be made as strong as one wishes and the amplitudes of oscillation of the particles as small as desired. This is achieved by alternating the sign of the gradient of the magnetic field many times around the circumference of the machine. The net result of this stronger focusing is to reduce greatly the weight of the magnet; for example, the CERN 25-GeV. proton synchrotron magnet has a useful aperture of 14 cm. × 7 cm. and contains only 3,400 tons of steel. It is 100 m. in radius, that is, three times the radius of the Russian machine and one-tenth the steel weight.

These attractive advantages are realized at the price of greatly increased accuracy in manufacturing and aligning the magnet of the synchrotron. Also, once the magnet is set up with the required precision, it must remain in place and, for a machine 200 m. in diameter, this presents some interesting foundation problems. The CERN proton synchrotron magnet is made up of 100 supposedly identical magnet units, each about 4·3 m. long. The magnetic field error between these units for the same energizing current should not exceed about one part per thousand, and the units should be set up with a precision of a few parts per million (0·3 mm. in 100 m. radius). The units are mounted on a free-floating monolith ring of concrete 200 m. in diameter and 2 m. × 2 m. in cross-section, and the machine is built in a subterranean annular tunnel in which the temperature is controlled to ± 1° C. As a further precaution, the concrete ring has steel pipes cast in it, and water is passed round the ring to prevent any part assuming a temperature different from the rest. The technology developed for the magnet construction and the foundations has been described in various CERN reports[3,4].

Another advantage of the alternating gradient principle is that the amplitude of momentum oscillations is very much smaller than in the conventional synchrotron. Since these momentum oscillations result in radial movements of the particles which have to be contained within the width of the magnet aperture, the alternating gradient synchrotron is again more economical in magnet aperture than the conventional synchrotron, in this case by a factor of about 60. Unfortunately, this improvement is also realized at the cost of imposing problems which, at the time of designing the CERN proton synchrotron, seemed formidable.

One restriction concerns the curious behaviour of the machine at an energy called the 'transition energy'. During the momentum oscillations in a synchrotron, particles with greater momentum than the mean value swing out to a radius greater than the mean radius. The revolution time of these particles depends on two factors which work in opposition. Because these particles have a greater momentum than the mean value, their velocity is greater than the mean velocity, and they take a shorter time to complete a revolution than the mean revolution time. On the other hand, since the radius at which these particles circulate is greater than the mean radius, they have a longer path to go round and this lengthens their revolution time. In an ordinary synchrotron, the 'radius term' is greater than the 'velocity term' and those particles with greater momentum than the mean value always take longer to go round than the mean particles. Due to the momentum compaction in an alternating gradient synchrotron, the radial displacement for a given momentum change is about a factor of 60 less than in a conventional synchrotron, with the result that at low energies, at the beginning of the acceleration cycle, the velocity term is larger than the radius term. However, as the energy increases and the particles approach the velocity of light, the velocity term decreases due to relativistic effects. Consequently, there comes a time in the acceleration cycle of the CERN proton synchrotron when the radius term equals the velocity term. The energy at this time is called the 'transition energy'.

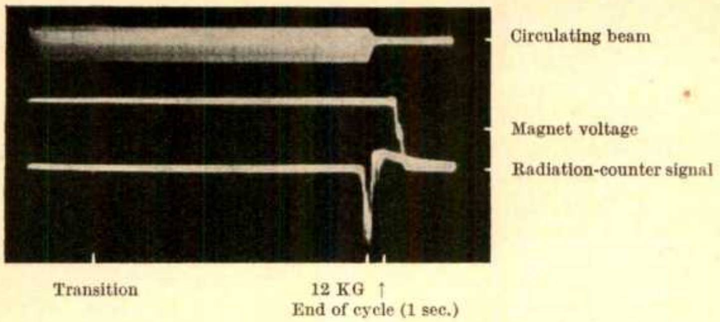

Fig. 2. Beam current versus time. Beam accelerated to about 24 GeV. with no loss

At this energy the frequency of the synchrotron oscillation goes to zero, phase stability is lost, and a rapid shift in the phase of the accelerating voltage has to be made so as to recapture after transition energy all the particles that have been accelerated up to that energy.

It is possible to design an alternating gradient machine so that the transition energy is higher than the maximum energy of the machine, but this can only be done by increasing the circumference of the machine by as much as 50 per cent with a consequent increase in cost. In fact, two new Russian alternating gradient machines have been designed in this way. However, in the case of the CERN proton synchrotron, it was calculated that the transition energy could be passed without loss of particles, and the operational results shown in Fig. 2 justify these calculations. It is possible that the Russian machines will now be modified and consequently will be capable of going to even higher energies.

The particles in a synchrotron circulate at a fixed mean radius, and in order to keep them in the centre of the vacuum chamber during the whole acceleration cycle the frequency of the accelerating voltage must track the steadily increasing magnetic field with high precision. The relative frequency error for a 1-cm. displacement of the mean radius of the circulating particles in the CERN proton synchrotron is given in Table 2.

Table 2

Kinetic energy of protons	$\Delta f/f$ for 1 cm. radial displacement
50 MeV. (injection)	$3 \cdot 5 \times 10^{-3}$
1 GeV.	$8 \cdot 3 \times 10^{-4}$
2 GeV.	$2 \cdot 7 \times 10^{-4}$
3 GeV.	$1 \cdot 2 \times 10^{-4}$
4 GeV.	$4 \cdot 5 \times 10^{-5}$
5 GeV. (transition)	0
10 GeV.	$7 \cdot 0 \times 10^{-5}$
25 GeV.	$7 \cdot 5 \times 10^{-5}$

It can be seen that another unfortunate effect of the transition energy is to impose impossible tolerances on the accelerating voltage frequency at and near that energy. This problem has been solved in the synchrotron in the following manner. From the injection energy of 50 MeV. to about 1 GeV. the accelerating voltage frequency is automatically determined from the magnetic field by an analogue computer having an accuracy of about one part in a thousand. At an energy very much less than 1 GeV., in the 100-MeV. region when the particles are firmly captured in phase-stable bunches, another frequency-controlled system is switched in supplementing the analogue computer. The second system uses pick-up electrodes to detect the phase of the bunches in the machine relative to the phase of the accelerating voltage frequency and, by means of a servo system, holds this phase difference constant at a prescribed value. In addition, the radial position of the circulating bunches of particles in the machine is detected by other pick-up electrodes and, by means of another servo system, the bunches are maintained in the centre of the vacuum chamber.

Apart from these specific problems peculiar to alternating gradient synchrotrons, there are general theoretical problems concerned with non-linear stability criteria which have been studied extensively. The CERN proton synchrotron is equipped with sextupole and octupole lenses to adjust non-linearities in the magnetic field of the machine. A complete description of the CERN proton synchrotron is in course of preparation[3,5,6].

Measurements so far carried out on the CERN proton synchrotron are necessarily preliminary and incomplete. It will take at least six months of measurement work before sufficient is known about the behaviour of the machine to exploit it as a working nuclear physics tool.

The intensity of the proton beam is surprisingly high at this early stage of operation. Protons are injected into the synchrotron at an energy of 50 MeV. from a proton linear accelerator the design of which closely follows that developed at the Lawrence Radiation Laboratory, Berkeley. One important difference, however, is that the CERN proton synchrotron linear accelerator contains magnetic quadrupole alternating gradient focusing in the drift tubes in place of the grid focusing originally used in the American machine. The CERN proton synchrotron linear accelerator has produced intensities up to 5 m.amp. peak although for the tests so far carried out with the synchrotron a collimated 1 m.amp. proton beam has been employed. A buncher and debuncher have been built for this linear accelerator, but neither has been used so far. With 1 m.amp. being injected into the synchrotron and single-turn injection, a capture efficiency of 20–25 per cent has been measured, corresponding to a circulating beam of 10^{10} protons per pulse. The pulse repetition rate at 25 GeV. is 20 per min.

The energy of the protons in the synchrotron has, so far, been calculated from the magnetic field at the time the beam disappears and the radius of the machine. The earliest operational runs were carried out without any of the correcting devices being employed, except for the self-powered pole face windings needed to correct eddy currents in the metal vacuum chamber at injection when the guiding magnetic field is only 140 gauss. The proton beam then disappeared at a magnetic field of about 12 k.gauss due to the number of free oscillations of the particles per revolution becoming an integer. As the magnet yoke becomes saturated, the focusing forces diminish slightly, and instead of the machine working in the stable region between the unstable resonance bands, the operating point is slowly forced into a resonance and the particles are lost to the walls of the vacuum chamber. In later runs the pole face windings were energized by programmed generators designed to keep the focusing forces constant up to magnetic fields of more than 14,000 gauss and it was observed that all the proton beam then reached an energy of just a little more than 28 GeV., limited only by the peak magnetic field available in the CERN proton synchrotron.

An attempt has been made to measure the number of free oscillations per revolution in both the axial and radial directions (Q_V and Q_R) during the acceleration cycle. At injection, with the pulsed inflector voltages not energized and a 2-μsec. pulse of protons injected from the linear accelerator, the beam spirals inwards in radius due to the rising magnetic field for over one hundred microseconds, and the fractional Q-values can be observed in the two directions by pick-up electrodes sensitive to one or the other of the two directions of oscillation. For these measurements the beam is injected in such a way as to set up either axial or radial oscillations of the particles. During the acceleration cycle the Q-values were measured by pulsing the quadrupole correcting lenses at different times in the cycle and by variable amounts, and noting when the beam was lost. The nominal Q-values are both about 6·25, and if at a certain moment the quadrupole lenses are pulsed by an amount that shifts, say, the Q_R value to 6·0, the beam will be lost due to instability at a radial first resonance. Similarly, pulsing the lenses in the opposite direction by the same amount loses the beam due to instability at a radial second-order resonance at $Q_R = 6{\cdot}5$. Apart from the shift of the Q-values when the magnet becomes saturated, it appears that they remain close to $Q_V = 6{\cdot}3$, $Q_R = 6{\cdot}2$ during most of the acceleration cycle. Using this same method, the unstable boundaries of the stable operating region, namely $Q_R = 6{\cdot}0$, $6{\cdot}5$ and $Q_V = 6{\cdot}0$, $6{\cdot}5$, have been measured. So far, no higher-order resonances due to non-linear instabilities have been observed, although whether this is a tribute to the linearity of the machine or due to the crudeness of the measurements remains to be seen.

Measurements have been made of the closed orbit displacement at 20 points around the circumference of the machine, from which the closed orbit amplitude and shape have been computed. The closed orbit is that orbit around which all particles perform free oscillations. In a perfect machine without field-free sectors it would be a perfect circle in a plane. In an imperfect machine its shape and amplitude are due to the imperfections. At injection the peak-to-peak amplitude of the closed orbit in the radial direction is about 4 cm., and in the axial direction it is a few mm. Later on in the cycle the peak-to-peak amplitude diminishes in the radial direction to about 1 cm. and remains negligible in the axial direction. Since the vacuum chamber dimensions are 14 cm. in the radial direction and 7 cm. in the axial direction, there is therefore no danger of loss of beam due to magnet misalignments.

The transition energy, which seemed so formidable a barrier during the design stage, proved to be easily surmountable in practice. The precision of phase switching needed at transition for no noticeable loss of particles was found to be about ± 3 msec., or ± 36 gauss.

Both the computer and the beam control system for determining the frequency of the accelerating voltage have proved very satisfactory after minor adjustments. During the operational runs so far carried out the beam control system has been switched in about 1 msec. after injection and there seems to be no noticeable loss of particles during this switch-over. During the early acceleration studies the radial control servo acted on the amplitude of the accelerating voltage, which in principle is equally effective a means of controlling the radial position of the beam as varying the phase or frequency of the accelerating voltage. This arrangement was not successful, perhaps due to a certain amount of jitter in the phase-lock loop, and the system was modified so that the radial control servo acted on the phase of the accelerating voltage. This second method was completely successful and no particles were lost during acceleration. Preliminary measurements indicated that the beam was not moving more than 1 cm. from the centre of the vacuum chamber during the acceleration cycle. The beam control system depends for its operation on the presence of a bunched proton beam, and due to noise in the servo loops there is a certain minimum value for the circulating beam current below which the system no longer maintains control. It appears from early measurements that the system will work with about 10^8 protons per pulse.

Table 3

Accelerator	Max. energy (GeV)	Mean intensity (particles per sec.)	Completion date
Brookhaven proton synchrotron (Cosmotron)	3	2×10^{10}	1952
Saclay proton synchrotron (Saturne)	3	10^{10}	1958
Princeton–Pennsylvania proton synchrotron	3	2×10^{11}*	1960

Russian A.G. proton synchrotron	50	$\sim 10^{9}$*	1961/62

* Target figures.

A very important parameter of an accelerator is the mean intensity. Table 3 shows that at an energy of 6 GeV. the mean intensity of the CERN proton synchrotron is now nearly as high as that of the bevatron, and at 10 GeV. considerably higher than that of the Russian machine. It is hoped to increase the intensity of the CERN proton synchrotron by an order of magnitude by bringing into operation the buncher and debuncher of the linear accelerator and allowing more protons to be injected into the synchrotron. At 25 GeV. the yield of secondary particles from internal targets is considerably higher than at 6–10 GeV., and early measurements of secondary particle yields from the synchrotron indicate that the machine may be a strong competitor to the lower-energy high-intensity machines now being built from this point of view.

The significance of this accelerating machine can best be understood in relation to other proton synchrotrons. The CERN proton synchrotron accelerates protons to an energy which is about three times the energy of the largest accelerator now functioning, namely the Russian synchrophasotron

Table 4

	Maximum energy	Cost in million (Swiss francs)
CERN proton synchrotron	28 GeV.	120
Rutherford Laboratory proton synchrotron	7 GeV.	84
Saclay proton synchrotron	3 GeV.	53
Hamburg electron synchrotron	6 GeV.	60

at Dubna, and so, for a while, Europe possesses by far the largest accelerator in the world. In 1960 another machine of slightly higher energy (30 GeV.) will come into operation at Brookhaven in the United States, and in 1962 or thereabouts the Russians plan to bring into operation a machine twice as large as the CERN proton synchrotron (50 GeV.). The possession of the world's highest-energy accelerator is, and always has been, a transitory state, but the remarkable significance of this event is that for the first time for more than twenty years Europe can claim this possession. Since the War a major effort has been made in Europe to equip laboratories working in high-energy nuclear physics research with the necessary apparatus. The magnitude of this effort in terms of money is considerable, as can be seen in Table 4.

The cost of running these laboratories and building apparatus for the experiments is equally high, and this is a recurrent cost since new experimental apparatus is continuously being needed as the experiments develop. For example, the annual budget of CERN, which in addition to the CERN proton synchrotron also has a 600-MeV. synchro-cyclotron, is about 60 million Swiss francs per annum.

That Europe has made such an effort in this field of fundamental research has been due to the foresight of the physicists who have planned the laboratories and the sympathy of the national treasuries which have supplied the money.

HUMAN ADAPTATION TO COLD

By Dr. LAURENCE IRVING

Arctic Health Research Center, U.S. Public Health Service, Anchorage, Alaska

THE people from whom we have gained our opinions about physiological reactions to cold have lived in clothing manufactured to common standards and in shelter of regulated warmth. Until recently physiologists have not been impressed by the significance of man's adaptability to cold. But we seem to forget that in every military campaign some soldiers have learned to perform well during prolonged exposure to cold which would have been unbearable in light clothing and poor shelter unless they had developed the adaptability that remains latent without training.

Recognizing this, Scholander *et al.* started expeditionary physiological studies of populations motivated and trained for exposure, including young Norwegians briefly trained in the cold[1] and three different ethnic groups; Arctic Lapps[2], Australian Aborigines[3] and arctic Athabaskan Indians[4]. The results have demonstrated an unexpected range and variety of reaction to cold among people living in cold or chilly climates.

If development of adaptation to cold is associated in our minds with inability to obtain what we regard to be proper protection, we would disregard the many religious individuals and others that have elected to go in thin clothing with bare feet to practise humility and escape from the distraction caused by indulgence for bodily comfort.

The Alaskan members of the Wisdom, Knowledge, Faith, Love Fountain of the World commonly wear only a cotton robe and go with heads, hands and feet bare. They keep their clothing light out of regard for simplicity; but it is their opinion that their garb is more comfortable than the designs of fashion. They avoid endangering themselves by their light clothing, for when the ground is too stony they put on shoes and they add further protection in severe cold weather.

Two young men, students at the University of Alaska, who have been members of the Fount at Venta, Alaska, for about two years, co-operated in measurements of their skin temperature. One of the students, *B*, stood for 64 min. in a room at an air temperature about 0° C., barefoot on a wood floor at − 1° C. to + 1° C., clad in shorts with a loose short-sleeved cotton robe. Towards the end he began to shiver slightly and at 42 min. the side of one big toe had cooled to 7·9° C., thereafter warming to 18·5° C. at 53 min. and cooling again to 15° C. at 64 min. At 17 min., when he remarked feeling both big toes warming, the recorded temperature on one toe had risen from a momentary low at 10·0° to 10·2° C. in the preceding minute and rose in the next minute to 10·4° C. At 34 min. the big toe had cooled again to 8·8° C., a change that he also reported as it began. At 42 min., when the toe was 7·9° C., it felt uncomfortable but not painful. 30 sec. later, when the toe had warmed to 8·6° C., he had already informed me of the warming. His body felt uncomfortably chilly, and he directed attention to sweating in the armpits which he said often accompanied reaction to chill.

The second student, *G*, stood in the cold room (air 1° C. to 2° C., floor − 2° C. to − 3° C.) for 34 min. His big toe cooled to 4·9° C. in 20 min. and to 4·6° C. in 34 min. At 20 min. his legs shivered in vigorous,

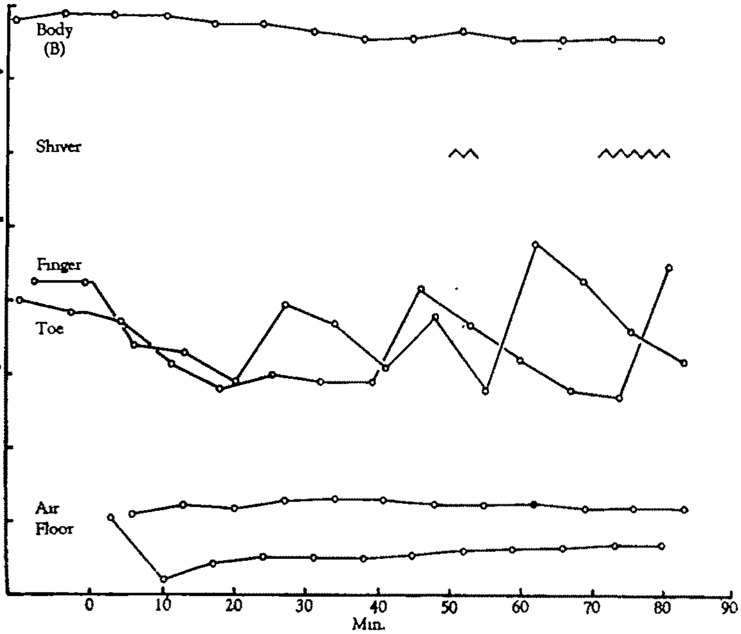

Fig. 1. Record of skin temperature in student *B*. Note the large swing of temperature in fingers and toes and the very slight shivering

intermittent bouts and he reported that his body felt warm and that his feet were not painfully cold. The test was not terminated by cold but owing to dizziness from standing.

On a second occasion, temperatures were recorded with the students sitting reading in the cold room, dressed as before. The record in Fig. 1 is for student *B*, and shows the average reading from two thermocouples on the back and one on the sternum (the three not differing more than 1·5° C.), one on the mid-finger pad and one on the big toe near the base of the nail. The tip of the middle toe held within 2° C. of the big toe. The outer side of the foot 2 cm. from the base of the little toe and the dorsum were about 10° C. warmer than the toes. Legs were intermediate between the temperatures of the body and feet.

The finger of student *B* began to warm and cool in long cycles after 20 min. (Fig. 1), his toes warmed at 40 min., and their warming at 60 min. was asynchronous with the warming of the finger. Student *G*, who shivered somewhat more but not vigorously, showed no clear-cut warming of the toes but a distinct warming of the finger. Although his toes were colder than 5° C. from time 65 to 100 min. they were not painful. The reactions to painful cold are usually so evident that it is unlikely that they could be deliberately suppressed and the students located and described their other sensations very accurately. Both students said that although they would not choose such conditions for study the cold did not interfere with their reading. Airman Henson, who assisted in the observations, and I were chilly in warm clothing as we moved in and out of the cold room.

A contrasting response was shown by the airman, who had been in Alaska for about two years. Sitting with bare head, hands and feet, and wearing only cotton fatigue jacket and trousers over shorts, about equivalent in insulation to the robes of the two students, his fingers and toes did not cool quite so low as those of the students (Fig. 2). He began shivering almost at once and continued in violent intermittent bouts which soon reached disagreeable intensity. After 8 min. his toes felt very uncomfortable and were very painful after 14 min. At 41 min. it was considered that his fortitude was not contributing further to physiology, and he reluctantly consented to terminate the test.

In spite of his shivering, which perhaps cooled him by ventilating his clothing as much as it contributed in metabolic heat, the airman's body skin cooled promptly. The two students had kept their bodies comfortably warm with but little shivering. As student *G*'s toes cooled to about 5° C. at 65 min., he remarked that they lost sensation and he could not detect a light touch with a pencil. The feet of all subjects were flushed and somewhat swollen, blanched on pressure and on release immediately reddened again. Spontaneous blanching of the feet was not observed, and judging by this criterion frost-bite was not imminent. After leaving the cold room the students re-warmed promptly with no pain; the airman took about 15 min. to regain comfortable warmth, with diminishing pain as recovery proceeded.

Although one of the students lost sensitivity in his toes when they cooled to about 5° C., otherwise both of them acutely observed their sensations of cold and warmth and located them with surprising accuracy, which surprised me and the airman. The students reported and located warming of even one toe by a fraction of a degree and accurately named the cessation of the warming phase of the cycles.

Student *B* pointed out that visible beads of sweat formed on his finger tips as they began to warm and showed me sweat beads on his warming toes after the tape covering the thermocouples was removed.

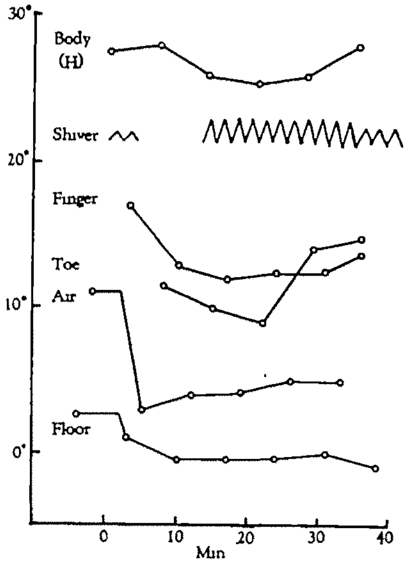

Fig. 2. Records of skin temperature in Airman Henson. Violent shivering with considerable fall of surface temperature

The airman also pointed out sweat on his still painfully cold toe as it warmed after the thermocouple was removed. Localized sweating thus appears to be connected with the vascular reaction which brings about warming of cold skin. It appears that local re-warming is associated with sweating. Sweating seems inconsistent with very cold skin; but the surprising combination may furnish a clue to the nervous component involved in peripheral regulation of temperature.

These adapted individuals appeared to have developed accurate appreciation for the temperature of their skin, keeping track of the changes at various locations at all temperatures down to about 6° C. They apparently deliberately utilize this conscious scanning of the thermal situation to avoid unsafe exposure. Eskimos also observe and care for the thermal situation in their faces and hands in extreme cold, and rarely experience frost-bite except through accident or when required by circumstances deliberately to tolerate the well-known sensations which warn of incipient frost-bite.

The freedom of the adapted men from pain caused by cold was associated with retention of adequate sensitivity and probably with improvement in the recognition of temperature of skin, its small changes and exact location. Keen appreciation of thermal conditions must be employed for the maintenance of skin to be safe at temperatures critically close to freezing, for, like hibernating animals, very cold tissues lack heat and the power for its production which buffer warm tissues against the fatal consequences of small depressions in temperature. I have remarked that sensitivity persists in the very cold feet of arctic birds and mammals which are still accurately guided by the sensations requisite for standing and movement[5]. Only sensitive feet can safely serve to economize on heat by cooling to nearly freezing, and it is obvious that insensitive tissues could perform no adaptive function.

It is also essential that any surface of an animal normally making contact with cold snow or ice should not become warm enough to cause melting or the skin or hairs would quickly freeze fast[6]. The students said that when they stepped from a warm room on to cold icy ground their feet became iced and picked up gravel, causing painful abrasions, although if icing did not occur their feet could withstand even − 20° C. for a time. Those who have hunted with dogs in cold snow will recall that the feet of some kinds become crippled by icing. The feet of healthy arctic animals do not commonly become iced as long as they are free to care for themselves.

After habitually wearing shoes, learning to walk with bare feet on rough ground involves some superficial hardening, but the process of learning to utilize the latent adaptability also involves improvement in operation of the senses which must direct the bare feet so that they are guided to avoid violent contacts with sharp or hard objects which no living tissue could withstand. In cold-adapted feet it is evident that the temperature causing cold pain is lowered, but sensitivity to temperature and the other senses necessary for the use of the feet must remain adequate for their effective operation.

These two students have deliberately practised exposure to cold in Alaska for only two years, but their exposure was less frequent and severe than among some of their people who worked out of doors. The airman appraised the practical importance of their adaptation by remarking on the advantageous mobility that would be gained by an infantry battalion trained to operate in such light clothing; but when I remarked that airmen would gain equally if relieved from some of the impediments of clothing and shelter he was less pleased with the idea.

It is apparent that human adaptability to cold is of practical importance when it is evoked by careful training motivated by consideration of benefit to be obtained from exposure. It is also apparent that adaptability to cold remains a latent faculty in urban populations.

Dr. Raymond J. Hock made instruments available from the Arctic Aeromedical Laboratory, and generously helped with preparations and part of the observations. His assistant, Airman First Class Harns C. Henson, of the Arctic Aeromedical Laboratory, gave skilled help throughout the experiments.

COMMITTEE ON NATURAL RESOURCES IN SCOTLAND

By Dr. F. N. WOODWARD, C.B.E.

Arthur D. Little Research Institute, Inveresk, Midlothian

A COMMITTEE on Natural Resources in Scotland has been set up by the Scottish Council (Development and Industry) under the chairmanship of Mr. L. A. Elgood to examine the most suitable ways of developing and conserving Scottish primary resources. At the outset, two stages are envisaged: first, the setting-up of a fact-finding study group to provide information and, secondly, a subsequent conference of wider educational scope with emphasis on socio-economic problems.

The study group, which will meet at the Royal Society of Edinburgh during October 31–November 2, will comprise about fifty invited national and international experts in the various resource fields, who will discuss and review previously prepared papers designed to cover these problems in three phases, namely, individual resources already surveyed, the inter-relationship between them, and resource administration techniques and development.

The published proceedings of this fact-finding study group will not only make available to the public for the first time an up-to-date assessment of Scotland's primary resources, but also provide the background information for the subsequent more comprehensive conference which is intended for a larger, less technical audience, and would be designed to influence public opinion.

It is anticipated that the complete inquiry will cover a period of 3–4 years and inevitably lead to a change in the public's attitude towards problems of resources.

While it is not possible to anticipate the outcome, it is envisaged that the need for additional research institutions and for a permanent centre for information and for the co-ordination of the interests and efforts of those concerned with conservation and use of resources will emerge.

The setting up of the Committee on Natural Resources in Scotland is a logical if belated outcome of the United Nations Scientific Conference on the Conservation and Utilization of Resources which was held at the United Nations temporary headquarters at Lake Success in 1949. That Conference was unique among international conferences in that it provided a forum for more than six hundred scientists, conservationists and economists concerned with assessment, conservation and development of resources, drawn from fifty different countries. Their deliberations, in which the large British and Commonwealth delegation under the leadership of Sir Harold Hartley took an active part, in the presence of 350 observers resulted, among other things, in the production of seven volumes of "Proceedings" which are now recognized as the classic reference authority on world resources.

Among many suggestions emanating from the Conference was one to the effect that all countries should be regarded as under-developed, and that their known and potential primary resources should be examined afresh. This has been followed by resource surveys and conferences in various parts of the world. In the United Kingdom, however, there has been no comprehensive conference to follow the example set by the United Nations Conference. There are many reasons why such a conference would be difficult to organize, and even if it were, the outcome would be of debatable value ; but Scotland, on the other hand, presents a sufficiently compact region and has, at the same time, the diversity of resources to yield good results from such an inquiry. These resources are soil, water, minerals, fuel, fish and wild-life, forestry, and people of particularly interesting character.

A persistent problem in regard to the last of these is the continuous drainage of Scottish people through emigration. At present, about 40 per cent of Scottish graduates in science, and 60 per cent in engineering, leave to work elsewhere. While there are many examples of a flow in the reverse direction, the overall loss by emigration of trained men is too high and is a matter for serious concern.

There are other obvious resource problems awaiting solution in Scotland, and many more will doubtless be revealed as the inquiry develops.

For example, peat covers 1·7 million acres of land : if technical problems now under investigation by the Scottish Peat Committee are solved, a new industry could be established using an indigenous natural resource, with coincidental land reclamation for productive use. The conflict between agriculture, forestry and local authorities for land-use is being energetically tackled by the Scottish Departments and others : the attack on ancillary problems—such as the infestation by bracken of more than 0·5 million acres of land and the industrial use of agricultural crops and by-products—on the other hand, has been sporadic and frequently uninspired.

Although the demand for water is increasing rapidly, no single agency exists to survey and regulate water resources. There is a lack of hydrometric and underground water data and no standard technique for river flow gauging.

Also, although Scotland is very well surveyed geologically, very few geophysical surveys have been undertaken and no facilities exist for mineral beneficiation, research and development.

Due to historical trends, certain of the British natural resources agencies operate entirely within the Scottish regional context, whereas others have an overall United Kingdom interest. For example, fuel supply and forestry are dealt with on a United Kingdom basis, whereas agriculture is administered from a central Scottish headquarters ; water is not the concern of any particular agency.

Scotland's natural resource endowments, although significant, are relatively limited in number. Some of these, such as coal, oil-bearing shale, and water for hydro-electric power, have already been exploited, and others can, through research, form a source of wealth in the future.

In this respect, Scotland is handicapped in that its Government-supported resource laboratories, besides being small in number, are in imbalance. Though there are eleven concerned basically with the use of soil for agriculture, not one is solely devoted to forestry. The only other primary resource laboratories in Scotland are those dealing with fish, jute, peat, coal and nature conservancy ; none, for example, is available for undertaking research on mineral beneficiation, non-fish marine resources or chemurgy.

A good example of primary resource development is to be found in the new seaweed-based industry in Scotland which resulted from the co-operation between industry and an independent research organization specifically set up for the purpose.

Quite apart from the lead given by the United Nations Conference, it has been felt for some time that a new and integrated study of Scottish resources —including man—should be undertaken on the widest possible scale.

It is realized, of course, that such inquiry could result in recommendations which might affect certain present-day economic interests, although the ultimate result would be in the national interest.

The immediate use of peat for fuel, for example, might conceivably react to the detriment of future generations whose need for peat for water-storage purposes might be more vital. On the other hand, the locking of certain resources would not necessarily be a good thing, since unforeseeable changes, resulting from advances in scientific knowledge, could in the future make such action futile.

It is the hope of its promoters, however, that, among other things, the inquiry may be instrumental in preventing development of one resource from permanently damaging another, and thus avoid the chaos which has resulted in many parts of the world from haphazard and unco-ordinated development.

The Secretary of the Committee on Natural Resources in Scotland is Mr. H. M. Wilson, The Scottish Council (Development and Industry), Edinburgh.

OBITUARIES

Prof. Eric S. Horning

On November 14, 1959, British cancer research lost one of its prominent figures by the death of Dr. E. S. Horning, professor of experimental pathology in the University of London at the Chester Beatty Research Institute. Australian by birth, he served as a volunteer with the Imperial Forces during the First World War, and went to Oxford in 1920 to start his professional career in the honours school of comparative anatomy and zoology.

Having taken his degree, he went into research, first in Melbourne with Prof. Agar and later with A. Fischer in Berlin-Dahlem and E. V. Cowdry and A. Carrel in the United States. From this period stem numerous papers dealing with the behaviour of mitochondria and other cytological problems. The excellence of his early work was soon recognized. In 1932 he contributed by invitation an article on the enzymatic function of mitochondria to "Ergebnisse der Enzymforschung", and in 1941 he wrote in G. Bourne: "Cytology and Cell Physiology" the chapter on micro-incineration and the inorganic constituents of cells, a subject on which he was an authority.

Armed with a comprehensive knowledge of cytology and histology, and well versed in the methods of tissue culture, in 1933 he returned to England, the country he loved more than any other, where he spent the rest of his life but for the years of the Second World War, during which he served again with great distinction in the Armed Forces.

In 1933 Dr. Horning joined the staff of the Imperial Cancer Research Fund as a Beit Fellow; when six years later the outbreak of war called him from the bench he had made his name as a cancer investigator. A series of brilliant papers had appeared in which Cramer and Horning recorded their original observations, shedding new light on the pathogenesis of the tumours of the breast, pituitary and thymus, and establishing the role of the adrenals in the development of these tumours.

In 1947 Dr. Horning accepted an invitation by Prof. A. Haddow to go to the Chester Beatty Research Institute as reader in experimental pathology. There he worked until the end, his scientific activities continuing unabated in spite of periods of indifferent health. Testimony to his persistent interest in the endocrinological aspects of cancer are the chapters in "Oestrogens and Neoplasia", his contribution to "Causation of Cancer" in the *British Medical Bulletin* 1958, and his papers on the experimental cancers of the prostate and the œstrogen-induced tumours of the kidney. Although from 1936 onward the role of hormones in neoplasia was the main theme of his endeavours, by his studies of the action of carcinogenic compounds on grafted tissues he made notable contributions to chemical carcinogenesis. Besides, his considerable experience with the pathology of the experimental and spontaneous tumours of rodents made him an invaluable collaborator in many projects of the Chester Beatty Research Institute. *Inter alia,* he described with Boyland the tumours induced by nitrogen mustards in mice, and with Alexander the reaction of the subcutaneous tissue of the rat to implanted plastic films.

Anybody who had the privilege to visit Dr. Horning in his laboratory and to look at some of his slides could only admire the beauty of his histological preparations, and was no longer astonished by the excellence of the photomicrographs which adorn his papers. The high quality of the material on which Dr. Horning's results were based and the elegance of his techniques rather than ingenuity of speculation were the basis of the high esteem he enjoyed among his colleagues at home and abroad. But, above all, few men had his gift for friendship and a heart so warm and generous. Only those who have worked with him know how easy he made life for his collaborators and how much he did unselfishly to further the work of the Institute. For his human and scientific qualities the memory of Eric Horning will be cherished in many lands.

F. Bielschowsky

Mr. W. E. Dick

With the sudden death of William E. Dick at the early age of forty-five, scientific journalism has lost one of the greatest exponents of this now rapidly expanding and increasingly important field—a field which shows signs of becoming to-day almost as important to the scientist, as a means of keeping him informed of developments in other fields as well as his own, as to the intelligent layman who wishes to learn about scientific and technological progress. He was successively editor of *Discovery* (1945–56), *British Chemical Engineering* (1956–58), and *Chemistry and Industry,* the journal of the Society of Chemistry and Industry. Prior to that he had held posts on the *Grantham Journal* (1941) and the *South Western Star*, which he joined in 1942. For a brief period he then worked as assistant editor to *Chemical Age*, before joining *Discovery* in a full-time capacity in September 1944.

William Dick was born at Walthamstow on July 12, 1914, and was educated at King's School, Wimbledon, where he took a State scholarship at the age of fifteen to the Imperial College of Science and Technology to read biology. Although he left the Imperial College before his degree was completed, his training was not purely journalistic, for he later became a qualified scientist, taking an external B.Sc. degree at the Chelsea Polytechnic in 1942. He was also elected a Fellow of the Linnean Society.

During the War he served with the Auxiliary Fire Service during the first months, and then at the British Expeditionary Force, Royal Army Service Corps Headquarters in France before being evacuated when France surrendered. Then he transferred to one of the camouflage units of the Royal Engineers at Farnham. He entered journalism in August 1941, after being invalided out from the Army.

When Bill Dick became editor of the newly revived *Discovery*, science writing was still, as I was made only too well aware on numerous occasions, regarded as a 'bastard art', more often than not despised by the scientist and badly handled by the Press. By setting a standard of journalistic and scientific reporting that raised *Discovery* from being a relatively unknown journal to one that had a readership throughout the world, and was renowned and highly regarded as a scientific paper, Dick showed and taught others that science writing could be a valued and respected branch of science. In the process he also not merely set a new standard for other people to follow, but also helped to give invaluable advice and training to many new-comers venturing into this field. Besides his activities as editor for *Discovery*, Dick also wrote many articles, one of the best known of which was "Science and the Press", which was written in 1954 for the journal *Impact*. Here he set out many of the problems he had encountered and the ideals in which he believed. He also wrote, or contributed to, a number of books as, for example, "Science and the Welfare of Mankind", written in conjunction with I. B. N. Evans, published by Simpkin Marshall in 1946, and "The Story of Energy", published in 1951 for the Bureau of Current Affairs. In 1957, Butterworths Scientific Publications brought out his "Atomic Energy in Agriculture".

Dick's interests, indeed, were catholic in the extreme, every field of science intrigued and on occasion excited him, although professionally by qualification he was a biologist. The latter fact explains perhaps to some degree his immense interest in flowering plants and the joy and enthusiasm which he brought to his gardening.

Despite his many achievements, William Dick suffered for twenty years from a long series of illnesses of increasing severity. The debt owed him by scientific journalism is immense, and his early passing is an occasion of great sadness. Personally, also, he will be missed as one of the kindest and most generous of people, especially in times of trouble.

DEREK WRAGGE MORLEY

IT is impossible to conceive of any scientist, certainly of any editor or journalist, who was not shocked by the news of Bill Dick's sudden death or who will not now miss his entertaining chatter and stimulating pronouncements on science, especially on the exposition of science.

Although he was initially a reporting journalist and eventually an editor, he was never satisfied merely to sit down and rewrite into more readable form scientific reports and research publications which came to hand. He really believed that the good editor wears out the soles of his shoes rather than the seat of his pants. He went after news personally and wrote it up personally. For this reason alone, it is true that as Mr. Wragge Morley writes: "*Discovery* [metamorphosed] from being a relatively unknown journal to one that had a readership throughout the world, and was renowned and highly regarded as a scientific paper". Though *Discovery* still maintains this excellent standard, I am sure the present editor would be the first to admit that this happy editorial evolution was originally inspired by Bill Dick.

Dick's remarkable achievements and his engaging, though somewhat naïve, personality did not pass unnoticed, especially among his journalistic and editorial colleagues. For example, 1956 saw the tenth anniversary of the new *Discovery* which coincided with the tenth anniversary of Bill Dick's editorship. To mark this double event, a sherry party was held to which only editors and science writers were invited. It was significant that everybody who had been invited attended to pay tribute to Dick and *Discovery*.

Bill had a warm heart and a ready tongue. He had a real gift for nosing out news. His sincerity could never be challenged, for if he admired a person or his achievements he was lavish with praise; but woe betide anybody who, in his opinion, was not playing the game. You always knew how you stood with Bill.

It is a tragedy that science and especially the exposition of science (mainly through popular publications) has now to suffer the loss of this remarkable man; for science still suffers from a dearth of good writers, in spite of the fact that, as Mr. Wragge Morley says: "Science writing [is] a valued and respected branch of science".

The presentation of scientific advancements and achievements in an understandable form has now become an essential branch of science itself. Research cannot go on indefinitely behind closed doors; there must eventually be a fearless exposition and interpretation of the truths it unfolds. Bill Dick believed this and worked selflessly and passionately to this end.

L. J. F. BRIMBLE

Dr. H. P. Wilkins

HUGH PERCIVAL WILKINS, the distinguished selenographer, died at his home at Bexleyheath, in Kent, on January 23.

Wilkins was never a professional astronomer. He was born and educated in Carmarthen, and after serving in the Army during the First World War he became an engineer. His main interest lay, however, in astronomy. Though he made useful planetary observations from time to time, he concentrated almost entirely upon the Moon, and by 1924 had completed a lunar map 60 in. in diameter. Eight years later he commenced work upon an even larger chart, to a scale of 300 in. to the Moon's diameter. A prodigious amount of work went into this project; except during occasional periods of ill-health, Wilkins was nearly always busy at his telescope whenever the sky was clear and the Moon visible. The 300-in. map was published in 1951, and he then undertook a further revision, which appeared in 1954. Yet another revision was planned, though unfortunately he did not live to complete it.

After his marriage, Wilkins moved from Wales to Kent, and set up a 12½-in. reflector, later replaced by a 15¼-in. instrument. It was with this equipment that he carried out most of his work, though he also made numerous observations with very large instruments in both Europe and the United States. He was a regular contributor to many scientific periodicals, and held the position of director of the Lunar Section of the British Astronomical Association from 1946 until his resignation ten years later. In 1941 he gave up practical engineering, and joined the Ministry of Supply, retiring only at the end of 1959 with the intention of spending the last part of his life in astronomical work.

Wilkins was well known as a lecturer on astronomy; he made frequent broadcasts on both sound radio and television, and was the author of seven books, the last of which was completed only a few days before his death. In 1955 the University of Barcelona conferred on him an honorary Ph.D. degree in recognition of his work for selenography.

Wilkins was above all a kindly man; he was unfailingly courteous, and could never understand those who were not. His enthusiasm for astronomy was inspiring, and he was always ready to help others. A deep sense of personal loss will be felt by his many friends all over the world.

PATRICK MOORE

NEWS and VIEWS

Chemical Engineering at Swansea : Prof. E. S. Sellers

Prof. E. S. Sellers resigned his post as head of the Department of Chemical Engineering, University College of Swansea, on January 31, to join the British Petroleum Co. as manager of the Petroleum Division at the Sunbury Research Centre. When in 1955 Prof. Sellers went to Swansea from the Department of Chemical Engineering, University of Cambridge, he faced the task of building a new department in a College that planned unusually rapid extension to its facilities for education in applied science. He leaves a department of chemical engineering with a well-established teaching programme that makes provision for the admission of some thirty honours students annually and the expectation of expansion to an entry of fifty students when new accommodation becomes available during the next five years. A special feature of the course for chemical engineers in Swansea has been the more than usual involvement of local industry. A considerable part of the practical work for undergraduates has been carried out on industrial plant rather than on laboratory equipment in the Department. This has been made possible by the excellent relations that the Department of Chemical Engineering has established with industry. During his period in Swansea, Prof. Sellers has supervised research on the flow of non-Newtonian liquids and the control of continuously operating process plants. In 1957 he was awarded the Moulton Medal of the Institute of Chemical Engineers for work (with Dr. D. R. Augood) on the distillation of hydrogen. He has served the Institution of Chemical Engineers as a member of the Council and on the Board of Examiners. He has been a member of several advisory committees of the Admiralty and the Ministry of Supply.

Prof. J. F. Richardson

Prof. J. F. Richardson, who succeeds Prof. E. S. Sellers at Swansea, graduated at the Imperial College of Science and Technology in 1941. After six years of postgraduate research with Sir Alfred Egerton, he was appointed lecturer and later senior lecturer at the College. In 1958 he resigned his university appointment to join the Development Division of Messrs. A. Boake Roberts and Co., Ltd., as senior chemical engineer. Prof. Richardson has served the Institution of Chemical Engineers for four years as a member of the Board of Examiners, as honorary librarian since 1954, and as a member of the Nominations Committee, the Careers Advisory Committee and the Advisory Panel on student membership. His publications cover a wide range and include a text-book on chemical engineering written jointly with Prof. J. M. Coulson. During 1941–47 his work was largely concerned with laboratory and large-scale studies on fire prevention and extinction. More recent research by Prof. Richardson has related to the physical properties of two-phase systems.

Royal Naval Scientific Service : Mr. J. Buckingham, C.B.

Mr. John Buckingham, who recently retired from the Royal Naval Scientific Service, where he held the post of director of research programmes and planning, joined that Department as a technical assistant in the Board of Invention and Research in 1917 and made naval science his career. During the years between the Wars he played an important part in the development of what was ultimately to become the Royal Naval Scientific Service. He was the assistant and confidant of the first director of scientific research, Dr. (later Sir) Frank Smith, and of his successors. The last of these, Mr. (later Sir) Charles Wright, selected him in 1936 as his deputy, a post he filled for ten years. In 1946 he was appointed the first director of research programmes and planning, with special responsibility for the management of peace-time research and development expenditure. Successive controllers of the Navy have spoken warmly of the skill with which these duties were carried out. He served on various Admiralty committees and represented the Admiralty on outside committees, always with distinction. His valuable advice was sought officially and unofficially by high and low on almost any matter which was 'tricky', and what he did behind the scenes often determined the success of actions in which officially he took no part. His many important works were recognized in 1953 by the award of the C.B.

Dr. W. E. Pretty

With the retirement of Mr. Buckingham, the Department of Research Programmes and Planning has been absorbed into a new Department of Research and Development Services ; Dr. W. E. Pretty has been appointed to be its first director. As a Royal Scholar, Dr. Pretty was awarded the A.R.C.S. and the Governors' Prize in physics at the Imperial College of Science and Technology in 1925, and in the same year took his B.Sc. (first-class honours), London. For the next six years his time was spent between teaching and research at the College under Prof. A. Fowler. His researches in spectroscopy gained him his Ph.D. degree. In 1931 he joined the Science Museum as assistant keeper in charge of the optics and the astronomy collections. He served as secretary to the Advisory Council of the Museum and was much concerned with the successful introduction of a new type of 'special exhibition' showing really up-to-date science and technology in a particular field. In 1939 he was seconded to the Admiralty Department of Scientific Research and at the end of the War accepted an invitation for permanent transfer to the newly formed Royal Naval Scientific Service. He was promoted to the rank of deputy chief scientific officer and appointed director of research programmes and planning in 1948.

Toxic Chemicals in Agriculture

The Minister of Agriculture, Fisheries and Food, with the Minister for Science, the Secretary of State for Scotland and the Minister of Health, have appointed the following Research Study Group to consider this subject : Prof. H. G. Sanders, chief scientific adviser (agriculture), Ministry of Agriculture, Fisheries and Food (*chairman*) ; Dr. H. R. Barnell, chief scientific adviser (food), Ministry of

Agriculture, Fisheries and Food; Dr. J. M. Barnes, director, Toxicology Research Unit, Medical Research Council; Prof. A. R. Clapham, professor of botany, University of Sheffield; Dr. R. A. E. Galley, director, Tropical Products Institute, Colonial Office (officer-in-charge, Colonial Pesticides Research); Mr. C. O. Harvey, Laboratory of the Government Chemist (Department of Scientific and Industrial Research); Dr. Donald Hunter (physician to the London Hospital and part-time physician-in-charge, Department of Research in Industrial Medicine, London Hospital); Mr. W. C. Moore, director, Plant Pathology Laboratory, Ministry of Agriculture, Fisheries and Food; Prof. W. L. M. Perry, professor of materia medica, University of Edinburgh; Mr. G. G. Samuel, scientific staff (headquarters), Agricultural Research Council. The terms of reference for the Group are: "To study the need for further research into the effects of the use of toxic chemicals in agriculture and food storage, and to make recommendations". The Group is independent of the interdepartmental Advisory Committee on Poisonous Substances used in Agriculture and Food Storage, which will continue.

Corrosion Science Society

THE Corrosion Science Society has been founded with the following immediate aims: (1) to promote the advance of corrosion science and its application to the solution of practical problems; (2) to organize meetings—personal, local, national and international—of scientifically qualified persons interested in all fields of corrosion and corrosion-protection research and practice, for the discussion of current work; (3) to co-operate with all other professional individuals, societies and institutes, British and foreign, with interests in the corrosion field. The first meeting will be held during April 4–5 at the Battersea College of Technology, London. Stress-corrosion, cracking, the corrosion and protection of aluminium, cathodic protection, electrode processes and high-temperature corrosion and oxidation will be among subjects to be discussed on the basis of a series of talks by workers at present active in these fields, including C. Edeleanu, J. G. Hines, T. P. Hoar, J. E. O. Mayne, N. F. Mott, E. C. Potter and L. L. Shreir. Those interested should write to either Dr. T. P. Hoar, Department of Metallurgy, Pembroke Street, Cambridge, or Dr. L. L. Shreir, Battersea College of Technology, London, S.W.11.

Research in the German Federal Republic

ON behalf of the Federal Republic, the German Embassy in London publishes quarterly an attractive journal, *Germany*. A recent issue was devoted to fundamental research and its application (4, No. 12; 1959). The main articles deal with plastics and their place in the German economy together with accounts of the work being carried out in the different plastic research institutes. Prof. Curt Hoffmann, of the Institute of Oceanography, Kiel, is the author of an essay on marine production biology, and Prof. K. O. Kiepenheuer, of Freiburg, describes solar research in Germany. To inaugurate a series of portraits of German Nobel Prize winners, there is an illustrated account of the life and work of Prof. Otto Kahn. The journal also contains articles describing various aspects of cultural life in Germany, the most interesting portraying celebrations in connexion with the Schiller bicentenary in West Germany. The annual subscription to the journal is D.M. 20.

The Burma Research Society

DURING 1910 a small group of Burma residents, mostly Civil servants with varied interests as amateurs in the natural history, archæology, history and literature of the country, established a society to serve as a forum for their discussions and a *Journal* for the publication of their findings. The creation of the University of Rangoon ten years later brought many well-qualified recruits to the Society and the University gave it a permanent home. The thirty-one volumes of the *Journal* published between 1910 and 1941 include many original papers of first-class importance, but everything came to an end with the Japanese occupation. All records and stocks of publications went on the bonfire of the University Library and very few complete sets of the *Journal* seem to be in existence. The Society started up again in 1948, and it was a happy thought of its 700 members, headed by the president, the Hon. U Chit Thoung, Minister of Culture, to mark the fiftieth anniversary by holding a six-day conference during December 28, 1959–January 2, 1960. Twenty-one papers were read and a further fourteen contributed to be published in a single volume with the conference proceedings. Some fifteen overseas visitors were guests of the Burma Government and were afterwards taken to Pagan, ancient capital of Burma, incredibly rich in archæological and historical treasures, still in course of study by Prof. G. H. Luce and others. At the conference, Britain was represented by Dudley Stamp (professor of geology and geography in the University of Rangoon, 1923–26). To further mark the occasion, the Society is reprinting the more important papers of its pre-war *Journal*. There are to be three volumes—respectively History and Literature (published), Economic and Social, and Science, obtainable from the Society, c/o University Library, Rangoon, at kyats 20 (30*s*.) each. The Science volume includes eight geological papers, and a number on earthworms, tapeworms, algae and agricultural pests. A complete index to the *Journal* is also to be published.

Scientific Societies in the United States

THE U.S. Office of Science Information Service recently distributed a questionnaire to more than two hundred national scientific societies (*Scientific Information News*, 1, No. 4; Aug.–Sept. 1959). The questionnaire is part of a study designed to provide objective information about the human and financial resources of scientific societies and their publications. Data requested by the questionnaire include: (1) total membership and distribution of members among various membership categories; (2) titles, frequency, and subscription rates of society publications; (3) sources of income, including subscriptions and endowments. This study of scientific societies is the first step in a wide-ranging programme designed to provide a clearer picture of scientific communication in the United States. The results of two other National Science Foundation studies—one of the policies, practices and costs of professional scientific journals and the other of scientific man-power data gathered by the National Register of Scientific and Technical Personnel—will be correlated with the scientific society study to help the Office of Science Information Service carry out more effectively its task of fostering co-operation and co-ordination among scientific information sources.

Darwin's "Journal"

IN his "Autobiography", Darwin referred to a "little diary, which I have always kept", in which he recorded the work on which he was engaged, the time which he took in completing each of his researches, the books in which they were described, and his movements from place to place. The document itself was headed "Journal". Francis Darwin also referred to his father's "Diary or Pocket-Book" as having been of great help to him in writing and compiling "Life and Letters". He added that "it was unfortunately written with great brevity, the history of a year being compressed into a page or less, and contains little more than the dates of the principal events of his life, together with entries as to his work, and as to the duration of his more serious illnesses". Some important quotations have been published from the "Journal", such as the famous entry under the date 1837: "In July opened first notebook on 'transmutation of species'. Had been greatly struck from about month of previous March on character of South American fossils, and species on Galapagos Archipelago. These facts origin (especially latter) of all my views". Edited by Sir Gavin de Beer, the "Journal" has now been published as a Bulletin in the Historical Series of the British Museum (Natural History) (2; No. 1). Students of evolution will be grateful to Sir Charles Darwin and the Syndics of the Cambridge University Library for granting permission for this rich chronological story to be published.

Preserving the Amenities of Great Britain

AN interesting example of the zealous way the Council for the Preservation of Rural England safeguards the amenities of Britain is revealed in its report for 1958–59. Its Central Panel Committee has recently considered the implications arising from the fact that the output of pressed Oxford clay bricks is now approaching 50 per cent of the entire production of all bricks in England, Wales and Scotland. Enormous quantities of these bricks are in general use within an area at least as far as 160 miles distant from the main producing area in Bedfordshire. As the appearance of new buildings throughout this area is linked with the type of brick available, the Committee felt that the manufacture of a reasonably wide variety was a matter for which the industry had great responsibility. These views were expressed in a letter to the Pressed Brick Manufacturers' Association. In reply, the Committee was informed that several new varieties are now on the market, and it is hoped that this policy will be promoted by the Association. The recent production of an attractive grey facing brick by the London Brick Co., suitable for use in stone districts such as north Bedfordshire, and adjacent parts of Northamptonshire, is a useful addition to the varieties now available.

Nature Protection in U.S.S.R.

MR. G. ALIEV, of the Academy of Sciences of the Soviet Republic of Azerbaijan, has described the text of a new law for the protection of Nature which was passed in the Republic in June 1959 (International Union for Conservation of Nature and Natural Resources, Bull. 8; Oct. 1959). The Commission for the Protection of Nature of the Academy of Sciences played a leading part in preparing and supporting this law. The Act provides for the conservation of the resources of the inanimate world and of living species, as well as the constitution of nature reserves and partial reserves. The same Act specifically mentions some interdicts: prohibits all economic activity within the reserves which would be contrary to their objectives; all interference with the places and objects preserved; all sale and purchase of reserved territories; all breaches of the hunting and fishing regulations; all uncontrolled introduction of exotic species; as well as undertakings which might result in air or water pollution, or begin or aggravate the process of erosion, the last being a source of grave problems in Azerbaijan. Any violation of the Act is considered a breach of Article 138 of the national constitution, which aims at "protecting and strengthening the sacred and inviolable foundation of the Soviet regime: public and socialist property". The Council of Ministers of the Azerbaijan S.S.R. and certain other Government departments have been charged with a number of duties relating to the protection and restoration of natural resources as well as measures against pollution and erosion; scientific preparation of natural resources of development schemes, recommendations, as well as the spreading of the principles and aims of conservation of Nature.

Liquified Petroleum Gases

LIQUIFIED petroleum gases are petroleum hydrocarbons which are gaseous at normal temperatures and liquified by pressures of a few atmospheres; they are thus easily stored and transported as liquid in relatively light pressure containers. 'L.P.G.', as they are known, may be derived from wet natural gas containing propane, butane and higher hydrocarbons; refinery distillation, whence propane and butane are obtained from crude oil by pressure distillation; cracking and reforming refinery processes. In a paper by R. F. Horner, P. C. Jarvis and A. G. Turner, at a symposium on the Uses of Liquified Petroleum Gases at the Institute of Fuel during December 1959, are described composition and properties of 'L.P.G.'; historical market development; applications; supply and distribution; future uses in the United Kingdom. Among other advantages is facility of handling and burning; precautionary measures must be taken in design of plant, because of their higher vapour pressure than ordinary liquid fuels. Combustion characteristics of 'L.P.G.' are high calorific value, specific gravity and high volumetric proportion of air required for combustion compared with coal gas; low flame velocity and narrow limits of inflammability compared with coal gas, hydrogen or acetylene. In a complementary paper by J. P. Liotier at this symposium is an account of "Uses of 'L.P.G.' in Industry in France with Particular Reference to the Metallurgical and Ceramics Industries", following developments for commercializing propane in French industrial markets, originally sponsored by L'Utilisation Rationelle des Gax.

Progress in Microchemistry

THE *Microchemical Journal*, 3, 3 (August 1959), contains a collection of review articles on various aspects of microchemistry which might be considered to have a wider appeal than the normal quarterly volume of this journal. The collection, which is generally of a high standard, suffers from a great variation of treatment by the twelve authors who contribute the articles. As an example, the section dealing with "Progress in Elemental Quantitative

Organic Analysis 1958" is very much to the point and gives good coverage to the work in this very important field, while the article dealing with "Progress in Qualitative Inorganic Analysis 1958" is written as a piece of special pleading for the replacement of classical techniques by others recommended by the author without sufficient explanation for his choice. The bibliography covers a wide range and has more references to European work than is sometimes found in American publications. This is probably a reflexion of the world-wide interest in microchemistry. There appears to be no reference in any of the sections to the determination of traces of residual pesticides in animal and plant tissues. This subject, which has a literature as extensive as the whole of the volume under review, would have added to the general value of the collection and could have provided material for discussion of the determination of sub-microgram quantities of organic compounds. The short section on equipment refers exclusively to American instruments. Subjects covered are, microscopy, fractionation and inorganic, organic and biochemical analysis. On the whole this is a useful collection of papers.

Russian Review of Biology

The Institute of Biology, in collaboration with the Department of Scientific and Industrial Research, is to publish an English translation of the *Russian Review of Biology* (Oliver and Boyd, Ltd. £9 for nine numbers in all for 1959 and 1960, and £6 10*s*. per annum for six numbers thereafter). The Russian journal has been running for many years, and contains summaries, each dealing with progress in a specific topic of biological research. The first translated number starts with a polemical discussion of a work by Lenin in relation to Soviet materialist biology. This is followed by review articles on two enzymes (polynucleotide phosphorylase and xanthine oxidase), the use of enzymes in biological investigation, erythrocyte sedimentation and, finally, the immunological reaction in embryos and new-born animals. There are extensive bibliographies, which, incidentally, indicate the familiarity of Russian biologists with research throughout the world. This new translation will help to acquaint more English-speaking workers with the biological research going on in Russia. Under 'current events' there is an appreciative account of a visit by Kh. S. Koshtoyants to some of the biology departments at Cambridge.

Sarawak Museum

The *Sarawak Museum Journal*, Vol. 8, of June 1958 is edited by Mr. Tom Harrisson, Government ethnologist and curator of the Sarawak Museum, and includes some characteristic forthright editorial comments. The volume is divided into five parts—the past, the present, some recent Borneo writing reviewed, Borneo plants and animals, and climate. Although the majority of the articles are of interest chiefly to those who live in Borneo, others, such as a paper on pollen from the South China Sea by Dr. F. R. Van Veen, are of more general application.

Bronze Figures from Nigeria

An illustrated article on some bronze figures from Ita Yemoo, Ife, Nigeria, by Frank Willett, the archæologist of the Department of Antiquities, appeared in the November 1959 issue of *Man*. The finds were unearthed by chance, and luckily Bernard Fagg, the director of antiquities, happened to be in the vicinity. As a result, all particulars of their occurrence, etc., were collected, and the finds themselves carefully preserved. Like the pottery figures discovered some time earlier, they are of great interest, though, perhaps, not so beautiful. An interesting fact is that five of the bronze heads are gagged, and they probably represent victims for sacrifice in view of the sherds of a ritual pot found nearby. Doubtless all these various art discoveries in Nigeria will be published in book form in due course.

Mathematics and Children

An article by Z. P. Dienes, lecturer in mathematics in the University of Leicester, in *Educational Research* shows that there are ways in which mathematical concepts can be caused to develop in children so that the techniques they learn are preceded by an understanding of the corresponding mathematical structures (*Educat. Res.*, 2, No. 1; Nov. 1959). Dienes's scheme has not yet been tried out under actual school conditions, but it is possible to state some qualitative results derived from trials in a number of schools. Schemes of individual mathematical discovery can be worked in large unstreamed classes throughout junior schools; a large majority of normal children can understand the complex workings of the four rules of arithmetic in the decimal and other systems; normal 10-year-old children can learn the use of brackets, the properties of the square, the solution of linear and quadratic equations and the factorizing of quadratic functions, if approached constructively.

It is possible to give children leaving junior school a solid body of practical experiences, impossible to obtain from real-life situations, on which an extensive secondary school curriculum can be based. There are almost limitless possibilities for enlarging the junior school syllabus, by including such topics as theory of groups, usually reserved for university honours courses. There is sufficient evidence to suggest that mathematics can be introduced to a larger section of the child population than had hitherto been thought practicable or possible. This is done by co-ordinating the teacher's work with the natural process of concept formation in the child. It is a challenge to the teaching profession to devise ways in which this much larger body of children can be drawn into the mathematical workshop. By doing so, a large potential of future mathematicians, scientists, and technicians would be created, whose practical bias is likely to make them extremely useful members of an increasingly technological society.

Preventing Evaporation from Reservoirs

Vast quantities of water evaporate from storages located almost everywhere in Australia. Much of the pastoral land lies in regions where evaporation from a free water surface exceeds 6 ft. a year, and annual losses of 8 ft. are not uncommon inland. The Mansfield process, devised by Mr. W. W. Mansfield of the Division of Physical Chemistry of the Commonwealth Scientific and Industrial Research Organization (Australia), has provided pastoralists and farmers with a simple method of cutting these enormous losses by at least a quarter. The process involves spreading a very thin film of hexadeconal (a pure form of cetyl alcohol) over the surface of stock tanks and small farm dams. The film is continuously replenished as required from beads of hexadeconal housed in a small raft with gauze windows. Because of its enormous potential significance, details of the Mansfield process were released at an early stage in its development. This has allowed more experience to be accumulated under different conditions throughout Australia, and widespread use on thousands of dams has confirmed its potential value. However, further use has emphasized that good results are not obtained unless the raft used meets the Commonwealth Scientific and Industrial Research Organization requirements. The condition of the raft must be checked periodically. A recent article discusses some of these practical points, and describes how the few unforeseen difficulties that have cropped up can be overcome (*Rural Research in C.S.I.R.O.*, No. 28 ; June 1959).

Research in the Hat and Feltmaking Industries

The twelfth annual report of the Director of Research, British Hat and Allied Feltmakers Research Association, covering the year ended August 1959, stresses the addition to the research programme of a study of the shock-absorbing properties of felt and other materials, relative to protective headgear (Pp. 20. Droylsden, Manchester : British Hat and Allied Feltmakers Research Association, 1959). Other work, which has largely been in continuation of work already projected, has included further study of the carrotting of fur, an examination of the fibre properties of rabbit fur from different sources and attempts to assess the feltability of vials by simple tests that could be carried out in the factory. A theoretical study of the free oscillation of the beam system of the felt-hardening machine suggested that the pattern of behaviour when the weight is adjusted reflects the changes in the amplitude and natural frequency of vibration of the beam assembly. The experimental programme with selected polyethanoxy assistants in dyeing felt showed that the assistants were selective in action with acid-levelling, acid-milling and both 1 : 1 and 1 : 2 premetallized colours and even in a particular class. In studies of the relation between the size and shape of the hat body required to make hats of a given size, brim-width and crown-shape, wide differences were observed in the stretch pattern, and theoretical analysis indicated that the size and shape of hat bodies to give hats with a predetermined stretch pattern could be calculated if the geometry of the stretching could be stabilized. A review of the system of TDM indexes for measuring felt quality showed that the dependence of physical properties upon form weight changed with time and that periodic revision of the indexes was required to avoid obsolescence. A revised system has been proposed, while further work on frictional properties has provided an explanation of faults in felt which developed when bodies were pounced wet. Lists of publications, officers and staff are included.

"A Microsomal Malic Dehydrogenase"

Dr. Kenneth H. Shull writes : "It has come to my attention that three errors were made in my communication under this title in *Nature*, 183, 259–260, January 24, 1959. In both Figs. 1 and 2 the sentence in the legends referring to the abscissæ should read 'The abscissa is the reciprocal of the substrate (oxalacetate) concentration in $\mu M \times 1{,}000/3$'. The value of the Michaelis constant, *Km*, line 24, column 2, p. 259, should read $4 \cdot 66 \times 10^{-5}$ *M*. The oxalacetate concentration, line 9, p. 260, should read 253 μM. These errors arose from the fact that I plotted units of mass, micromoles of oxalacetate per cuvette, rather than units of concentration. Since each cuvette contained a total volume of 3·0 ml., these reciprocal values for concentration are too large by a value of 1,000/3. The Michaelis constant which was determined graphically from Fig. 1 is thus too small by this same factor".

Announcements

Sir Gavin de Beer will retire from the directorship of the British Museum (Natural History) on April 30. He will be succeeded by Dr. T. C. S. Morrison-Scott, at present director of the Science Museum, and previously on the staff of the British Museum (Natural History) in charge of the Mammal Room.

No. 11, Vol. 5 (November 1959) of "The Bibliography of Scientific Publications of South and South East Asia", compiled jointly by Unesco Science Co-operation Offices for the area and published by Modoc, National Physical Laboratory, New Delhi, contains a further 608 classified entries.

The second Asian/Pacific Congress of Cardiology will be held in Melbourne during the last week in May. Further information can be obtained from Dr. A. E. Doyle, Alfred Hospital, Melbourne, S.1, Victoria, Australia.

La Société de Chimie Physique is arranging a meeting on the Structure of Graphite and the Kinetics of its Reactions during May 31–June 3. Further information can be obtained from the Secrétaire Général de la Société de Chimie Physique, 10 Rue Vauquelin, Paris-V^{e}.

The series of Summer Schools in Theoretical Chemistry which are held annually at Oxford is being continued this year during September 10–24, under the direction of Prof. C. A. Coulson. Further particulars can be obtained from the Assistant Secretary, Delegacy for Extra Mural Studies, Rewley House, Wellington Square, Oxford. Applications should be made before April 30.

A symposium on Molecular Structure and Spectroscopy will be held at the Department of Physics and Astronomy, Ohio State University, during June 13–17. There will be discussions of the interpretation of molecular spectroscopic data as well as methods for obtaining such data. In addition, there will be sessions devoted to those phases of spectroscopy of current interest. Further information can be obtained from Prof. R. A. Oetjen, Department of Physics and Astronomy, Ohio State University, Columbus 10, Ohio.

A two-day conference, to be held in Philadelphia during April 28–29, on "The Role of Nuclear Propulsion in our Future Merchant Marine", has been arranged by the Atomic Industrial Forum, an association of the atomic industry in the United States, in co-operation with the U.S. Atomic Energy Commission and the Maritime Administration. The provisional agenda includes : economics of nuclear ships, safety and liability problems, progress in foreign nations, and future prospects for the U.S. programme. Further information can be obtained from the Conference Manager, Atomic Industrial Forum, 3 East 54th Street, New York 22.

SCIENCE IN CIVIL LIFE IN BRITAIN

TWO recent debates in Parliament are of special interest for the further light thrown on the Government's intentions with regard to the Minister for Science. The first of these, in the House of Commons on December 7, was the outcome of a supplementary estimate not exceeding £4,080 for the Office of the Minister for Science for 1959–60, moved by Sir Edward Boyle, Financial Secretary to the Treasury. Sir Edward explained that this addition to the original Vote of £36,090 covered the remaining cost for the staff of the Atomic Energy Office and the Lord President's Office, and in particular the new provision for a chief information officer and supporting staff and provision of additional staff for the former Lord President's Office. He pointed out that Lord Hailsham's responsibility for the Atomic Energy Authority is in a sense a reversion to an earlier practice; but his responsibility for the four great executive research councils involves a considerable volume of Government expenditure; for the Department of Scientific and Industrial Research, the current expenditure, he said, is £13·25 million; for the Medical Research Council £3·5 million and for the Agricultural Research Council, just under £6 million. The Atomic Energy Authority accounts for £55 million current and £37 million of capital expenditure. The Minister for Science is also responsible for the Advisory Council on Scientific Policy and its Scientific Man-power Committee, the Overseas Research Council, and the Steering Group for Space Research; and Sir Edward Boyle emphasized the close relation of the Advisory Council for Scientific Policy both with the National Research Development Corporation and with defence science, and said that Lord Hailsham has already asked the Council to advise him on the balance of our national scientific effort. Within the four main research councils there are 97 research stations and establishments, and Lord Hailsham attaches great importance to links between these establishments and the universities and technical colleges, and will surely make these links and relations as fruitful as possible.

So far as defence research is concerned, the care of such activities, especially in the field of aircraft, guided weapons and electronics, are to be transferred from the former Minister of Supply to the new Minister of Aviation; but the responsibilities of the Minister for Science for space research will ensure very close contact with this work. Sir Edward also anticipated that the Minister would use the establishments of the research councils to reinforce the work of numerous Ministries and give them general guidance and advice in matters of scientific policy; but he suggested that the greatest challenge of all is to ensure that modern ideas and discoveries in science and technology are effectively and rapidly applied in British industry, and in this he thought development contracts may prove of service.

In the debate, some doubts were expressed as to the adequacy of the scientific staff in the Minister's office, and Mr. A. Greenwood, while welcoming the tribute paid to the Advisory Council on Scientific Policy, referred to the failure to implement the Council's recommendation regarding a national scientific reference library and suggested that the Council might need a stronger secretariat and an intelligence unit of its own. He and almost every speaker in the debate was critical of the absence of a spokesman for the Minister in the House of Commons. Sir Arthur V. Harvey referred to the need for greater co-ordination, mentioning especially the Faery rotodyne and Jodrell Bank Experimental Station. Mr. A. Albu stressed the need for much more money for basic research and for carefully selecting the lines of development on which our resources should be concentrated. Mr. Robert Carr suggested that the Minister might look into the possibility of stimulating research in industry through research contracts, and was concerned as to the possibility of too great a split between defence science and civil science under Government control. He also stressed the need for an adequate supply of technicians and skilled workers, and hoped that before long one Minister, instead of the present six, would answer in the House of Commons for the Minister for Science. Both Mr. Facey-Jones and Mr. Chuter Ede referred to the importance of full publication, Mr. Ede pointing out that secrecy is the great enemy to the progress of science, and Mr. D. Price stressed the value of an understanding of science in the Civil Service.

The Minister of Education, Sir David Eccles, replying on the debate, was able to show good reason why he should reply for the Minister for Science, particularly in view of his responsibilities for the schools and technical colleges. He believes there is a good prospect of reaching our target of 20,000 scientists and technologists. Although we are still short of science teachers, the numbers in grammar and technical schools are improving, and in 1959–60, 865 graduates in science entered university departments of education compared with 639 two years ago. He thinks that the Minister for Science will collect and co-ordinate relevant views on the controversial issues of scientific man-power, and place his conclusions before the education departments, universities, other scientific bodies and industry, and that he would be in a better position than any other Minister or agency to form estimates of the scientific resources and needs of Great Britain. The appointment of a Minister for Science has inevitably created some awkward administrative problems, but with good will there is no reason why they should not be settled.

The second debate, on science in civil life, opened by Lord Taylor in the House of Lords on December 9, is of greater interest because it provoked a further account from Lord Hailsham himself of his conception of his post as Minister for Science. Lord Taylor, after pointing out that it was no new thing for a senior Minister to be in charge of the main civil scientific Departments, referred more particularly to medical science and expressed the opinion that the Medical Research Council is a model of Government intervention in the sciences. Nevertheless, he thought that too much paper work comes to the Council for final decisions, and that the Council sometimes fails to try out new ideas outside the conventional rut of thinking; he also suggested that besides, as a broad principle, backing good men, it might more often suggest the problems to be tackled. In this connexion, Lord Taylor named three specific projects and then referred to a third difficulty arising in relation to the universities, through the shortage of endowed readerships and research professorships, and the consequent loss of good research workers in the medical field to clinical medicine. Universities, he said, are also unwilling to recognize Government research units and organizations as approved places for study for higher degrees, and he mentioned specifically research hospitals or hospitals with a specialized research unit. Like several subsequent speakers, he urged the need for a great effort in the social sciences, and suggested the establishment of a research council for the social sciences.

Lord Hailsham welcomed Lord Taylor's suggestions as illustrating the immense range of opportunity, and, replying to a specific question about scientific attachés, said that a fifth scientific attaché would be appointed, this time in Moscow. Dealing with the question in its broadest aspects, he said that the relation between Government and science and technology in all its aspects is one of the great challenges to the present Parliament. He himself is anxious to be as accessible as possible to members of both Houses, and insisted that the creation of his post was an evolutionary rather than a revolutionary step, and that no one should be dogmatic about the direction in which this kind of organization would lead us. Of his Ministry, he observed that there are only 39 people concerned with the expenditure of some £112 million of public money, and the executive work is carried out by scientists with a relative freedom, though subject to Government direction of one kind or another.

Looking further at the nature of the challenge to which he referred, Lord Hailsham said that science is not something which can be disentangled and treated separately from life. The approach of a scientific society and the need to learn how to operate this society and understand what it means involves talking in terms of generations rather than parliaments. What we do and say about a scientific society must be set against the present background: perhaps twenty or thirty years of intensive education, training and effort have been required to produce the men upon whom ultimately this kind of progress in human knowledge will depend. Lord Hailsham pointed out that this small group of pioneers needs the support of much more scientific literacy in the governing elements of the country and accordingly of our whole society, and he stressed the importance of the educational system developing such literacy. Science also has to be sustained by an immense army of skilled craftsmen and technicians, and while the Government must be responsible for the whole and for finding and strengthening the weak places, this must also be the joint responsibility of all concerned with the administration of any part of our society. Above all, scientific work must and can only be administered by scientists. Lord Hailsham also said that the distinction between the various defence and civil sciences is wholly artificial and arbitrary, and that scientists would see in a Minister for Science a real assurance that the civilian applications of science would not be overlooked because of the greater expenditure on defence projects. Science and scientists are not solely concerned with national things, and the values of the scientist are not purely material. Replying to Lord Morrison, Lord Hailsham firmly vindicated the creation of his office as Minister for Science; but he thought the proposal for a social science research council might be premature. He agreed with Lord Adrian as to the importance of an adequate supply of technicians in order to ensure efficient use of the services of scientists and technologists, though this presents some difficulty at the universities, and he also agreed as to the importance of sciences that do not fall into the normal classification. The Advisory Council on Scientific Policy has already been asked, in looking at the general balance of the scientific effort in Britain, to pay special attention to oceanography, seismology and astronomy and the relative stress to be placed on biology. He also firmly maintained the soundness of the decision to limit our effort in space research and emphasized the importance of international co-operation in this field. He agreed with Lord James of Rusholme as to the importance of science teaching, and that although accommodation is less important than the provision of teachers, it could become a limiting factor and therefore requires attention. Lord Hailsham hoped that during the coming session in Parliament there will be some debate on the size of universities and their contribution to our scientific effort, and that the present debate would be only the first of many on science in civil life.

SCIENCE AND FOREIGN POLICY IN THE UNITED STATES

IN the years since the Second World War, non-military scientific developments have played important parts on the international stage. With technology accelerating at an amazing rate, what effects will it have on foreign relations problems in the future? Can we look ahead and try to ascertain what science will produce, and then take advantage of the product in foreign policy planning? These were questions posed by the Committee on Foreign Relations of the United States Senate (*Research for Industry*, 11, No. 6, Nov.–Dec., 1959). Stanford Research Institute scientists in all divisions provided assistance to Eugene Staley and Guy Benveniste in attempting to find some of the answers. The team indicated in its report that, while some future scientific developments may help solve foreign policy problems, the net effect of technological progress in the next decade is likely to be to create or intensify such problems. Thus, the security and well-being of the United States calls for a re-appraisal of present effort with the view of directing more energy toward non-military foreign policy challenges. Foreign policy planning should include continual review of scientific advances and their significance for international relations.

A specific suggestion was to establish a research and development office in the Federal Government oriented to identifying problems in newly developing countries and then stimulating research on these problems. In addition, an international development year might be organized along the lines of the International Geophysical Year with the aim of assisting newly developing nations on a grand, concerted scale. In order to utilize science and scientists to facilitate understanding between nations, a United Nations weather and climate agency might be established to carry on research and ultimately to have authority over all weather and climate control undertakings. A United Nations university or system of universities could be dedicated to the advancement of science and the humanities. Other suggestions envisaged are the creation of an international translation and scientific information centre, and the establishment of adequate facilities to conduct research on technical problems of disarmament.

This study is the second of fifteen the Senate Relations Committee has authorized to examine United States foreign policy. It is designed to provide the Committee with background information, and the members are free to accept or reject the findings. The chairman, J. W. Fulbright, has announced that public hearings will be held later "to receive testimony from all interested parties in order to test the soundness of the findings and recommendations in all the studies undertaken".

NUTRITION IN EUROPE

A SYMPOSIUM on "Education and Training in Nutrition in Europe", arranged by the Food and Agriculture Organization of the United Nations and the World Health Organization through its European Regional Office, was held in Bad Homburg, West Germany, during December 2–11, 1959. There were some sixty participants from twenty-two European countries, with Israel and Tunisia also represented. They belonged to a number of professional groups and included nutritionists, dietitians, physicians and public health officials, educationists, home economists and agronomists. The symposium was, in fact, designed to secure an inter-disciplinary approach.

The Food and Agriculture Organization and the World Health Organization are both concerned with nutrition ; the former because its basic objective is to satisfy nutritional needs by making the necessary foods available, the latter because of the relation of nutrition to health. For many years they have collaborated in programmes and projects in this field, under the guidance of a joint expert committee. The meeting in Bad Homburg was one of a long series of joint undertakings.

The symposium began by attempting to define the nature and extent of problems of nutrition in Europe, a task facilitated by reports prepared beforehand by the participating countries. Generalization was naturally found to be difficult, in view of the wide differences in the countries represented. For northern, western and central Europe the picture is, on the whole, a favourable one. Under-nutrition and severe malnutrition are rare nowadays, the temporary food shortages of the War have been replaced by abundance, perhaps even by over-abundance. The child of to-day is more wisely fed than his predecessor of thirty or forty years ago and a number of food-deficiency states and diseases once prevalent have been largely eliminated ; it was noted, for example, that in certain countries teachers of medicine have great trouble in finding cases of rickets to demonstrate to medical students. However, even in the best-fed countries the goal of food for health has not been fully attained. For example, dental decay was mentioned as a widespread and distressing condition due to dietary errors, though unfortunately there is not yet general agreement on what these errors are. Again, over-nutrition and obesity are in a sense a form of malnutrition, and there was agreement both on their increasing prevalence and danger to health. The still unresolved problem of the relation between fat intake and the modern scourge of coronary disease was regarded as being somewhat outside the terms of reference of the symposium, but its importance was stressed by many members. It was pointed out that the increasing proportion of elderly people in the population presents dietary problems to which insufficient attention has as yet been given.

In other parts of Europe malnutrition still occurs in various groups of the population and in certain areas within the countries. The groups most affected are infants, young children and expectant and nursing mothers. It was reported that rickets is common in Poland and that pellagra is still found in a few pockets in eastern Europe.

More information on existing food consumption and state of nutrition is required, to help Governments in establishing national food policies which take account of nutritional needs, and to guide efforts to improve diet through education. With regard to the latter, however, mere average data on the quantities of various foods which people eat, and their calorie and nutrient value, are not enough. It is also necessary to understand *why* they eat what they do in the way they do. Food patterns are influenced by tradition and by a host of economic, social and psychological factors of which the 'educator' must be aware. The symposium entertained itself from time to time by exchanging anecdotes on the extraordinary ideas which people often have about food and diet.

After analysis of the situation had indicated that there is plenty of room for improvement and a wide need for public enlightenment, the symposium considered the adequacy or otherwise of the training in nutrition now given to various professional groups, dealing *seriatim* with nutritionists, dietitians, medical students, public health personnel, home economists, school teachers and agronomists and agricultural extension workers. The nature and content of training were discussed under each heading, after an introductory paper presented by a chosen member. Professional nutritionists (of whom there are all too few) need knowledge which is deep enough to enable them to provide leadership and guidance in their countries. Dietitians, defined as a class of worker concerned with organizing the feeding of groups and individuals, in particular the sick, also need extensive specialized training. With respect to most of the other groups, the symposium, aware of the need to avoid the further over-loading of curricula, did not favour adding nutrition to the curriculum as a separate subject ; it expressed preference for teaching it as part of other related subjects, provided the knowledge so imparted is inter-linked and becomes an 'integrated' whole. On the training in nutrition now given to medical students, the views of those present at the symposium were unfavourable; it was noted that while students receive some instruction in the science of nutrition in its clinical aspects, this is not given in an 'integrated' way and is rarely related to the everyday problems of family life.

Emphasis was placed on the contribution to popular education which can be made by the public health nurse through her contacts with families in their homes. Home economists, a growing professional group in a number of European countries, can also influence families directly. As part of her work to improve family living conditions, the home economist is concerned with the planning of the family budget, the preparation of family meals, the domestic production, storage and preservation of food.

The training in nutrition of school teachers, so that they can teach its elements to their pupils, at an impressionable age, was discussed at some length. Ways of including nutrition in the teaching of subjects such as biology, health education and home economics were outlined, and it was agreed that it should not form a special and separate addition to school curricula. The need for simple and practical instruction was stressed, and attention was directed to the educational value of school meals.

Since good nutrition depends on the supply of enough of the right sort of food, it was appropriate for the symposium to consider the training in nutrition of agronomists and agricultural extension workers and their role in national nutrition programmes. Students in agricultural colleges learn much about the feeding of animals, but practically nothing about the feeding of human beings, which is after all the *raison d'être* of their profession.

Finally, the educational specialists present insisted that their colleagues should glance at modern educational techniques and modern ideas about the learning process, pointing out how these can be applied in the nutritional field. They were heard respectfully by a group in general more familiar with old-fashioned methods of instruction.

The symposium was aware that some of its conclusions cannot be exactly applied to the different countries represented, but require adaptation to the circumstances and needs of each. In the animated discussions, however, a large measure of agreement was reached on major points. Throughout, the friendly atmosphere characteristic of international technical meetings prevailed. W. R. AYKROYD

ELECTRON–PHONON INTERACTIONS

A CONFERENCE on Electron–Phonon Interactions in Solids was held at the Clarendon Laboratory, Oxford, during December 17–18. The Conference was held under auspices of the Physical Society and the delegates were welcomed by Dr. K. A. G. Mendelssohn (Oxford) on behalf of the President of the Society. The subject-matter of the Conference was of a very specialized nature and the organizers had further restricted the field of discussion by excluding topics directly related to superconductivity. It was therefore most encouraging that more than one hundred delegates attended the Conference. Among these were visitors from the United States, Belgium, Canada, Holland, South Africa and Switzerland. These delegates were not all specialists in the subject-matter of the conference, but nevertheless the discussions which followed the formal papers were often lively and to the point.

The Conference devoted its attention to those aspects of electron–phonon interactions which are most closely concerned with the complicated processes usually classified as 'transport phenomena' in metals and semiconductors. Examples of such phenomena are the electrical and thermal conductivities or the thermo-electric effects. The classical kinetic theory of the 'free electron gas' gives a very simple and elegant explanation of most of these effects in a first approximation. However, this theory makes the very fundamental assumption that the electron gas is in thermal equilibrium at some particular temperature, but does not clearly describe a mechanism by which this equilibrium can be achieved. The approach to equilibrium is discussed in terms of 'collisions' which do not involve interactions. The difficulties of a more rigorous theoretical treatment were emphasized by Dr. G. V. Chester (Birmingham) and Dr. J. M. Ziman (Cambridge). Dr. Chester, in attempting a more rigorous approach using the 'adiabatic' approximation, was rather surprised when experimentalists in his audience pressed him for some numerical orders of magnitude. Dr. Ziman reviewed the different methods at present used for estimating the electron–phonon interaction. He suggested that the strength of this interaction in metals was related to the Fermi energy; but the discussion which followed Dr. Ziman's paper showed that some delegates thought that he may have over-simplified the problem by laying such stress upon one parameter—the closeness of approach of the Fermi-surface to the Brillouin-zone boundary.

Prof. F. J. Blatt (Michigan State University), Dr. D. K. C. Macdonald (National Research Council, Ottawa), and Dr. J. R. Drabble (General Electric Co.) presented papers dealing with experimental investigations of thermo-electric effects in metals and semiconductors. Prof. Blatt described an interesting series of experiments which had been carried out using alloys of zinc, germanium, cadmium, indium, tin and antimony with copper. Of these alloys, 1 per cent zinc or germanium alloyed with copper gave a change in the thermo-electric power consistent with the expected phonon drag contribution estimated from pure copper. On the other hand, the addition of 1 per cent cadmium, indium, tin or antimony to copper reduced the phonon drag contribution almost to zero by virtue of phonon scattering arising from the solvent mass difference.

On the morning of the next day, Dr. A. B. Pippard (Cambridge) gave a simplified theoretical treatment of the anomalous absorption of ultrasonic waves by conduction electrons when the metal is situated in a magnetic field. Ultrasonic waves are essentially very long wave-length phonons, so that this technique provides in principle a direct approach to electron–phonon interaction processes. Unfortunately, this anomalous absorption is difficult to measure and is often masked by other attenuating mechanisms such as may arise from the movement of dislocations. The effect sought for has apparently only been observed in copper and possibly in lead. Other papers during the morning were contributed by Dr. R. Furth (London) and Dr. L. Mackinnon (Leeds).

The session during the afternoon was opened by Dr. S. Raimes (London), who gave a careful account of the description of transport phenomena in metals using the techniques of plasma theory. This was followed by a paper in which Dr. R. J. Elliott (Oxford) directed attention to an alternative line of investigation which might provide useful information about electron–phonon interactions. He suggested that further electron-spin resonance experiments should be undertaken with metals in order to measure the electron spin-lattice relaxation time in more detail. The final paper was given by Dr. D. M. S. Bagguley (Oxford). He described some experiments using cyclotron resonance techniques to investigate the different collision processes for carriers in germanium.

All the delegates who attended the conference were grateful to the organizers for their efforts in providing an opportunity for listening to the formal papers and for informal discussions between colleagues. Such informal discussions are themselves a sufficient and complete justification for a conference of this nature.

D. M. S. Bagguley

BRITISH GELATINE AND GLUE RESEARCH ASSOCIATION

THE eighteenth meeting of the Research Panel of the British Gelatine and Glue Research Association was held on November 12 with Mr. J. N. Blake (Richard Hodgson and Sons, Ltd.) in the chair. Mr. Blake introduced Dr. D. A. Sutton, who had recently succeeded Mr. A. G. Ward as director of research.

Dr. J. E. Eastoe (Department of Dental Science, Royal College of Surgeons of England) presented the first paper entitled "Bone—The Structure of a Biological Microcosm". After considering bone as one of the several mineralized biological tissues, note was taken of its occurrence in the vertebrate subphylum of the chordate phylum. Dr. Eastoe discussed bone at descending orders of size beginning with the skeleton, its function and the integration of its component parts, and continuing through the cellular level to electron microscope studies of bone mineral and collagen and thence on to the organization at the molecular level of these two main components. He concluded with a discussion of the hypotheses advanced to explain mineralization. Particular reference was made to the work of Glimcher, Hodge and Schmitt showing that mineralization is induced from metastable solutions containing calcium and phosphate only when the collagen fibrils present have the 640-Å. spacing, and that deposition can be prevented by traces of polysaccharide components. Chemical differences exist between bone and skin in that the former contains less polysaccharide and that its lysine and hydroxylysine have ε-amino groups more reactive towards fluorodinitrobenzene according to recent work by Solomons and Irving.

In the second paper, "Shrinkage of Cherries in Jelly", Miss M. J. Anthistle (Fruit and Vegetable Canning and Quick Freezing Research Association) demonstrated that the shrinkage which has been noted on storage can be virtually eliminated by adjustment of the surrounding gelatine gel (isoelectric *p*H, 4·7) to about *p*H 4·0; below this *p*H shrinkage occurred and above it a slight degree of swelling. The effect was not dependent on the sugar concentration. Miss Anthistle then considered the phenomenon in terms of the Donnan membrane equilibrium theory and deduced that shrinkage should be minimal at the isoelectric *p*H of the gelatine; in fact, it was minimal between *p*H 4·0 and 4·5. The *p*H of minimum shrinkage is thus somewhat lower than the isoelectric *p*H of the gel. In the discussion, it was suggested that the slight discrepancy might be due to an effect upon the equilibrium caused by the protein and pectin inside the fruit.

A short paper was then given by Mr. A. M. Kragh (British Gelatine and Glue Research Association) entitled "The Equilibrium Moisture Content of Plasticized Gelatine Gels". Glycerine and a sugar mixture (4 sucrose : 1 glucose) were used as plasticizers and relative humidities of between 35 and 93 per cent were studied. Temperature had a negligible effect upon the equilibrium moisture contents. Unless the relative humidity was very high, the equilibrium moisture content of the mixtures did not vary greatly over a wide range (0·5 : 1–4·0 : 1·0) of plasticizer : gelatine ratios.

D. A. Sutton

INTERLINGUA

THE free circulation of ideas and information is not less important for science than the circulation of the blood is for the body. This circulation is impeded by the publication of the results of scientific research in a multiplicity of languages. At least 50 per cent of the scientific literature of the world is published in languages that more than 50 per cent of the scientists of the world are unable to read. The number of published articles is growing rapidly; chemical literature, for example, has doubled itself in the past eight and a half years. There is also an increasing number of international meetings. There is thus not only the difficulty of reading published articles but also that of participating in discussions with research workers from other countries.

According to Forrest F. Cleveland, the scientist has two requirements. First, he has to scan the current literature to obtain ideas and information with respect to new developments in his field. Secondly, he must read in detail those articles that pertain to his own investigations. These requirements are largely frustrated by the language barrier (*American Scientist*, 47, No. 3, 1959). Scientific work would be facilitated if the results of scientific research were published in a single language that every scientist would be able to read at sight. Such a tool of intercommunication became available with the publication in 1951 of the "Interlingua–English Dictionary" and the "Interlingua Grammar" (Storm Publishers, 80 East Eleventh Street, New York 3). This was the culmination of twenty-seven years of research by the International Auxiliary Language Association in New York. Interlingua was developed by taking the words of vocabularies of the European languages (including English), standardizing or rationalizing them to remove regional irregularities and peculiarities, and constructing a simple grammar for use with the resultant vocabulary. An international language was obtained, which in a large measure is already in use and which can be read practically at sight by every educated person. The basic criterion for the acceptance of a word for the Interlingua vocabulary is that it must be present in corresponding forms and with corresponding meanings in at least three of the four language units: (1) Italian, (2) Spanish, and/or Portuguese, (3) French, and (4) English—with German and Russian as possible substitutes.

Impressed by the easy readability of Interlingua, Cleveland began, in May 1952, the publication in this language of a small periodical, *Spectroscopia Molecular*. It contains brief reports of new research results, summaries of important articles in the current literature, reports of spectroscopic meetings, reviews of new books, a calendar of future spectroscopic events, details about new instruments, and news about spectroscopists and recent developments. The experience of this small periodical provides a proof of the utility of Interlingua for intercommunication in the world of science.

Perhaps the greatest use of Interlingua to date has been in medicine. More than twenty medical journals publish extracts in Interlingua with all their original articles. In addition, Interlingua has been used for summaries in the programme of seven international medical congresses. *Science News Letter* publishes each month a summary in Interlingua of recent scientific developments.

To assist editors and authors who wish to study the possibility of increasing the extension of their work by the use of Interlingua, Science Service, Inc., has established an Interlingua Division. This is located at 80 East Eleventh Street, New York 3, and is under the direction of Dr. Alexander Gode.

RESEARCH AND DEVELOPMENT

CAN the effectiveness of research and development be measured ? More precisely—given a certain amount of research effort, in a given field, can the rate at which useful results will emerge be predicted ? These are some of the questions asked during a recent intensive study, "Basic Research in the Navy," carried out for the Naval Research Advisory Committee by Arthur D. Little, Inc. (Industrial Bulletin of Arthur D. Little, Inc., 369, Nov. 1959). In its report to the Secretary of the Navy, the Committee recommended further "research on research"; one approach is through a mathematical model describing the mechanisms of discovery and application.

The model describes a two-stage process; in the first stage, knowledge is discovered, and brought from the realm of the unknown into the known. In the second stage. combinations of the known facts are fitted together and applied. Formulation of the inventive process in this way emphasizes one important point: for every invention there is a key fact, or relation, or principle—the last to be discovered of all those necessary before the invention could be made. From this it follows that the date of discovery of this key fact is the earliest date upon which the invention could be made at all—although, of course, many inventions are not made until long after the discovery of the key fact.

There is a body of available knowledge, containing a certain number of key facts, corresponding to an equal number of possible inventions. If no new knowledge is added by research, these represent all the inventions which can be made. But the more research effort is applied, the more new facts come to light. It is also proportional to the size of the pool of (undiscovered) knowledge. The consequences of this ratio are interesting; the equation describing the rate of depletion of basic knowledge—the unknown subject—is an exponential decay curve like that used to describe the rate of decay of a radioactive substance. This is the model for the first stage of the research process.

The second stage concerns the application of discovered facts through invention. Here again the rate of progress is proportional to the amount of effort expended and to the size of the pool of knowledge—in this case, the number of discovered, but unapplied, facts. Yet a fact may be applied many times, in different combinations with other facts. It is not the unit of knowledge that is important—rather, it is the conclusions drawn from a number of units. To determine a rate for the second stage properly, one must invoke the techniques of modern algebra.

There is, also, the question of the time-lag between discovery and application; for the second stage, as well as the first, one can draw an analogy with the process of radioactive decay. The body of known but unapplied facts is considered, on this model, to have a well-defined half-life, but the expected time for any one fact to be applied may range from very short to extremely long. The expected half-life itself is a variable quantity which depends on the amount of effort expended on development work.

By putting these various factors together, for the second stage an S-shaped curve is obtained indicating first a slow rate of application, then a more rapid increase, and finally a plateau; curves of this type are familiar to economists for describing the development of a market or a new product. This is the model for the inventive process, and it is confirmed by observation.

Perhaps the most interesting feature of the model is that an optimum ratio for the effort to be applied to the two stages of discovery and application of knowledge can be derived. That is, one can in theory answer the question: For maximum productivity of a research programme, what percentage of the budget should be devoted to basic research, and what part to applied research ? The model suggests that to develop one large and complex field, basic research should not fall below about 20 per cent of the total research budget.

UNITED KINGDOM HOSPITAL LIBRARY SERVICES

A PILOT survey of hospital library services has been made by an independent committee, of which Mr. J. A. M. Ellison-Macartney was chairman, sponsored by the King Edward's Hospital Fund for London (Hospital Library Services: a Pilot Survey. Report of an Independent Committee sponsored by King Edward's Hospital Fund for London. Pp. 56. London: King Edward's Hospital Fund for London, 1959. 2*s.* 6*d.*). Its report, now published, directs attention to the apathy of some hospital authorities and officials and to the inadequacy of much accommodation, but the greatest weakness uncovered by the survey was the quality of the books provided by the smaller voluntary organizations. The Committee believes that ideally the public libraries should be the major source of supply of books and that this should become a recognized function and duty of all such libraries. Nevertheless, the survey also revealed the great strength which lies in the supply of voluntary librarians, and the Committee also believes that ideally the staffing of hospital libraries could be undertaken by voluntary organizations in conjunction with the local public libraries supplying the majority of the books.

In general, hospital library services require a new look, and the Committee recommends that hospital authorities at the highest level should regard it as an essential duty to see that an efficient service is provided in all hospitals (except where special circumstances render it undesirable) rather than leave the decision to be taken at a lower administrative level. Far greater positive interest in the library service should be taken at all levels of hospital authorities and staffs; it should no longer be left in the main to voluntary helpers with the minimum of support in interest, funds and equipment. All architects' plans for new hospitals or extensions to existing hospitals should in future include library accommodation conveniently sited, and certain standards for accommodation and equipment are recommended for consideration. In particular, it is emphasized that because most library services are likely to continue to be run by volunteers, particularly women of middle age, the siting of library accommodation, height of shelves, weight of trolleys, heating, lighting and ventilation are of paramount importance. The standard of books provided should be that of books provided to the general public by the best public libraries, and the Committee recommends that for a hospital of average size, annual expenditure on new books should be not less than 6*s.* per bed. All hospital library services should include the provision of books to hospital staffs, and the Committee suggests that valuable training courses run by St. John–Red Cross should be open to all hospital librarians. The question whether books are capable of carrying tuberculosis infection requires scientific investigation and an authoritative pronouncement. The Committee believes that with the existing variety of library services, full efficiency cannot be attained on a basis of less than £1 per bed per annum at present prices, or £3 per bed per annum if salaries, but not overheads, are included.

THE ATLANTIC EEL PROBLEM

RECENTLY Tucker[1] published his view on the origin of the European eels. He advocates the revolutionary theory that all the European eels are the offspring of American parent stock. His argument is presented under three headings, of which the first, dealing with the return of the silver eels towards their breeding places, is in my opinion the most important one. Therefore, special attention will be paid to this section of Tucker's article.

Tucker begins by laying stress on the fact that the European silver eel is already well advanced towards being a reproductive oceanic fish despite the long journey which supposedly lies before it, this in marked contrast with the American silver eel, which is relatively retarded. The conclusion is drawn that this is just the reverse of what one would anticipate, taking into consideration the distance it has to go.

The impossibility of providing exact information on the time required to become a reproductive fish renders this subject elusive of criticism and debate. Comparison with other species of fish is moreover of little value; one should in my opinion concentrate on the features and habits of the European silver eel itself.

For the same reason the next paragraph dealing with the comparison of external features of both species under consideration cannot lead to an irrefutable conclusion. The only reasonable conclusion one could draw from the differences mentioned is, in my opinion, that there is every reason for believing in the existence of two really distinct species, which is just the opposite of what Tucker tries to demonstrate.

According to Tucker, the longevity of silver eels in captivity is irrelevant. We know, however, that the silver eels, kept in the tanks of the eel merchants, are always on the move; when the water in the tanks is in motion, the silver eels are swimming in the upstream direction. Despite the rather unfavourable conditions in the tanks, the silver eels go on swimming for months and months in succession. It is certainly a remarkable fact that such eels are, even after a period of prolonged storage, fat enough to be attractive for the consumer, for they can easily be sold at a fair price. This demonstrates that silver eels are able to move over huge distances without degeneration of their tissues. It seems therefore that this matter cannot be considered as irrelevant to the subject under discussion.

Two other items in Tucker's article are open to doubt:

(1) If one assumes with Tucker that the migrating eels must use a very simple orientation mechanism

based on currents, temperatures, and/or salinity conditions, and next, considering the complexity of the actual situation, concludes that such a system would fail to guide the eels to their supposed spawning grounds, this reasoning cannot be used as evidence to demonstrate that the eels will not reach such spawning grounds at all. Such a reasoning would indeed be comparable to the following: We assume that migrating birds orientate themselves on wind-direction and wind-strength. Since such a system cannot possibly guide the birds towards their destination, we find ourselves forced to conclude that birds do not reach their destination at all. Since we all know that the birds do reach their destination the only reasonable conclusion is that our assumption was not sound. Unfortunately we do not yet know how eels do manage to orientate themselves; but this also applies to birds: we do know for sure that they are capable of a perfect orientation but fail to understand just how.

(2) Tucker supposes that all European silver eels use the same pattern of behaviour and concludes that they therefore cannot all of them reach their destination. This conclusion is used to support his theory that European eels do not reach the Atlantic spawning grounds at all. Tucker, however, designs a migration system for the American silver eels; he finds himself forced to conclude that the Mississippi eels do not fit in this system. Tucker states then: "the fate of these need not concern us". If so, why does the fate of the Black Sea eels or the Baltic eels need to concern the migration system for the European eels ? I fail to find any logic in such reasoning.

Tucker then proceeds by putting the following question: "The eels if they survived would be abundant. Why have they never been taken by research vessels in the open Atlantic or by the intensive fisheries along the Continental Slope ? Are agility and this or that depth of swimming adequate explanations ?" I can adduce the following evidence in reply to this question.

Despite the alleged rapid degeneration the silver eel is an agile and 'clever' fish, which is extremely difficult to catch. In the IJsselmeer, on which I have worked as fisheries biologist for fourteen years, focusing mainly on eel problems, the only practical way to catch silver eels is with stationary gear, that is, fyke nets. With eel trawls, silver eels cannot be caught, though such nets are very suited to the capture of younger stages. Using the newly improved IJsselmeer eel trawl—especially designed and suited for catching eels in huge quantities—in the area along the Afsluitdijk we did not catch one single silver eel, notwithstanding the fact that the area must have teemed at that time with silver eels according to the catches made with fyke nets in the immediate vicinity.

Now the IJsselmeer is a shallow body of water, where silver eels abound, and use was made of a small meshed net equipped with two non-returning funnels. These conditions contrast sharply with those in the open and much deeper seas and oceans where silver eels do not concentrate but are sparse and gradually disperse. Fishing is carried out here with dragged gear, which we already know is not capable of catching silver eels even if the eels do not swim at "this or that depth" but would move along the bottom, as Tucker obviously supposes, but of which we are not at all sure. Further, the sea trawls are not equipped with non-returning funnels and have a mesh size in the cod-end of about 7 cm., big enough to offer even the biggest eel the best chance for escape. No fisheries expert acquainted with these details could expect the catch of a single silver eel in open sea.

If on the contrary the European silver eels die on the Continental Shelf, as Tucker presumes, millions and millions of dying and dead silver eels would occur locally on the sea bottom year after year. Undoubtedly such eels incapable of escape would regularly be scooped up by the numerous trawls scraping the sea bottom. As this does not happen we are forced to conclude that silver eels do survive their trek over the Continental Shelf. It cannot even be supposed that they die in deeper waters in the vicinity of the Continental Shelf, for such deaths will not occur at a given spot or depth but will be scattered over quite a vast area, considering the distances to be covered and the range in the maturating process.

A further argument of Tucker is that there are several deeps in the Mediterranean and the Atlantic Ocean, which offer conditions apparently identical to those of the Sargasso Sea; yet eels do not spawn there. I would point out that we do not know anything of the conditions for reproductive activities required by the eels; moreover, Tucker's argument is of the same type as the following: Scandinavian chaffinches in reality observed to hibernate in Ireland will have to migrate over England (which indeed is what happens); but since these birds do not hibernate in England, which offers conditions apparently identical to those in Ireland, it is highly improbable that they will hibernate in Ireland.

Tucker's discussion of the conditions which the American silver eels meet has—as I have already stated—no relation to the achievements of the European silver eels.

Later in Tucker's article are some statements which are not backed up by any substantial data. This also applies to the 'evidence' which is supposed to show the 'debility' of the European silver eel which is 'obliged' to drift passively down stream with the currents. However inactive they are according to Tucker, they are without any doubt very capable of escaping a highly specialized eel-fishing gear dragged through the water with a speed of several miles per hour. Apart from this we must reckon with the possibility that silver eels will be dragged along by the current in the direction of the Sargasso Sea, for a fair current is running in the opposite direction under the Gulf Stream at a depth of some 2,800 m., showing velocities up to 17 cm./sec. (that is, about 15 km./day)[2-4]. I wonder whether Tucker has been aware of this fact.

Tucker discusses some consequences—with rather far-fetched explanations—of the supposed non-return of the silver eels to their spawning places. In this respect I might direct attention to the necessity of constant hydrographical features, especially water temperatures, in the Sargasso Sea from year to year and that during scores of centuries (cf. also ref. 5). It is difficult to believe in such a feature, for the rather short period for which records are available allows us already to conclude that hydrographical conditions are not constant at all but fluctuate quite considerably in the oceans. Therefore one cannot assume with Tucker that a constancy of water temperature has been the guiding factor in the eel's reproduction.

Finally I would direct attention to Tucker's statement that: "The proposition of Schmidt[6]

(p. 204, lines 20–40: How do masses of larvæ in the Western Atlantic sort themselves out . . . . ?) has led to misunderstanding especially among lay authors".

It is quite incomprehensible why such a simple question should lead to misunderstanding, but anyhow it would have been fairer also to quote Schmidt's own answer: "In the main, the question is no longer difficult to answer. In the case of the American eel, the pelagic larval stage is terminated in about one year; . . . . It is otherwise with the European eel, which takes nearly three times as long over its larval development, as a result of which practically all of them are far away from the Western (American) portion of the Atlantic when the time comes for them, as elvers, to seek the coasts".

Surely, there can be no difficulty in accepting the fact that only fully grown leptocephali after having arrived on the slope of a Continental Shelf will stay there. After having completed metamorphosis they will continue their migration as elvers. The sorting out of larvæ off America is in my opinion quite plausible: the fully grown larvæ, that is, those of the American eel, respond to continental conditions and stay; all the others, that is, those of the European eel, with still two years growth ahead, do not respond, and hence are carried on by the Gulf Stream.

I believe that the meaning of all this is quite evident: the edges of the Continental Shelf constitute the area where tidal streams begin. Simultaneous with metamorphosis into the elver stage, the animals change their behaviour in such a way that it enables them to respond to, and take advantage of, the possibilities which the tidal currents offer them, as Creutzberg[7] has recently discovered.

For the sake of completeness I wish to remark that this is not the only known case of eels staying for some time in a transition area, next changing their behaviour pattern in such a way that they will respond to the newly encountered conditions and then continuing their migration. I discovered myself[8] that this is what happens when elvers migrate from sea into fresh water. The well-known metamorphosis from eel into silver eel is also a clear indication that the eel is a real master in the opportunistic art of changing habits and taking advantage of new conditions.

It will be clear from the foregoing discussion that Tucker's claim that his hypothesis is at parity with Schmidt's cannot possibly be supported by me. I still feel that Schmidt is right in his opinion. Concerning the still rather mysterious orientation of silver eels towards the Sargasso Sea, I am inclined to assume that silver eels, having a tendency to develop into a deep sea fish[9–10], are provided with an orientation mechanism directed westward. After leaving the European Continental waters in a westerly direction, many of the silver eels will inevitably meet the deep Atlantic current under the Gulf Stream but in opposite direction. When this happens I do not see any reason why the silver eels should not make use of this current, which will guide them afterwards towards the Sargasso Sea.

Such a journey might be of some 7,500 km. length. Supposing that silver eels will swim at a low speed, for example, some 50 km./day, of which they undoubtedly are capable[11], it will take them only about 150 days to reach their destination. We may be sure that such an effort exerted during that rather short period will be far from demanding the utmost of the animals and will undoubtedly leave enough reserve material to allow an ample development of the gonads.

C. L. Deelder

Dr. Deelder is incorrect in referring to the American silver eel. This phase has not yet been observed, and the migratory stage is known as the bronze or black eel[1,2]. I understand from Dr. W. E. Frost that Dr. V. D. Vladykov recently identified the bronze phase as an intermediate stage between the yellow and silver in British eels.

The apparent maintenance of condition in 'stored' silver eels has already been discussed[3], together with the check on maturation imposed by artificially enforced life in fresh water[1]. 'Putte', the eighty-eight year-old Swedish eel, was in only partial nuptial dress when it died[4]. But under these conditions reserve fat, normally used for gonad maturation, locomotion and physiological (osmoregulatory) work[3], is available for swimming only and restricted swimming at that. It is not sufficient to observe vaguely that stored eels remain active and healthy and then claim that this "demonstrates irrefutably that silver eels are able to move over huge distances". We need concrete data on distances swum, speeds, weight-losses and analyses, preferably in salt not fresh water, and in the meantime it is more material that eels make the Baltic run at average speeds of between 5 and 10 miles per day and lose up to 20 per cent of their weight on the way[3,5].

The migrating bird argument is logical in itself but fallaciously applied. It is possible *a priori* to postulate and experimentally to demonstrate alternative methods of navigation in birds, and birds are known to arrive. It is possible *a priori* to reject all visual navigational aids in eels and, from our present knowledge of physics, oceanography and physiology, it is not possible to postulate any system other than one involving passive transport and inherent reactions to temperature and salinity gradients. Such a system could easily direct a majority of the American eels[1], but not the European: and European eels are not known to arrive.

"The fate of the Mississippi eels need not concern us"[1]. I was not forced to any conclusion whatsoever. Having shown a simple return route for the bulk of the American population I judged it immaterial and prodigal of space to deal withthe complicated Gulf of Mexico current system. Those who wish may study Dietrich[6] and evacuate their Mississippi eels through the Florida Current or through the more circuitous bottom currents of the Gulf and Caribbean. It is sufficient that we have put the major part of the American eels on to the spawning ground; we cannot devise any system that will put any section of the European population on to theirs.

Dr. Deelder's point about the IJsselmeer silver eel fisheries is well taken.

There is no real difficulty about the concealed mortality of silver eels in the sea, any more than there is with the normal mortality of herring, mackerel and all the other marine fishes. The sea has her predators to remove her sick, and her scavengers to keep her clean.

Since my comments on the fitness of the silver eel for migration have caused so much misunderstanding, I will now restate them.

The word 'debility' has been objected to by many other critics[3] besides Dr. Deelder, always through misinterpretation of its single appearance. The original text[1] reads: ". . . the debility of the (European) eel which is obliged to drift passively downstream in the current is due to demineralization . . . remineralization and resumed liveliness occur when the eel reaches the sea". Dr. Deelder chides me for lack of supporting data; I cited Bertin[7] (intending him to be read), who in turn gives a summary and bibliography of a dozen relevant papers by Fontaine and his school; both these authors also employ the word 'débilité' in the same context as I do, in relation to the late freshwater condition. There is no need for Dr. Deelder to attack with his IJsselmeer story; and is not the IJsselmeer still highly brackish ?

The adequacy of the stored food-reserves to provide for the journey is open to speculation[1,3,8]. The vitality of silver eels in inshore waters, re-affirmed by D'Ancona[8], Jones[3] and now Dr. Deelder, is immaterial to the problem of the ocean crossing. We are not interested in the condition of local populations inshore. We want to know the state of the residual European population by the time it crosses the Continental Shelf and is well on its journey, and we have no direct evidence as to that. But I maintain that the cases already cited[1,3,8], of eels losing weight on the Baltic run; of near-ripe eels, eels with degenerating guts, an eel with a blocked vent, provide material evidence that Baltic eels are too far advanced when only partly on their way. The same argument applies to precocious individuals taken from the Mediterranean. I argue that the condition of these silver eels, at most a few hundred miles from their home streams, is a significant indication of the probable state of the survivors of the whole continental European population when an equivalent distance out to sea.

I have already discussed *Conger conger* as a biological indicator of identical spawning conditions in various deeps in the western and eastern Atlantic and Mediterranean[3]. Dr. Deelder's chaffinch argument is logically and biologically unsound, as well as inapplicable to the present situation, but it is nevertheless worth analysing. The British Isles have only the native *Fringilla coelebs gengleri*, but are invaded each autumn by the related Continental *F.c.coelebs* as a winter migrant; the reverse migration of *F.c.gengleri* does not occur. Competing for the identical ecological niche each sub-species must clearly have some advantage over the other in its normal range. Such competition with members of both sub-species compels *F.c.coelebs* flocks to move on across Britain and into Ireland, where a seasonal increase is noted[9]. Now, there can be no competition for food or territory among spawning eels; there are no breeding populations of *Anguilla* in the eastern deeps; why, therefore should *A. anguilla* make a plainly hazardous migration to an area in which its larvæ must enter into competition with those of at least seven other Apodal fishes ?[2,10]. I think it is destroyed by its own metabolic failure before it reaches any of the likely spawning deeps, near or far.

I am mystified by Dr. Deelder's expressed doubt regarding my knowledge of the counter-current beneath the Gulf Stream; I did, in fact, specify this very current as the likely vehicle for the returning American eels[1]. The said current, running as it does near the foot of the American Continental Shelf, is irrelevant to the European eel problem unless Dr. Deelder postulates a return route via the Norwegian Coastal Current, Jan Mayen, and the Greenland Current, and so along the American eel route, with a greatly increased distance/time factor and a northward movement rather than a westerly one as he now specifically suggests. It is interesting to note here that tagged eels released in the Elbe have recently been recovered off Denmark, indicating a northerly rather than a westerly migration[11]. Dr. Deelder's estimate of likely 'low' migration speeds is, like Jones's[3], much too high in relation to those observed[3,6].

I am aware of the annual fluctuations in hydrographical conditions, but do not think that the broad Atlantic picture has altered sufficiently in (geologically) recent times to affect the validity of the new eel hypothesis. As regards earlier epochs there are further intriguing problems in the origin of the Japanese *A. japonica* population (which is closely related to[12] and may have been derived from the Atlantic *Anguilla* during the last Central American subsidence, or during an opening of the North-West Passage), and in the relation between climate and vertebral numbers of the European fossil *Anguilla*.

There is no need to labour my comment on Schmidt's account of the 'sorting' of the two types of leptocephali. In my general preparatory reading I found that it had been misunderstood and given rise to erroneous reasoning, and attempted a re-statement for that reason. There was no intentional unfairness in not quoting the passage in full to save space; again, the reference was intended to be consulted. Here I would like to correct an impression in certain quarters that my new interpretation of Schmidt's work is in some way derogatory to his memory. Dr. Anton Fr. Bruun, *in litt.*, has generously exonerated me of any such charge. If it were not for the oceanic researches of Dr. Johannes Schmidt and the experimental researches of the late Dr. A. Vedel Tåning, together with their other Danish colleagues, I would not have been able to write a word on this subject. Furthermore, most of the work which has been used in this re-assessment of the Atlantic eel problem was not published during Schmidt's lifetime.

PROTECTION AGAINST ACUTE EFFECTS OF RADIATION BY HYPOXIA

By Dr. PATRICIA J. LINDOP and Prof. J. ROTBLAT
Medical College of St. Bartholomew's Hospital, London, E.C.1

IT is well known[1] that the sensitivity of biological systems to radiation is increased in the presence of oxygen and decreased in its absence. In the case of whole-body irradiation of mammals, Dowdy *et al.*[2] have shown that exposure under reduced oxygen pressure results in a considerable increase of the *LD*50. In the course of a systematic study on the age factor in short-term and long-term effects of radiation[3], it occurred to us that the variation of radiation sensitivity with age, recently reported by us[4], may be associated with an oxygen effect. To test this hypothesis we investigated the survival of mice exposed to acute whole-body doses of radiation under hypoxic conditions. These measurements were carried out during April and May 1959, as a pilot experiment for a more detailed study of this effect in animals of various ages. Since, however, the completion of this investigation will take some time, it may be of interest to report our interim findings.

The mice used were of the same strain (albino *SAS*/4) as in the main experiment[3]. They were exposed in 'Perspex' containers consisting of twin cylinders, each of which could accommodate two mice. By means of tubes leading to a manifold, it was possible, by remote control, to substitute nitrogen for air in one of the cylinders. In this way four mice could be exposed simultaneously, two breathing air or oxygen and the other two nitrogen. To prevent convulsion of the mice while removing the oxygen, the mice were anæsthetized prior to irradiation. The anæsthetic used was pentobarbitone sodium ('Nembutal', Abbott Laboratories, Ltd.), at a dosage of 40 mgm. per kgm., administered intraperitoneally. No anæsthetic was used in the case of mice 1–3 days old, since they were not subject to convulsions under nitrogen. With this procedure we observed no ill effects of either the anæsthetic or the temporary hypoxia. Out of a total of 150 control mice which passed through the procedure of being anæsthetized and/or hypoxia, but without being given a dose of radiation, only two died in the course of thirty days.

The radiation used was the beam of 14-MeV. electrons from our linear accelerator. Electrons rather than X-rays were used to make it possible to deliver the required dose of radiation in a very short time. The mean dose-rate was about 2,500 rads per sec., so that even the highest dose employed could be delivered in less than a second. A broad electron beam was obtained by using an aluminium scatterer near the exit window of the accelerator. At a distance of 1 m., where the mice were placed, the beam was found to be uniform over the whole irradiated area.

For measurement of dose we used a small ionization chamber placed near the mice container. The dose absorbed was determined in two ways: (*a*) by a comparison of the readings of the ionization chamber with a 'Perspex' strip dosemeter which had been calibrated absolutely by a calorimetric technique[5], and (*b*) by calculating the collection efficiency of the ionization chamber and then making a correction for the conversion of e.s.u./c.c. into rads. These methods gave results in very good agreement with each other.

The experimental procedure, as determined by preliminary trials on the reaction of the mice to hypoxia, was as follows. After the container with the mice was placed into position for irradiation, the oxygen content was gradually reduced by admixture with nitrogen. This proceeded for 25 sec., by which time the gas was 100 per cent nitrogen flowing at a rate of 6 l. per min. The mice were kept in this atmosphere for 12 sec.; at the end of this time the exposure was made and the nitrogen immediately replaced by oxygen or air.

Figs. 1 and 2 show the results obtained with mice aged 1–3 days and 4 weeks, respectively. The percentage of the animals dying within 30 days is plotted on probability paper against the dose to which they were exposed. These graphs illustrate the striking protective effect of temporary removal of oxygen. From these and other graphs, the *LD*50 values for the different experiments were determined and are given in Table 1. For the tests with older animals

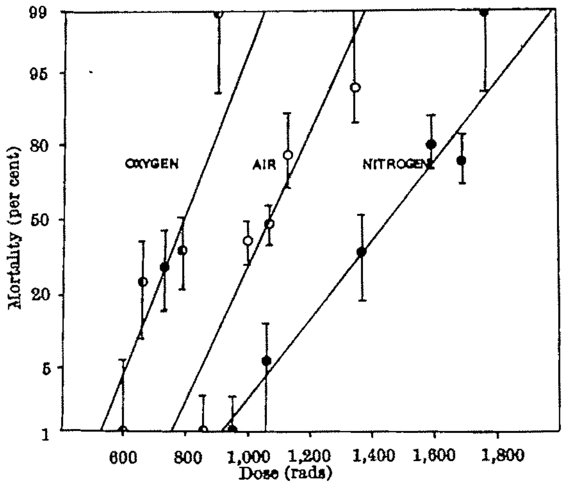

Fig. 1. Percentage 30-day mortality of mice 1–3 days old, breathing different gases, as a function of dose

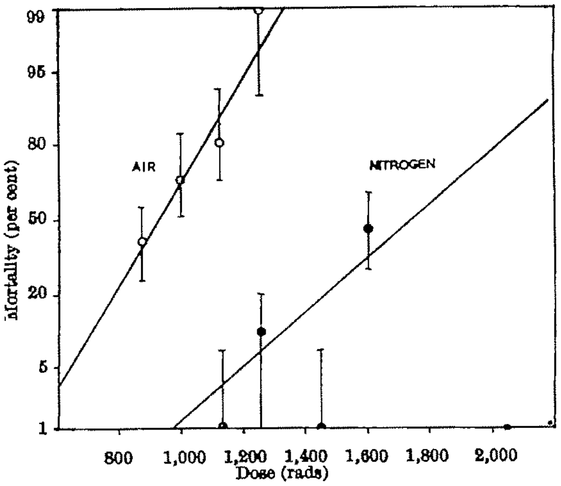

Fig. 2. Percentage 30-day mortality of mice 4 weeks old, breathing different gases, as a function of dose

Table 1. *LD*50 VALUES FOR MICE EXPOSED UNDER DIFFERENT CONDITIONS

Age	X-ray exposure in air (rads)	Electron exposure in :			Nitrogen protection factor
		Oxygen (rads)	Air (rads)	Nitrogen (rads)	
1–3 days	833 ± 24	788 ± 18	1,068 ± 20	1,450 ± 40	1·74 ± 0 07
4 weeks	684 ± 16	—	930 ± 45	1,760 ± 90	2·58 ± 0·15
19 weeks	880 ± 25	—	1,005 ± 65	1,750 ± 150	1 99 ± 0·18
82 weeks	764 ± 20	—	950 ± 100	1,320 ± 120	1 73 ± 0·16

very few mice were available; hence the large experimental errors for these groups.

Table 1 also contains the *LD*50 values obtained previously[4] for mice exposed under the standard conditions of our investigation, namely, using 15-MeV. X-rays at a rate of 7 rads per sec. (The conversion factor used (1 r. = 0·98 rad) was obtained in a direct measurement under the conditions of the experiment.) The last column of Table 1 contains the nitrogen protection factor, that is, the ratio of the *LD*50 at exposure in nitrogen to that under standard conditions.

These results show that exposure of mice under hypoxic conditions produces an entirely different age variation from exposure in air. For example, at 4 weeks of age the *LD*50 reaches a minimum when the mice are exposed in air, but it appears to have its highest value at the nitrogen exposure.

It is not yet clear how the oxygen effect operates in this case, but it may arise from differences in oxygen tension in tissues of animals of different ages. The relatively high *LD*50 value during the first week of life may be the result of a reduced oxygen tension in the neonatal stage, due to incomplete pulmonary ventilation and to circulatory readjustments of early extra-uterine life[6]. Indirect evidence of a lower oxygen tension is provided in our experiment in which the neonatal mice were exposed in an oxygen atmosphere; this gave a considerable decrease of the *LD*50. At normal oxygen tension the change should have been very small.

The increase of the *LD*50 for mice older than 4 weeks could also be due to a gradual decrease with age of the oxygen tension in tissues, starting from about 4 weeks. Such a decrease might result from changes with age in vascularity, diffusion coefficients and pulmonary ventilation. It is known that large gradients of oxygen tension exist in tissues, but there is little evidence that they change with age; there is also no evidence to the contrary. Another possible explanation of the results obtained with the hypoxic mice is that the time required to reduce to a given level the oxygen tension in the vital tissues, such as bone marrow, may vary with age, becoming longer the older the animal. This would mean that in our experiments the older mice were exposed under less hypoxic conditions than the younger ones. Experiments are now in progress to measure directly the oxygen tension in various tissues in mice of different ages.

Referring to Table 1, it will be noticed that the *LD*50 values obtained in air in the present experiment are, in all cases, higher than those obtained previously. The main differences between this and the previous experiment are: (*a*) electrons were used instead of X-rays; (*b*) the dose-rate was much higher; (*c*) the animals were, in some cases, anæsthetized. It is difficult to see how the change from X-rays to electrons could make a significant difference, particularly since the dose absorbed within the body of the animal was uniform within a few per cent. In other experiments, too, we have found no difference in the effects produced by X-rays or electrons at comparable dose-rates.

There remain the two other factors. We have evidence that anæsthesia does reduce sensitivity to radiation, probably because of a lowering of the oxygen tension in tissues[7]. This may account for some of the increase in the *LD*50 in animals exposed in air.

With regard to dose-rate it is known that over a large range of dose-rates the sensitivity to radiation increases with increasing dose-rate[8,9]. Our own preliminary investigations at high dose-rates do not show an increase of sensitivity; there are, in fact, indications of a decreasing sensitivity with dose-rate. Such a decrease, if confirmed, might occur for the following reason. Oxygen in the tissues is consumed during irradiation, but is normally replenished from the oxygen in the blood. If, however, the dose is delivered at a very high rate, the loss due to the first fraction of the dose may not be made up quickly enough and the remaining dose is given to the animal while some sensitive parts of it are under hypoxic conditions. Dewey and Boag[10] have reported such an effect in bacteria; the results of Kirby-Smith and Dolphin[11], who studied the chromosome breakage of *Tradescantia*, may also be due to a similar effect. If the same applied to mammals, then both factors, the anæsthetic and the high dose-rate, would really be oxygen effects. It is quite likely that the dose-rate effect would become manifest only in combination with an anæsthetic or a naturally low oxygen tension in tissues.

Further experiments, particularly using animals of more age-groups, are needed to elucidate these problems. Even from these preliminary results, however, it is obvious that age is an important factor in the protective action of hypoxia as well as in the acute effects of radiation. The same may apply to long-term effects. We have indeed evidence (to be published shortly) that long-term effects of radiation, such as shortening of life, show a similar variation with age at irradiation.

We wish to thank Mr. A. L. Bradshaw and Mr. G. S Innes for their help with the dosimetry and Miss Jeanne Moody and Mr. J. L. Bounden for their constant help with the experiment. We are also indebted to the Nuffield Foundation, the British Empire Cancer Campaign, and the Endowment Fund of St. Bartholomew's Hospital for grants which have made this work possible.

INTERPRETATION OF POTENTIOMETRIC TITRATION OF H-MONTMORILLONITE

By Dr. A. M. POMMER and Dr. D. CARROLL
U.S. Geological Survey, Washington, D.C.

It has been observed[1] that the pH titration curves of hydrogen clays with strong monovalent bases have various characteristics, such as variation in steepness of slope in different parts of the curve. Variations have also been noticed for the kind of clay mineral, the amount of mineral in suspension, and the cations used to produce neutralization. Garrels and Christ[2], using original data of Marshall and Bergman[3] for the titration of the clay mineral (beidellite) in the Putnam silt loam soil, have shown that the neutralization curve of pH plotted against concentration of potassium hydroxide appears similar to that of two independent clay acids. They termed the two substrates the C^- (centre or interlayer site) and E^- (edge site). Blackmon[4] calculated exchange constants for the C^- and E^- sites of beidellite and 'illite' for K^+, NH_4^+ and Na^+. Cations are more strongly held by the E^- than by the C^- sites.

Neutralization curves obtained with different clay minerals show variations that can, in part, be attributed to the ratio of C^- to E^- sites. Differences in the bonding energy of monovalent and divalent cations introduce another variable that is expressed by the shapes of the titration curves. The resemblance between neutralization curves of some clay minerals and of humic acid suggested that a similar explanation would apply to these two kinds of substances, that is, the neutralization of a polymeric electrolyte.

Katchalsky and Spitnik[5] showed that the neutralization of a polymeric electrolyte could not be described by the Henderson–Hasselbalch equation:

$$pH = pK_a + \log \frac{\alpha}{1 - \alpha}$$

where pK_a is the negative logarithm of the ionization constant of a weak acid, and α is the degree of neutralization. Katchalsky and Spitnik ascribe this deviation to the uncoiling of the polymer chains during titration because weak hydrogen bonds are replaced by strong cationic bonds as ionization proceeds. These authors have further shown that a generalized Henderson–Hasselbalch equation of the form:

$$pH = pK_a + n \log \frac{\alpha}{1 - \alpha}$$

where n is a constant, will describe the titration of a polymeric electrolyte. It was therefore of interest to determine whether the titration of H-montmorillonite with sodium hydroxide, which also involves a change of dimension of the substrate due to swelling, was similar to that of humic acid.

A sample of montmorillonite from Chambers, Arizona (A.P.I. Standard No. 23, ref. 6), was converted to the H-form by treatment in 1 N hydrochloric acid by the method of Aldrich and Buchanan[7], with the omission of the final treatment with an ion-exchange resin. Care was taken to remove all traces of chloride by repeated washing and centrifugation. No aluminium was found in the supernatant water in contact with the H-montmorillonite, although this water had a pH value sufficiently low for aluminium to be in solution. This suggests that no aluminium was in the exchange positions. Titrations were made by a discontinuous method in which 65-mgm. samples of montmorillonite were suspended in 5 ml. water and increasing multiples of a 0·02-ml. increment of 0·1 N sodium hydroxide were added. The maximum volume of sodium hydroxide used was 1·2 ml. Additional water was added, when required, to make a constant volume of 6·20 ml. for each sample. The pH value was measured repeatedly until it remained constant for about six weeks. Titration curves were plotted semi-logarithmically. The volume of titrant added was entered on the logarithmic ordinate, and the pH on the linear abscissa. The result is shown in Fig. 1.

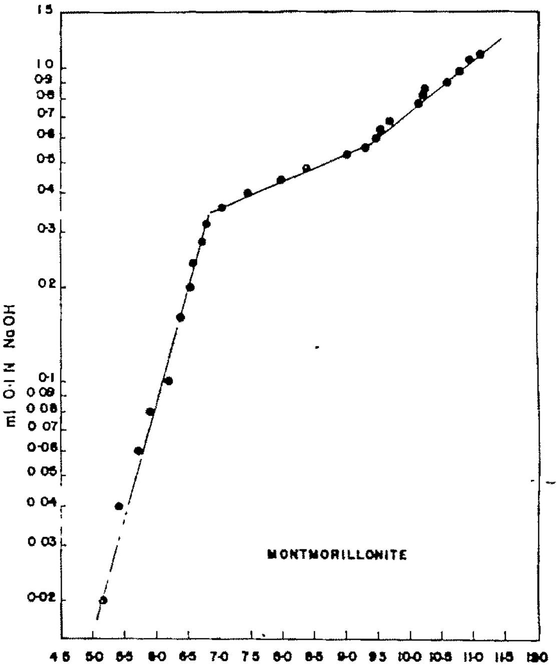

Fig. 1 Titration of H-montmorillonite with sodium hydroxide

The plot was made in this way for the reasons set out below. Gran[8] has shown that if a dibasic weak acid is titrated with a strong base the following relation holds before the first equivalence point is reached:

$$10^{-pH} = \frac{K_a}{V} (V_1 - V)$$

Here K_a is the first ionization constant of the acid, V is the volume of base added, and V_1 is the volume necessary to reach equivalence. Upon logarithmic transformation this relation yields:

$$pH = \log V - \log K_a - \log (V_1 - V)$$

This equation can be rearranged to:

$$pH = \log V - \log K_a - \log V_1 + \log (1 + \frac{V}{V_1})$$

a relation which shows that a plot of pH against $\log V$ will yield a straight line except for a deviation contributed by the last term in this equation. Evaluating $\log (1 + V/V_1)$ we find that, at the start of the titration, $V = 0$ and $\log (1 + V/V_1) = 0$, whereas at the point at which equivalence is reached, $V = V_1$ and $\log (1 + V/V_1) = \log 2 = 0{\cdot}30$. Hence, a plot of $\log V$ against pH over this region will deviate from linearity by 0·30 pH units. This small deviation may be neglected.

In the region between the first and second equivalence points, Gran[8] showed that:

$$10^{-pH} = K'_a \frac{V_2 - V}{V - V_1}$$

where K'_a is the second ionization constant of the acid and V_2 is the volume of base necessary to reach the second equivalence point. By using the same approach as before, this equation can be rewritten as:

$$pH = \log (V - V_1) - \log K'_a - \log V_2 - \log (1 + \frac{V}{V_2})$$

and it is possible to plot pH against $\log (V - V_1)$ as essentially a straight line.

A plot of $\log V$ against pH will also yield a straight line. Gran[8] has shown that, after the second equivalence point has been passed:

$$10^{pH} = \frac{C_B}{f_H K_w (V_0 + V)} (V - V_1)$$

where C_B is the concentration of base, f_H is the activity coefficient of the hydrogen ions, K_w is the ionization constant of water, and V_0 is the volume at the start of the titration. Again, it can be expected from this relation that also in this region a plot of $\log V$ against pH will yield a straight line.

If, then, $\log V$ is plotted against pH when a dibasic weak acid is titrated with a strong base, three approximately straight lines should appear. These lines should intersect at the equivalence points. A plot of V against pH, based on the discontinuous titration of H-montmorillonite showed that this is so for this clay mineral (Fig. 1). It is possible to estimate from the equivalence points in Fig. 1 that the cation exchange capacity of the first clay acid, presumably representing the interlayer (C^-) sites, is about 50 m.equiv./100 gm., and that the cation exchange capacity of the second acid, presumably representing the edge sites (E^-), is about 40 m. equiv./100 gm. The total exchange capacity of this H-montmorillonite as determined by this method is about 90 m. equiv./100 gm. The exchangeable cations remaining on this H-clay, as determined by the Association of Official Agricultural Chemists method[9], were 34 m. equiv./100 gm., and the total exchange capacity of the original montmorillonite was, therefore (90 + 34 m. equiv.)/100 gm. or 124 m. equiv./100 gm., a value comparing closely with that of ~ 120 m. equiv./100 gm. reported for this mineral[10].

A plot of $\log \alpha/(1 - \alpha)$, values for which were easily obtained after the exchange capacity was determined, against pH over the region of the neutralization of the first acid gave a straight line with a slope of 1 and an intercept of 6·4 (Fig. 2a). A few points in the region where $1 - \alpha$ approached zero could not be used in the construction of this line. It appears from the value of the intercept that the ionization constant of the first acid is $10^{-6{\cdot}4}$ and from the slope that the acid behaves as a pure weak acid upon neutralization. A similar plot over the region of the neutralization of the second acid (Fig. 2b) gave a straight line with an intercept of 8·3, indicating an ionization constant of the second clay acid of $10^{-8{\cdot}3}$ and a slope of 0·7. This shows that the clay acid deviates in its behaviour from that of pure weak acid, and that it can be described by the type of generalized Henderson–Hasselbalch equation used in the titration of polyelectrolytes. The value of n in this case, however, is smaller than 1. The reason for this deviation has not yet been explored.

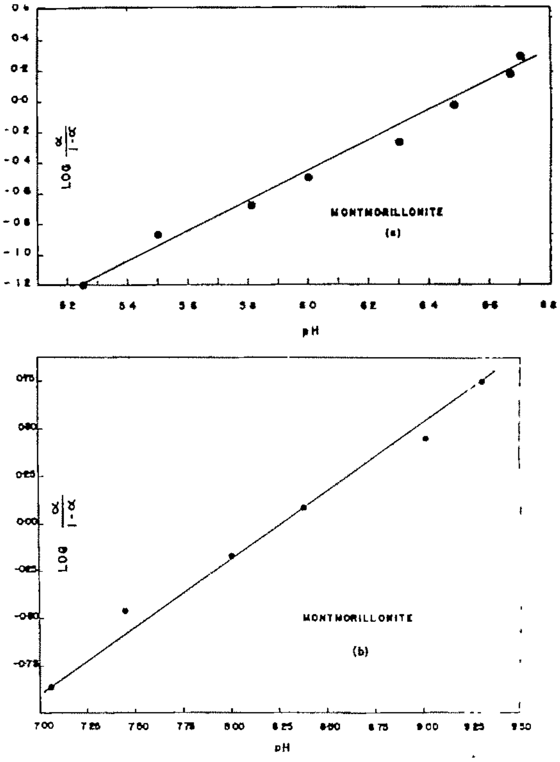

Fig. 2. (*a*) Plot of $\log \alpha/(1-\alpha)$ against pH for first clay acid; (*b*) plot of $\log \alpha/(1-\alpha)$ against pH for second clay acid

We think that plotting the results of discontinuous titrations of H-clays as described is a useful way to characterize their exchange relations. We have made similar titrations for vermiculite and 'illite'. These results, together with that for montmorillonite, will be described in a more comprehensive paper now being prepared for publication.

This investigation was partly supported by the Division of Reactor Development, U.S. Atomic Energy Commission, and publication is authorized by the Director, U.S. Geological Survey.

CHEMICAL AND SEROLOGICAL RELATIONSHIPS OF CERTAIN BACTERIAL POLYSACCHARIDES CONTAINING SIALIC ACID

By Prof. GUY T. BARRY, TIEN-HU TSAI and FRANCIS P. CHEN

University of Tennessee Memorial Research Center, Knoxville, Tennessee

SINCE the composition of the polysaccharide, colominic acid, obtained from an *E. coli* organism, was established[1] as poly N-acetylneuraminic acid (ovine sialic acid), reports have appeared describing other bacterial polysaccharides that contain a sialic acid[2,3]. One of these substances, the specific hapten of group *C N. meningitidis*[2], is also largely constituted of units of O-sialic acid. Thus, it appeared that colominic acid may be produced by species of bacteria other than *E. coli*. It was of interest to ascertain by agglutination tests whether the various species of bacteria known to produce polysaccharides rich in sialic acid showed any relationship to each other. In addition, a study was made of the chemical and serological properties of four polysaccharides containing sialic acid obtained from different bacteria.

All enteric bacteria were grown in sterile culture. The bottles containing 15 l. of suitable medium were incubated (with aeration) at 37° C. for 18 hr. The bacteria were killed by the addition of 100 ml. of chloroform and harvested by centrifugation. The cells were suspended in 100 ml. of water and collected as before. The washed bacteria were suspended in 100 ml. of water and lyophilized.

N. meningitidis bacteria were cultivated at 37° C. for 18 hr. on 10 sterile blood agar plates. The cells were carefully removed by flushing each plate with 5 ml. of distilled water. The cells were collected by centrifugation, washed, and lyophilized.

Sialic acid analyses were performed on the dried bacteria, employing a modification of Werner and Odin's method[4]. N-acetylneuraminic acid served as the standard and the figures recorded represent typical values, expressed as a percentage of dry weight: *Escherichia coli* 01 : *K*1 : *HNM* (0·27); *E. coli* 02 : *K*1 : *HNM* (0·46); *Neisseria meningitidis* group *C* 1908 (0·64); *N. meningitidis* group *C* 1935 (0·26); *Citrobacter freundii* (1·92); *Salmonella dahlem* (1·19); and *S. djkarta* (0·51).

Antibacterial antisera prepared against the *K* antigen of the *E. coli* strains were obtained by Edwards's procedure[5]. *N. meningitidis* antibacterial antisera were prepared by Rake's method[6]. Edwards and Ewing's method[7] was used for production of *H* antigen antibacterial antisera prepared against the *C. freundii*, *S. djkarta* and *S. dahlem* strains.

The results of the agglutination tests are given in Table 1. It is to be noted that all the bacteria show agglutination in homologous antisera. The *E. coli* 01 : *K*1 : *HNM* and the group *C N. meningitidis* 1908 strains are unrelated by cross agglutination tests to each other or to any of the other strains examined. The cross agglutination tests reveal a relationship between the two *Salmonella* strains and

Table 2. Composition of Polysaccharides containing Sialic Acid obtained from Various Bacteria

Source organism	Substance isolated	Empirical formula	Elemental analysis					Per cent sialic acid
			C	H	N	O	CH_3CO	
E. coli 01 : *K*1 : *HNM*	Colominic acid	$(C_{11}H_{19}NO_9)_n$	42 83	6·46	4·79	45·97	14·45	99 0
E. coli 02 : *K*1 : *HNM*	Colominic acid	$(C_{11}H_{19}NO_9)_n$	43·75	6 36	4·71	45·18	13 88	98·5
N. meningitidis group *C* 1935	Group *C* hapten	$(C_9H_{16}NO_8)_n$	41·80	6 66	5·32	46·24	11·62	85 0
C. freundii	Polysaccharide	$(C_{15}H_{28}N_2O_{11})_n$	44·19	7·16	6·86	41 79	10 57	36·2

between each of these with the *C. freundii* organism. Cross agglutination tests, not recorded here, show that *E. coli* 02 : *K*1 : *HNM* is related to *E. coli* 01 : *K*1 : *HNM* and to no other strain listed in Table 1. Furthermore, a group *C N. meningitidis* strain known as 1935 is related only to the group *C N. meningitidis* 1908 strain and to none other listed here. Therefore, on the basis of these tests the above bacteria which produce polysaccharides that contain sialic acid can be divided into three groups.

Polysaccharides containing sialic acid were isolated from members of each group. Colominic acid was isolated from the culture media of *E. coli* 01 : *K*1 : *HNM* and 02 : *K*1 : *HNM* bacteria by a previously reported procedure[8]. This procedure, with a few modifications, was employed for the preparation of a new polysaccharide that contains sialic acid isolated from the culture medium of the *C. freundii* organism.

The results of the chemical analyses are recorded in Table 2. It is to be noted that colominic acid isolated from either *E. coli* 02 : *K*1 : *HNM* or 01 : *K*1 : *HNM* bacteria has similar elemental compositions and sialic acid content with one acetyl group for each nitrogen atom. Furthermore, identical infra-red absorption spectra and optical rotation values are obtained. N-acetylneuraminic acid is the only substance found in hydrolysates of either polymer. The calculated empirical formulæ support the belief that O-sialic acid ($C_{11}H_{19}NO_9$) is the sole chemical constituent present in these polysaccharides.

Group *C* hapten isolated from group *C N. meningitidis* 1935 strain contains about 85 per cent sialic acid. An empirical formula $(C_9H_{16}NO_8)_n$ also fits the elemental analytical data reported[2].

The group *C* hapten 1908 used in the present study contains 70·4 per cent sialic acid and a small amount of protein[9]. Hexosamines[10] are absent. The results of these tests indicate that a portion of the group *C* hapten is undetermined.

The *C. freundii* polysaccharide contains 36 per cent sialic acid and one of the nitrogen atoms is believed to be acetylated. Hexuronic acids are absent and only trace amounts of protein can be detected. About 21 per cent of hexosamine is present. Phosphorus is absent. Thus, half this polysaccharide, rich in nitrogen, remains to be characterized.

All four polysaccharides readily decompose upon heating in dilute mineral acid to form humin. Colominic acid does not form precipitins with antibacterial antisera prepared against *E. coli* 01 : *K*1 : *HNM*, 02 : *K*1 : *HNM* or group *C N. meningitidis* 1908 and 1935 bacteria. The group *C* hapten yields a precipitin with the group *C N. meningitidis* antibacterial antisera in a dilution of 1 part in 10^6 but not with the *E. coli* 01 : *K*1 : *HNM* or 02 : *K*1 : *HNM* antisera. Incubation of colominic acid with *N. meningitidis* 1908 or 1935 antisera fails to block precipitin formation by the group *C* hapten. Incubation of group *C* hapten with *E. coli* 01 : *K*1 : *HNM* or 02 : *K*1 : *HNM* antibacterial antiserum followed by the addition of *E. coli* 01 : *K*1 : *HNM* or 02 : *K*1 : *HNM* bacteria does not inhibit agglutination of the cells.

Hæmagglutination tests employing group *C* hapten adsorbed to human O erythrocytes in group *C N. meningitidis* 1908 or 1935 antisera show strong hæmagglutination of the cells. However, no hæmagglutination occurs with *E. coli* 01 : *K*1 : *HNM* or 02 : *K*1 : *HNM* antibacterial antisera. Incubation of colominic acid with either *N. meningitidis* antiserum prior to the addition of the coated erythrocytes fails to block hæmagglutination of the cells. Therefore, it must be concluded that on the basis of the serological tests the group *C* hapten obtained from group *C N. meningitidis* organisms is unrelated to colominic acid obtained from *E. coli* bacteria despite the chemical similarity of the two materials. The absence of a serological relationship suggests differences in chemical linkage between the constituent units.

The *C. freundii* polysaccharide gives a precipitin with antibacterial antisera prepared against *C. freundii*, *S. djkarta* and *S. dahlem* bacteria.

Up to the present time the sialic acids have been found only in Gram-negative organisms. Three polysaccharides containing sialic acid obtained from such organisms—colominic acid from *E. coli*, group *C* hapten from *N. meningitidis* and a previously undescribed material from a *C. freundii* organism—were found to contain different amounts of sialic acid and to be unrelated on the basis of serological tests. Colominic acid remains as a unique material produced only by *E. coli* organisms which possess a *K*1 antigenic serotype[11]. Precipitin tests indicate that a polysaccharide rich in sialic acid obtained from a *C. freundii* organism is related to a similar material produced by *S. dahlem* and *S. djkarta* bacteria. Thus, the occurrence of the sialic acids in various bacterial polysaccharides in different chemical combinations indicates that these monosaccharides are common structural constituents of cells.

This work has been supported by a grant from the U.S. Public Health Service.

We are indebted to Dr. H. Scherp, National Institutes of Health, Bethesda, Maryland, and to Dr. G. Watson, Bowman Gray Medical School, North Carolina, for the sample of group *C* hapten 1908 and for the group *C N. meningitidis* 1908 and 1935 strains.

LETTERS TO THE EDITORS

RADIOPHYSICS

Constant Ionosphere Height for Audio-frequency Propagation

THE wave-form of an atmospheric, resulting from a distant lightning flash to Earth, has variously been interpreted in terms of pulse reflexion between parallel or concentric conducting Earth and ionospheric layers[1,2] or as pulse dispersion during propagation in the region between these same layers[3]. Recent papers[4,5] have discussed the equivalence of these approaches. In each case the Earth–ionosphere separation and the storm distance are the principal determinants of the positions of the peaks of the trace. Within certain limits these propagation parameters may be estimated from the observed wave-forms.

Smooth type wave-forms[5] of distant Atlantic origin, received both by day and night, have recently been studied extensively at Nottingham. Wave-form analyses of 70 traces, using wave-guide concepts, together with distance estimates in the range 1,750–5,000 km., kindly provided by the Meteorological Office Sferics network, have permitted estimation of the effective ionosphere height both by day and for several hours after sunset in the case of winter-time storms. A constant ionosphere height of 83 ± 2 km. irrespective of the time of day was the most reasonable conclusion from the results available, with no significant variations from this mean value for individual recording periods and no suggestion of a systematic variation with the onset of night-time conditions even up to 4 hr. after local sunset. This suggests a fundamental difference between smooth and reflexion type wave-forms, for the latter of which various workers[1,2] have reported an increase in effective height at night.

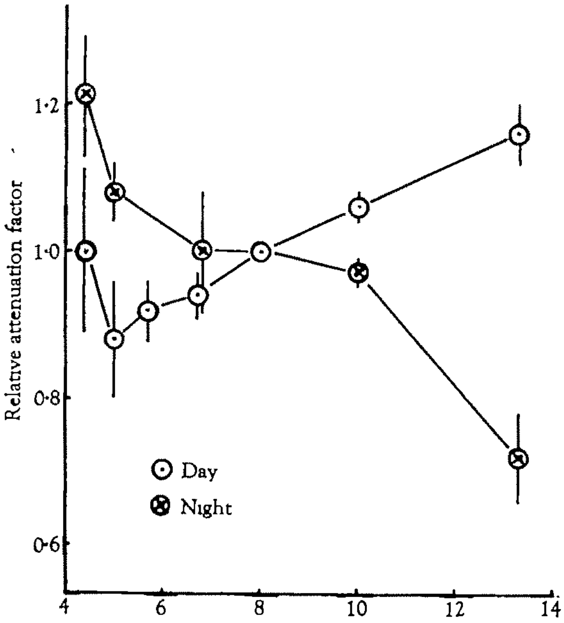

Fig. 1. Attenuation factors. (Fractional changes per 1,000 km. relative to 8 kc./s.)

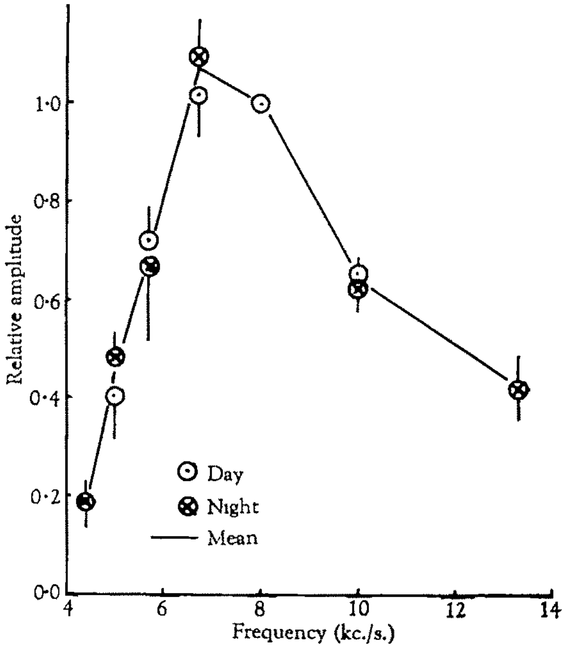

Fig. 2. Average source spectra

An earlier paper[5] has discussed the derivation of relative attenuation coefficients for propagation and the mean amplitude-spectrum at the source from statistical analysis of the oscillation amplitudes throughout the observed wave-forms. For a group of 150 apparently regular smooth type wave-forms, it was found that attenuation factor per 1,000 km. relative to that at 8 kc./s. varied little throughout the frequency-range 4–14 kc./s. A slight systematic increase with frequency was noted by day and a less precise and regular decrease at night (Fig. 1). The corresponding source spectra were indistinguishable (Fig. 2).

The very slight diurnal variation of attenuation in the appropriate frequency band, while unexpected when comparison is made with previous atmospherics measurements[6], might have been predicted from the very close similarity of day- and night-time forms of this restricted group of smooth type wave-forms. The identity of the day and night source spectra provides gratifying confirmation of the analysis and the significance of its conclusions.

Measurement of Solar and Diurnal Effects in the High Atmosphere by Artificial Satellites

IN a previous investigation[1] atmospheric densities had been derived from the orbital elements[2] of the satellites 1958 β 2, 1958 α, 1958 δ and others, and reduced to the mean altitude of the perigee by means of the Kallmann–Juncosa[3] model. A good correlation exists between atmospheric fluctuations and the 20-cm. solar flux curve[4]. This is apparent not only from the 'monthly' fluctuations[5] but also from long-period variations extending over several months. For altitudes of 660, 350 and 210 km. the relation between density and solar flux is approximately linear for values of solar flux S between 100 and 240×10^{-22} W./m.^{2} c./s. To demonstrate the effect it was necessary to separate quantitatively the suspected diurnal fluctuations and the fluctuations caused by variable solar radiation. A preliminary investigation was carried out using the geocentric angular distance perigee–Sun which had already been employed by Jacchia (see ref. 2) for comparison with the satellite data. The angular distance proved very useful so long as no separation of the diurnal and terrestrial effects was possible. One expected, however, the atmospheric density to be dependent on $\Delta\alpha = \alpha_\pi - \alpha_\odot$, $\Delta\delta = \delta_\pi - \delta_\odot$ and the geocentric latitude ψ of the perigee (where α is right ascension, δ is declination, π is perigee, $\odot$ is Sun).

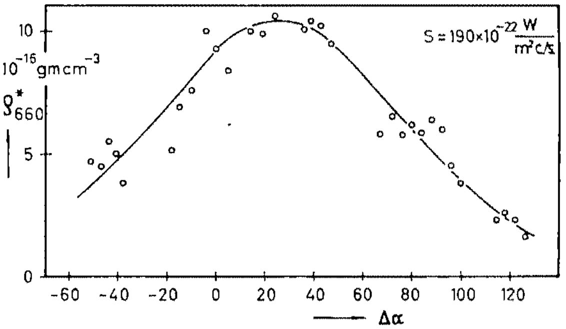

Fig. 2. Dependence of atmospheric density on $\Delta\alpha = \alpha_\pi - \alpha_\odot$ in the equatorial zone (diurnal effect)

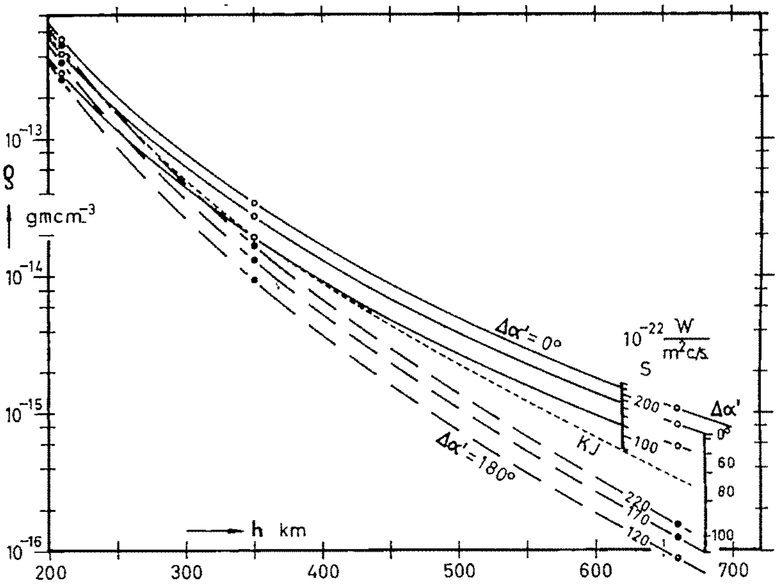

Fig. 3. Model of air density derived from the orbital elements of the satellites 1958 β 2, α and δ 2 with solar and diurnal effects ($\Delta\alpha' = \Delta\alpha - 25° = 0°$ and 180° corresponding to 13h. 40m. and 1h. 40m. local time). The short dotted line (*KJ*) represents the model by Kallmann and Juncosa (ref. 3)

A separation of the diurnal effect (dependence on $\Delta\alpha$) is now possible for the satellite 1958 β 2, for which the best observational data are available. The result is presented in Figs. 1 and 2. For this purpose the atmospheric density data were first reduced to a standard value of the solar 20-cm. radiation ($S = 190 \times 10^{-22}$ W./m.^{2} c./s.). This was possible because of the linear relation between atmospheric density and 20-cm. radiation which had already been found[1]. The resulting values were drawn in a $\Delta\alpha$, $\Delta\delta$ co-ordinate system and the lines of constant density determined. They are shown in Fig. 1 for values of 2, 4, 6, 8 and 10×10^{-16} gm. cm.$^{-3}$. For simplification in the diagram, the individual values are represented in groups (see right-hand corner of diagram). The dotted line represents $\delta_\pi = 0$ ('perigee above the equator'). The lines of constant density are strongly influenced by the scattering of the individual values. For this reason only the general appearance of the curves can be considered reliable. From this appearance one can deduce two effects: (1) a seasonal effect (dependent on the declination of the Sun) with a maximum value of atmospheric density at $\Delta\delta = 0$; and (2) a terrestrial effect with a maximum value of the density above the equator. The two effects are superposed.

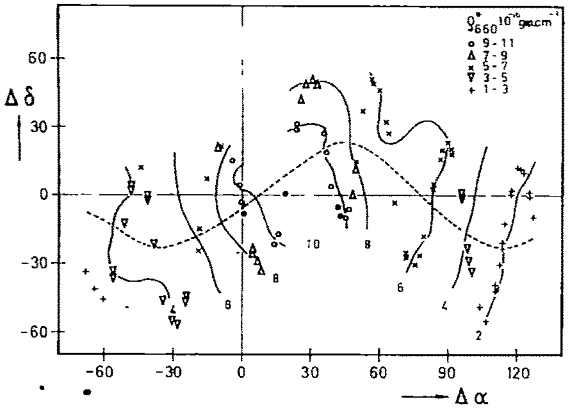

Fig. 1. Atmospheric density at an altitude of 660 km. in a co-ordinate system centred at the subsolar point. $\Delta\alpha = \alpha_\pi - \alpha_\odot$, $\Delta\delta = \delta_\pi - \delta_\odot$ (α, right ascension; δ, declination; π, perigee; $\odot$, Sun). The values of atmospheric density are reduced to a flux of solar 20-cm. radiation of $S = 190 \times 10^{-22}$ W./m.^{2} c./s.

Most conspicuous is the strong diurnal variation of $\Delta\alpha$ (Fig. 2) and the phase shift of about 25° corresponding to a maximum value of atmospheric density around 13h. 40m. true local time. The value of the delay is somewhat uncertain[1]. Using a simplified method for analysing the results, we found[1] a shift of 16°. Wyatt[6] found 23° (1h. 30m.) and an asymmetric diurnal variation. The asymmetry may result from the fact that in his derivation all values were included independent of variations in $\Delta\delta$ and ψ. If only values of the density from a narrow zone around the equator are used with both

$|\psi| < 30°$ and $|\Delta\delta| < 30°$, a much smaller scattering of the results is found. In our earlier paper (ref. 1, Fig. 3), some points did not fit the general curve. It was found that all of them represent density values for which $|\Delta\delta| > 30°$.

Using atmospheric densities as derived in our earlier communication[1] for altitudes of 210, 350 and 660 km. we obtain a density model with solar and diurnal fluctuations as shown in Fig. 3. The scale-heights of the atmosphere according to Kallmann and Juncosa[3] on which the computations were originally based are eliminated from the final result by means of an iteration process (see ref. 1).

In Fig. 3 the three upper curves (solid lines) are valid for $\Delta\alpha' = \Delta\alpha - 25° = 0°$ (13h. 40m. local time); the three lower (dotted) curves are valid for $\Delta\alpha' = 180°$ (extrapolated values). In each group the lowest of the three curves corresponds to a value of $S = 120$, the middle curve to $S = 170$ and the upper curve to $S = 220 \times 10^{-22}$ W./m.^{2} c./s. of the solar 20-cm. radiation. The large density fluctuation between day and night suggests a daily up and down movement of the atmosphere[6].

A layer of constant atmospheric density, for example, would rise from 520 to 660 km. within 6h. according to Fig. 2. The resulting velocities in the vertical direction are about 25 km./hr. The air movements decrease with decreasing altitude and at 200 km. become insignificant compared with the fluctuation caused by solar radiation. The latter must originate in a layer below 200 km. This suggests that the absorption of solar X-ray radiation in the E-layer of the ionosphere is responsible for them. The scale height $H = \frac{RT}{gM}$ (where R is the gas constant, T is temperature, g is acceleration of gravity, M is mean molecular weight) of the atmosphere and thus the ratio T/M changes strongly with the time of the day but very little with the flux of 20-cm. radiation.

PHYSICS

Natural Radioactivity of Samarium and Neodymium

There seems to exist a discrepancy between the measured value of the alpha-decay half-life of natural samarium (samarium-147) and the theoretical half-life calculated from its measured alpha energy[1]. This may be due to the fact that in most ion-chamber measurements of samarium-147, heavy natural alpha-emitters with much higher energies have been used as standards, which leads to great difficulties because of the non-linearity of the ionization process.

In this investigation thin samples containing about 50 μgm./cm.^{2} of natural samarium, 0·3 μgm./cm.^{2} of natural uranium and 0·5 μgm./cm.^{2} of elemental boron were analysed in a grid-type ionization chamber in the presence of a thermal neutron flux of $1·5 \times 10^3$ n/cm.^{2} obtained from a polonium–beryllium source.

The neutrons absorbed by boron gave rise to alpha-particles with energies of 1·797 and 1·474 MeV.[2], respectively, which were recorded photographically together with the samarium and uranium alpha-particles for the purposes of calibration[3].

By the use of exposures several days long, spectra containing 10^4–10^5 pulses were obtained and analysed with a spectrophotometer. The result for the alpha energy of samarium-147 is:

$$E = 2·20 \pm 0·03 \text{ MeV.}$$

which is somewhat higher than the value quoted by W. Jesse and J. Sadauskis[4].

The specific activity of samarium-147 was measured by counting the alpha-particles from 28·9 mgm. of samarium which were vacuum-evaporated on a source plate of diameter 200 mm. Taking into account self-absorption and back-scattering, a value of 7·00 ± 0·3 counts/min./mgm. of natural samarium is obtained, which corresponds to a half-life of $(1·14 \pm 0·05) \times 10^{11}$ yr. for the isotope 147.

An attempt to detect the natural alpha activity of neodymium was made using a 200-mm. source-plate on which 36 mgm. of neodymium were evaporated. In spite of appreciable thorium contamination a weak line was observed at (2·0 ± 0·1) MeV., in agreement with investigations made by the emulsion method[5].

Evaporation Figures on the Surface of Sodium Chloride Crystals

Figures which appear during evaporation on the surface of sodium chloride have already been reported by E. Kern and H. Pick[1], S. Amelinckx and E. Votava[2], and others. Here we report on figures obtained during evaporation experiments which recall similar figures obtained on the surface, for example, of silicon carbide by A. R. Verma[3] and on sodium chloride by Z. Morlin[4].

The annealing of the sodium chloride plates (15 mm. × 5 mm. × 2 mm.) was carried out near the melting point for 4–5 days in a crucible made from sodium chloride single-crystal and covered with a single-crystal plate. Besides the simple-concentric circles seen in Fig. 1 (the small spots on the figure are etch-pits revealed by glacial acid), figures of sharp characteristic contours were obtained (Fig. 2). These may represent Frank–Read sources, which appear at the edges of the sodium chloride plates,

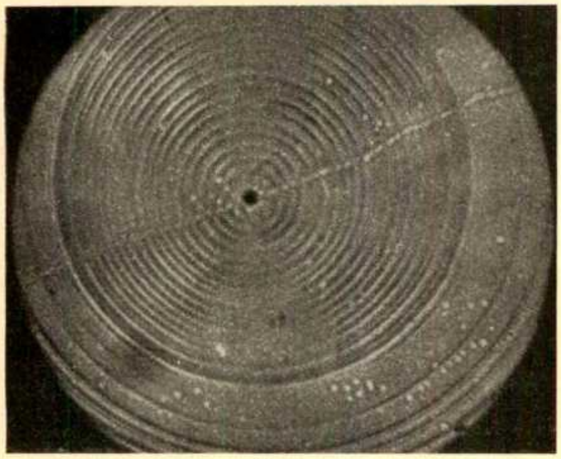

Fig. 1

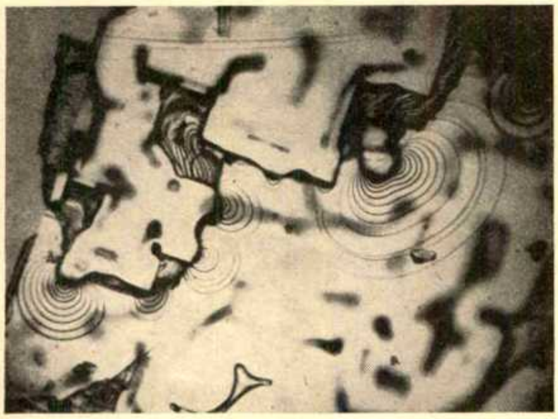

Fig. 2

especially on the edge of the surface where the two sodium chloride plates lay on each other during the evaporation.

Exo-electron Emission and the Optical Properties of Oxide-coated Metal Surfaces

EVIDENCE suggests that exo-electron emission from ionic crystals is associated with colour centres and kindred imperfections which result in energy-levels in the forbidden band of the crystal[1]. Grunberg and Wright[2] found very strong exo-electron emission from abraded aluminium, zinc and magnesium irradiated with light at 4700 Å. The tendency of these elements to form metal excess oxides led Grunberg and Wright to suggest that these may be present in the oxide oxygen ion vacancies occupied by two electrons called, by analogy with the alkali halides, F'-centres. The excitation of the F'-centres by light of 4700 Å. was suggested as an important process in the mechanism of exo-electron emission from metals.

The method of preparation of metal surfaces is known to affect the experimentally determined optical constants, no doubt due to differences in structure of the surface layers. The oxide film on a mechanically polished metal surface would probably contain large numbers of the proposed F'-centres, which might be expected to increase the dielectric constant of the film in the region of 4700 Å. with a consequent alteration in the measured values of the optical constants.

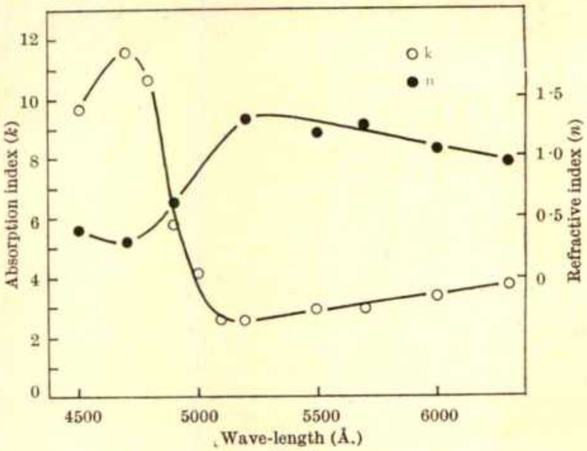

Fig. 1

The optical constants of mechanically polished aluminium and zinc have been measured for various wave-lengths in the visible region by the Drude method. Fig. 1 illustrates the variation in the absorption index, k, and the refractive index, n, for aluminium, showing a considerable increase and decrease, respectively, in the vicinity of 4700 Å. A similar result was obtained with zinc. Further work, at present in progress, is, however, required to establish a definite relationship with the proposed F'-centres.

Ratio of Nucleon Mass and Electron Mass

WITH reference to the experimental value 1840 for the ratio of nucleon and electron mass, mentioned by Prof. A. J. Rutgers in *Nature* of September 19, p. 1959, it may be noted that the ratio of proton mass and electron mass is given by the exponential equation:

$$\frac{m_p}{m_e} = \frac{1}{2}\exp(-1) \times 10^4 = 1839 \cdot 39$$

More generally, the rest mass of an elementary particle, relative to the rest mass of the electron, is $m/m_e = k\exp(-x)$, and since $\exp(-x)$ is a 'die-away factor', this formula represents the tendency of the mass of an elementary particle to decrease. For all elementary particles except the electron with minimum rest mass, and the proton with relative rest mass $m_p/m_e = k\exp(-1)$, the tendency to decrease of rest mass has been demonstrated experimentally.

Observation of Dislocations in Non-metallic Layer Structures

TRANSMISSION electron microscopy of thin foils, as developed by Hirsch, Whelan and co-workers[1], has become an important tool in studying the static[1,2] and kinetic[3] behaviour of dislocations in metals. Very few observations on non-metals have been published as yet. We have applied this technique to a number of non-metallic layer structures. One has then the advantage that very thin cleavage flakes can easily be prepared and, moreover, that the main glide plane usually coincides with the cleavage plane. In such cases extensive dislocation patterns will appear in the plane of observation. In particular, we have studied in some detail the following substances : bismuth telluride and antimony telluride, graphite, muscovite and talc. A few examples of patterns observed are reproduced in Figs. 1–3.

The c-plane of Bi_2Te_3 and Sb_2Te_3 is a glide plane and cleavage plane at the same time. Extensive hexagonal grids can be observed in both substances ; Fig. 1 gives an example observed in Bi_2Te_3 ; very similar patterns are observed in Sb_2Te_3. For both substances a dissociation into partials is to be expected since glide occurs between close-packed planes. However, in both substances the basal dislocations generally appear undissociated with the resolving power available with the standard Philips microscope. In Bi_2Te_3, there is an indication that they may be dissociated over a small distance. Extensive movement of dislocations in the c-plane, and in pyramidal glide planes, giving rise either to elimination of dislocations or to the formation of networks, has been observed. The driving force for this process is heating of the foil by the electron beam, and the resulting temperature gradients. Hexagonal networks were also found in the basal plane of muscovite. It was found that heating with the electron beam gave rise to the 'precipitation' of gases into small bubbles located on dislocations (Fig. 2).

In graphite and talc the dislocations are found to be split into partials. The phenomenon is especially striking in talc where the equilibrium separation turns out to be approximately equal to $0 \cdot 2\mu$, as can be judged from Fig. 3. This implies a very small stacking fault energy. This very low value of the stacking fault energy should be representative for a class of clay minerals ; it may explain why stacking faults occur so frequently in these substances. Fig. 3 shows dislocation ribbons and networks containing contracted and extended nodes somewhat similar to those observed in face-centred metals[2].

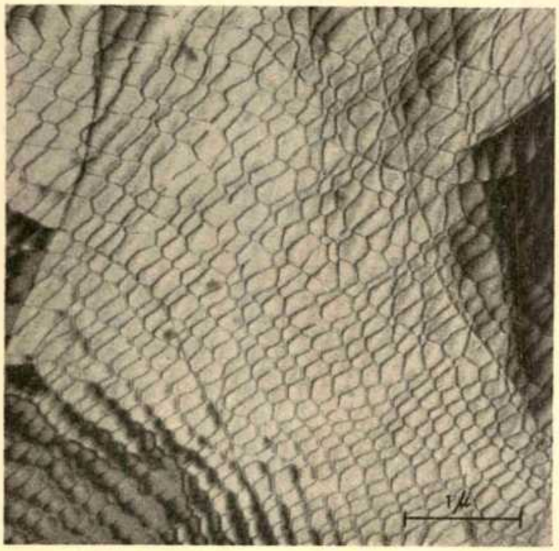

Fig. 1. Dislocation network in Bi_2Te_3. Note that certain segments of dislocations and certain node-points have left the foil

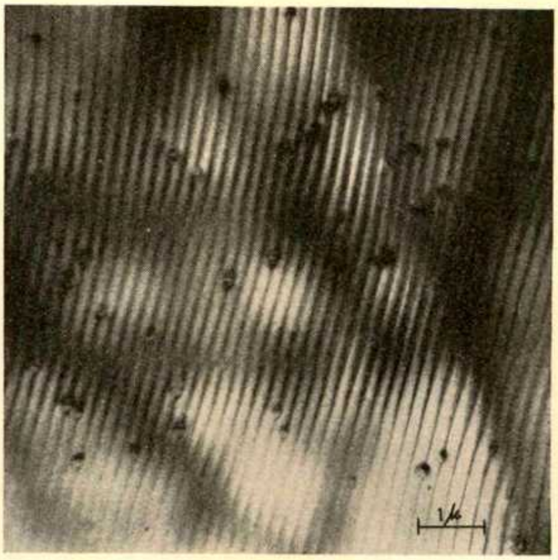

Fig. 2. Gas bubbles formed on dislocations in muscovite after irradiation with the electron beam

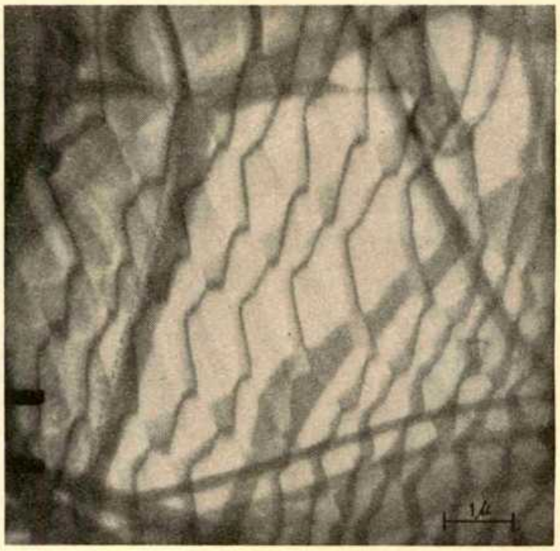

Fig. 3. Widely extended dislocations in the basal plane of talc. Note the formation of extended and contracted nodes

The dislocations in talc and in related clay minerals are of particular interest since, as a consequence of the hexagonal ring structure of the planes between which glide takes place, dislocations, split into four or six partials, are to be considered, giving rise to typical features not found in the face-centred metals.

A more detailed account of these observations will be published elsewhere.

We are indebted to Mr. J. Goens, director of the Centre d'Etude de l'Energie Nucléaire, Mol, for permission to publish this communication. We also wish to thank Mr. Nicasy for his skilful preparation of specimens and Mr. Beyens for the photographic work.

CHEMISTRY

Two New Complex Calcium Ferrite Phases

THE system CaO–FeO–Fe_2O_3 has been the subject of many investigations during the past decade, especially by Italian research workers studying the reduction of calcium ferrites and other ferrite phases of interest in cement chemistry. The phases CaO.FeO.Fe_2O_3 and CaO.3FeO.Fe_2O_3 have been identified by Burdese[1]. No ternary phases seem to have been observed in the sub-system hematite–dicalcium ferrite–magnetite. The purpose of this communication is to report the finding of two new ternary phases in this part of the system.

In a preliminary study of the systems Fe_2O_3–$CaFe_2O_4$–Fe_3O_4 and $CaFe_2O_4$–$Ca_2Fe_2O_5$–Fe_3O_4 several compositions were prepared within each triangle. Varying proportions of synthetic dicalcium ferrite, hematite and magnetite powders were mixed and small pellets were pressed. These were sealed in evacuated silica capsules, which were heated at 1,000° C. for 1–10 days and then quenched in water. The pellets were examined magnetically, microscopically, by X-rays, and analysed chemically. It soon became evident that two new ternary phases exist, located one in each of the composition triangles mentioned. The two phases appear to have the following approximate compositions: 3CaO.FeO.7Fe_2O_3 located in the Fe_2O_3–$CaFe_2O_4$–Fe_3O_4 system and 4CaO.FeO.4Fe_2O_3 in the $CaFe_2O_4$–$Ca_2Fe_2O_5$–Fe_3O_4 system. Samples having compositions close to these formulæ were non-magnetic and appeared mainly as single phases under a metallographic microscope. The stoichiometric compositions of the two new ternary phases are 24·0 per cent CaO, 7·7 per cent FeO and 68·3 per cent Fe_2O_3 for 4CaO.FeO.4Fe_2O_3 and 12·4 per cent CaO, 5·3 per cent FeO and 82·3 per cent Fe_2O_3 for 3CaO.FeO.7Fe_2O_3. Table 1 lists the *d*-spacings in Å. units and the relative intensities for the two phases as determined by a recording X-ray diffractometer.

The pattern of 3CaO.FeO.7Fe_2O_3 is strikingly similar to that reported[2,3] for calcium diferrite (CaO.2Fe_2O_3), suggesting that this ternary phase may be a solid solution between magnetite and calcium diferrite in analogy with other limited solid solutions in the system CaO–FeO–Fe_2O_3. Phase relationships and other data for the system hematite–magnetite–dicalcium ferrite will be reported when the current study of the oxygen potential for this system has been completed.

Effect of High-Energy Radiation on Mixtures of Vinyl or Related Polymers with Unsaturated Compounds

A MECHANISM has been recently proposed[1] to account for the behaviour of polypropylene on irradiation, in which the formation of a cross-link between molecules involves reaction between an activated centre in the polymer and a chain fragment containing a vinylidene double bond. This suggests that the cross-linking induced by radiation would be enhanced by the incorporation of unsaturated additives into this polymer. Considerable enhancement of cross-linking has been claimed to occur in the irradiation of 'solid solutions' of polyvinyl chloride in di- and tri-allyl esters[2].

Consideration of the above prompted an investigation into the effect of unsaturated compounds on addition polymers in general and on polymers of the vinyl family in particular. Compounds chosen to represent three classes of unsaturation were diethyl maleate, dibutyl itaconate and triallyl cyanurate. To ensure that any enhancement would be detected, it was desirable to incorporate into the polymers as much additive as possible. However, for ease of interpretation, the concentration should lie within the range in which any reaction with the polymers could be regarded as the result of an indirect effect of the radiation on the additive. An additive concentration of 10 per cent was chosen as a reasonable compromise.

The preliminary results of this survey are presented in Table 1, the criterion for enhancement of cross-linking being the variation of sol fraction with dose for the polymer plus additive when compared with that of the polymer alone (in this table 'No' indicates

Table 1

Polymethyl methacrylate	No	No	Good

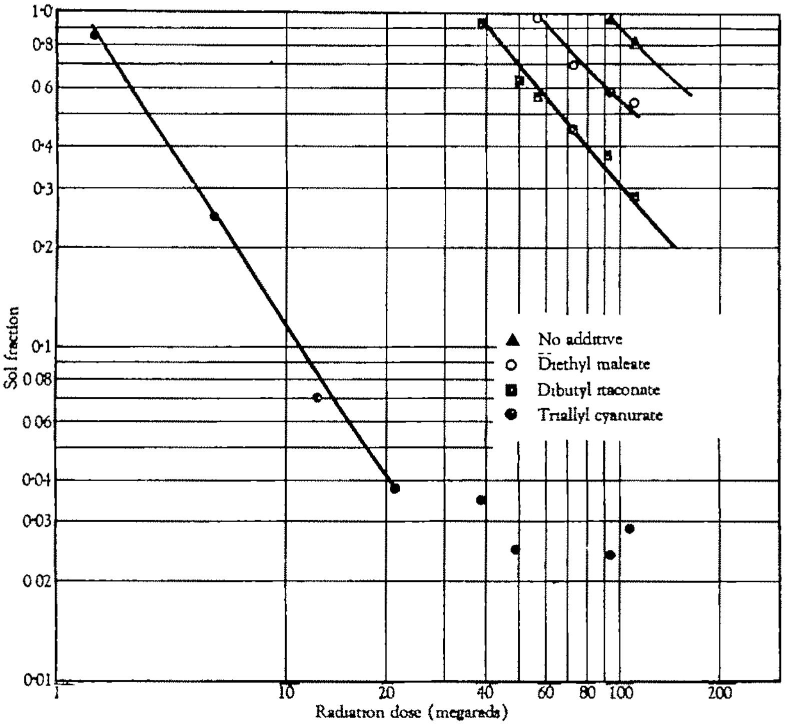

Fig. 1. Effect of unsaturated additives on polyvinyl acetate

that no gel fractions were obtained with or without the additive up to the highest dose used).

The superiority of triallyl cyanurate in enhancing cross-linking is believed to be due mainly to the presence of three unsaturated groups in the molecule. The much greater efficiency of triallyl esters compared with diallyl esters in polyvinyl chloride has already been noted[2].

Typical examples of the effect of these additives are shown in Figs. 1 and 2.

Fig. 1 shows the variation of sol fraction with dose for polyvinyl acetate alone and when mixed with the unsaturated compounds. The curves through the experimental values are drawn for degradation to cross-linking (β/α) ratios of 0·4 (polymer alone), 0·4 (polymer plus diethyl maleate), 0·2 (polymer plus dibutyl itaconate) and 0·0 (polymer plus triallyl cyanurate).

Fig. 2 similarly shows the variation of sol fraction with dose for polymethyl acrylate alone and when mixed with the additives. The curves are drawn for β/α ratios of 0·2 (polymer alone or mixed with diethyl maleate or dibutyl itaconate) and 0·0 (polymer plus triallyl cyanurate). While it is found that the addition of triallyl cyanurate to a polymer frequently gives a β/α ratio of 0·0 on irradiation, the other additives affected this ratio to a much smaller extent.

Poly*iso*butylene and polymethyl methacrylate are examples of polymers which have only a negligible tendency to develop cross-links under ionizing radiation. However, while mixtures of poly*iso*butylene with the additives became degraded, polymethyl methacrylate containing triallyl cyanurate gelled readily. This comparison suggests that the cross-linking of polymethyl methacrylate by triallyl cyanurate occurs through the ester groups. Comparison of energy yields for gas evolution and main-chain scission in polymethyl methacrylate indicates that each scission is accompanied by the decomposition of approximately one side-chain[3]. If it is assumed that addition of triallyl cyanurate results in each side-chain decomposition becoming converted to one cross-link, then the variation of sol fraction with dose would be expected to correspond with a β/α ratio of about 1. In fact, the variation of sol fraction with dose corresponds to β/α less than 0·4, so that it appears that the additive can interfere directly with main-chain scission unless, as has been tentatively suggested[3], main-chain scission arises as a direct result of side-chain scission in this polymer.

The results obtained with polypropylene are of interest in that the enhancement of cross-linking decreased with increase of the time between preparation of the sample and its irradiation. This may be due to the insolubility of the additive which immediately after compounding is present as a dispersion in the polymer, but on standing, diffuses to the surface, thus reducing the bulk concentration.

The frequent correspondence of the sol fraction–dose curves with the theoretical curves for a particular value of the β/α ratio suggests that graft polymerization of the additive is not the correct explanation of this enhancement of cross-linking. This conclusion is supported by the fact that one of the additives, diethyl maleate, has a marked reluctance to homo-

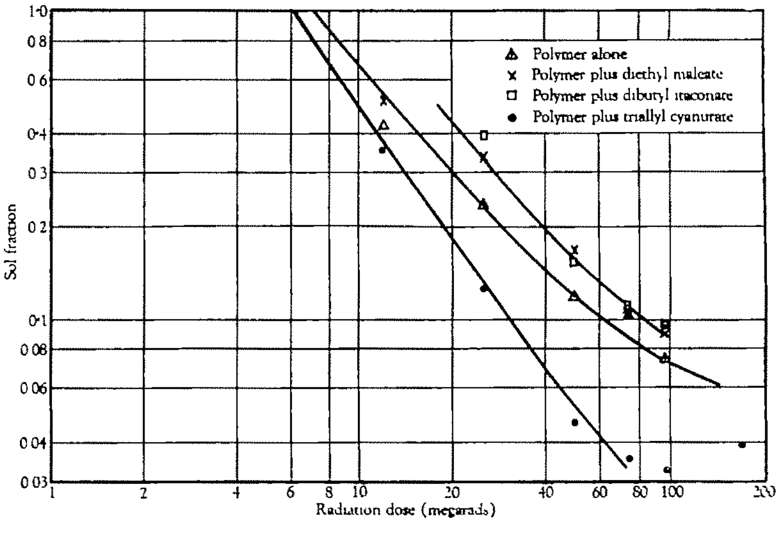

Fig. 2. Effect of unsaturated additives on polymethyl acrylate

polymerize and by the low rate at which such a polymerization would occur with the other additives at the concentration used and in such viscous media.

The additives, particularly triallyl cyanurate, seem to operate either by inhibiting chain scission in these polymers or by converting chain scission into a cross-linking reaction. It is possible that these additives may react with all the primary products of the action of ionizing radiation on the polymer. Examination of the effect of hydrolysis on the gel fraction of triallyl cyanurate cross-linked polymers may indicate the nature and extent of the interaction.

It is hoped to report the results of this investigation more fully at a later stage.

My thanks are due to Dr. R. M. Black for his advice and encouragement and to Dr. L. G. Brazier, director of research, British Insulated Callender's Cables, Ltd., for permission to publish this communication.

Second Explosion Limit of Dried Carbon Monoxide – Oxygen Mixtures

The position of the second explosion limit of carefully dried mixtures of carbon monoxide and oxygen in quartz vessels has been determined. Both the heating and withdrawal methods were used in a static system. Carbon monoxide was prepared from sodium formate and concentrated sulphuric acid, and oxygen by heating potassium permanganate. After being passed through chemical desiccants and then through cold traps, the gases underwent a final drying operation immediately before use. This final drying consisted in allowing the gases (sometimes premixed) to stand in 'Pyrex' drying vessels surrounded by liquid oxygen for at least 12 hr.

Explosion limits for carbon monoxide – oxygen (1 : 2) mixtures in the pressure-range 40–250 mm. mercury lay between the temperatures 750° and 840° C., and are shown in Fig. 1 together with the published results of other workers. It will be seen that the present results lie at considerably higher temperatures than so far reported. Experiments were also made using gas mixtures which had not undergone the *final* drying procedure mentioned above. The limits were found to lie at a temperature some 100° C. lower. Gordon and Knipe[1] have shown that small traces of water vapour lower considerably the limit temperature. We suggest, therefore, that the higher limits reported here can be attributed to the use of drier gases than those employed in earlier work.

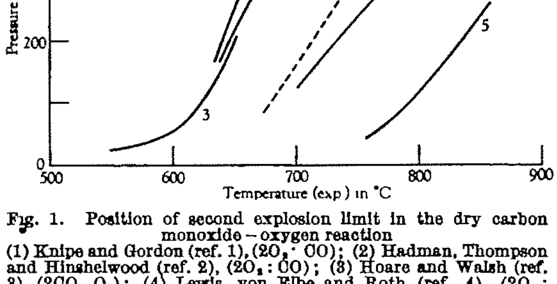

Fig. 1. Position of second explosion limit in the dry carbon monoxide – oxygen reaction

New Approach to the Synthesis of O-Phosphoserine and Related Peptides

A general method of synthesizing phosphorylated amino-hydroxy acids and derived peptides, using diphenylphosphorylchloridate as the phosphorylating agent, was introduced by Riley *et al.*[1]. This method has been applied with rather satisfactory results in the synthesis of α-carbethoxy-L-lysyl-L-(O-phosphoryl)-serylglycine[2]; but further studies on the inhibitory spectrum of phosphoserine[3] towards proteolytic enzymes, and the effect of phosphatases[3] upon various substrates as well, stress the necessity of alternate synthetic methods.

When diphenyl groups from O-diphenylphosphoryl peptide derivatives containing other than aliphatic side-chain amino-acids are removed by catalytic hydrogenation in the presence of platinum catalyst, the likelihood of reduction of the side-chain rings is apparent. In this connexion it is of interest to note that O-diphenylphosphoryl esters have been believed up to the present to resist hydrogenolysis in the presence of palladium catalyst. Based on this assumption, a stepwise removal of protecting groups from carbobenzoxy-D,L-(O-diphenylphosphoryl)serine benzyl ester has been recently reported[4]. This consists, first, in the removal of the carbobenzoxy and benzyl groups by hydrolysis in the presence of palladium and then of the phenyl groups using platinum catalyst. Thus, the intermediate product D,L-(O-diphenylphosphoryl)serine[4] was described as a crystalline compound with melting point 129–130°.

Our experience, however, with hydrogenolysis of O-diphenylphosphoryl serine peptide derivatives in the presence of palladium has led us to a different conclusion. Special emphasis has been placed so far on the hydrolysis of carbobenzoxy-D,L-(O-diphenylphosphoryl)serine benzyl ester. When the latter was hydrogenated in the presence of a palladium catalyst and two equivalents of hydrogen were absorbed in about 1 hr., we were unable to isolate the reported product O-diphenylphosphoryl serine[4].

Surprisingly enough, the oily product obtained, which is soluble in water, was proved by paper chromatography to be a mixture of at least three components. The major product consisted of monophenylphosphorylserine[5], while two other unknown compounds were travelling with entirely different R_F value than that reported[4] for O-diphenylphosphorylserine.

Though the elucidation of this finding is still in progress, it is tempting to speculate that the emergence of the carboxyl- or amino-group of serine during the hydrolysis influences the elimination of a phenyl group via the formation of an intermediate six- or five-membered ring.

Unexpected difficulties were encountered also when diphenylphosphoryl chloridate was used to phosphorylate α-carbethoxy-(ε-carbobenzoxy)-L-lysylglycyl-L-serine benzyl ester. The latter peptide derivative was synthesized as follows: Tritylglycine[6] was coupled with serine benzyl ester by the carbodiimide method, and the thick oily product thus obtained was further detritylated to give glycyl-L-serine benzyl ester hydrochloride (I) in 75 per cent yield, melting point 173–175° (decomp., softens at 165–166°). Analysis: calc., $C_{12}H_{17}N_2O_4Cl$, N 9 70, Cl 12·28; found, N 9·50, Cl 11·90.

Compound I was coupled with α-carbethoxy-(ε-carbobenzoxy)-L-lysine[2] as previously described. In our experience and in spite of a previous statement[7], coupling in anhydrous solution leads to a considerable extent to the formation of the O-peptide isomer, which is difficult to remove.

The tripeptide derivative obtained, α-carbethoxy-(ε-carbobenzoxy)-L-lysylglycyl-L-serine benzyl ester (II), melted at 141–142° (sharp), yield 40–45 per cent, $[\alpha]^{23}_{D}$ 7·4 (c. 0·54 in glacial acetic acid). Analysis: calc., $C_{29}H_{38}N_4O_9$, C 59·36, H 6·52, N 9·7; found, C 59 45, H 6·72, N 9·53.

Compound II was phosphorylated with diphenylphosphorylchloridate in a similar manner to that described for its analogue, α-carbethoxy-(ε-carbobenzoxy)-L-lysyl-L-serylglycine benzyl ester[3]. Several attempts to obtain the product in a solid form have failed, probably owing to the presence of unphosphorylated peptide derivative which is difficult to separate by fractional precipitations. When a larger excess of chloride was used the result turned out to be less satisfactory. The oily product obtained, when hydrogenated and studied by paper chromatography, was found to give a mixture of several ninhydrin-positive spots. The possibility of some splitting of peptide bonds was naturally borne in mind[8].

In the course of our studies for improved methods for the synthesis of O-phosphorylated peptides, we have employed di-p-nitrobenzylphosphorylchloridate[9] as the phosphorylating agent.

Since benzyl groups are split off by catalytic hydrogenation with palladium catalyst, this method may be of wider application than that employing diphenylphosphorylchloridate.

Moreover, di-p-nitrobenzylphosphorylchloridate was expected to give readily crystallizing products as in the case of N-phosphoryl amino-acids and peptides[10]. Indeed, we have succeeded in preparing carbobenzoxy-D,L-(O-di-p-nitrobenzylphosphoro)-serine benzyl ester in crystalline form in 50–60 per cent yield. The product was melted at 107–108°, while the corresponding diphenylphosphoryl derivative has a considerably lower melting point (49–50°) and is difficult to crystallize. Analysis: calc., $C_{32}H_{30}N_3O_{12}P$, N 6·1, P 4·57; found, N 6·2, P 4·85.

Tetra-p-nitrobenzylpyrophosphate, readily prepared from di-p-nitrobenzylphosphate and carbodiimide in dimethylformamide, constitutes another route under investigation. So far we have succeeded in phosphorylating α-amino groups in the presence of tertiary base. Thus, N-di-p-nitrobenzylphosphoroglycine benzyl ester was prepared in about 50 per cent yield, melting point 111–112°. Analysis: calc., $C_{23}H_{22}N_3O_9P$; N 8·15, P 6·09; found, N 8·05, P 6·32.

The potentialities of di-p-nitrobenzylphosphorylchloridate and tetra-p-nitrobenzylpyrophosphate for the synthesis of O-phosphorylated peptides will be discussed elsewhere.

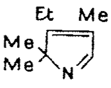
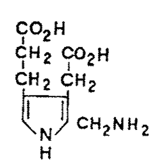
Formation of I- and III-Type Porphyrins by the Polymerization of Pyrroles

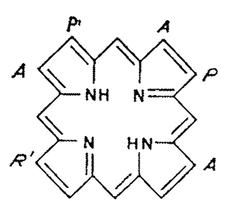
IN a recent paper[1] we discussed the alkylation of tri- and tetra-alkylpyrroles and referred to the 2 : 3 : 4-trialkylpyrroles which on alkylation could give either 2 : 3 : 4 : 5-tetra-alkylpyrroles or 2 : 2 : 3 : 4-tetra-alkyl-2(H)pyrroles (for example, I). The factors which decided the course of this reaction were delicately balanced, for whereas the methylation of the Grignard derivative of 2 : 3 : 4-trimethylpyrrole gave 2 : 3 : 4 : 5-tetramethylpyrrole almost exclusively, a similar methylation of 2 : 4-dimethyl-3-ethylpyrrole (cryptopyrrole) gave 3-ethyl-2 : 2 : 4-trimethyl-2(H)pyrrole (I) as the major product.



(I)



(II)

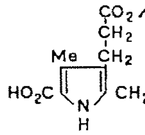


(III)

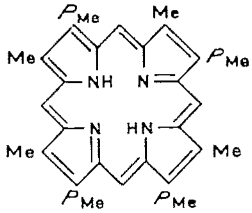
$A = \cdot CH_2CO_2H$
$P = \cdot CH_2CH_2 \cdot CO_2H$

This duality of reaction path has some interesting consequences, in particular in considering the biogenesis of natural porphyrins which are derived by the polymerization of porphobilinogen (II). Most of the common porphyrins belong to the so-called III series, for example, uroporphyrin III (III; $R = P$, $R' = A$). Although members of the I series, for example uroporphyrin I (III; $R = A$, $R' = P$), are also natural products, the II and IV series apparently do not occur naturally. In considering the mechanism by which the I- and more especially the III-type porphyrins might be formed from porphobilinogen it is clear that the initial reaction is the electrophilic alkylation of one molecule of porphobilinogen, a 2 : 3 : 4-trialkylpyrrole, by another porphobilinogen molecule. We have suggested[2] that, if this occurs at the 5-position, as in the methylation of 2 : 3 : 4-trimethylpyrrole, in a repeating process then uroporphyrin I will be the eventual product; if reaction occurs at the 2-position as in the methylation of cryptopyrrole, then uroporphyrin III results after a series of specified migrations. It was therefore of interest to ascertain how far this type of polymerization could be controlled to give porphyrins of the I or III series. Such reactions have considerable biochemical as well as chemical interest as certain porphyrias are known to be associated with the biological production of I- rather than III-type porphyrins. Cookson and Rimington[3] examined the polymerization of porphobilinogen under various conditions *in vitro* and found that, at 100°, uroporphyrin III was obtained rapidly and in high yield with no trace of the series I isomer. At 20°, the polymerization took several days and was dependent on pH; at pH 6·5, only the series III isomer was formed, but at pH > 10, equal amounts of the series I and III isomers were obtained. These results have been confirmed by Mauzerall and Granick[4].

We have now shown that these observations can be extended to the coproporphyrin series. Thus whereas the acid-catalysed polymerization of the pyrrole (IV; R = Me) had been shown[5] to yield coproporphyrin III tetramethyl ester (V), m.p. 151–154°, as the sole recognizable product, it has now been found that if the polymerization is effected by hot ethanolic ammonia, the product is mainly coproporphyrin I tetramethyl ester, m.p. 237–240°, containing some of the series III isomer.



(IV)

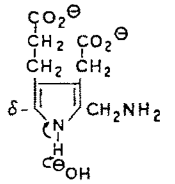


(V)

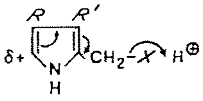
(P_{Me} = ·CH₂ CH₂·CO₂Me)

Likewise, polymerization of the corresponding dicarboxylic acid (IV; R = H) in ethylene glycol solution in presence of sodium carbonate, gave a product which, after esterification by methanolic hydrogen chloride, could be resolved by chromatography into fractions which were mainly coproporphyrin I tetramethyl ester on one hand and mainly the series III isomer on the other. These identifications were made on the basis of melting points of the methyl esters and chromatographic examination of the free porphyrins in the system 2 : 6-lutidine–water, and we are very grateful to Prof. C. Rimington and Mrs. A. Latter, who carried out these determinations.

The course of these *in vitro* polymerizations is therefore controlled by pH, a high pH leading to the formation of a mixture of I- and III-type porphyrins and a low pH leading only to the III-type. From the mechanistic point of view, the alkaline polymerization is regarded as involving a loosening of the pyrrole N–H bond by the alkali, leading to an increased electron density in the pyrrole ring (as in VI). This enhances the ease of electrophilic substitution at the vacant 5-position and leads eventually to I-type porphyrins. Ionization of the side-chain carboxyl groups in porphobilinogen will doubtless accentuate this effect, but the parallel results with the pyrrole esters (for example, IV) show that the free acid groups are not essential.



(VI)



(VII)

In acidic media, a pyrrole of type (VII) will tend to ionize in the manner shown (X = OAc, Br or $\overset{+}{\mathrm{N}}\mathrm{H}_3$ in the protonated form of porphobilinogen), which causes a deactivation of the ring towards electrophilic attack of the 5-position and thus favours reaction at position 2-. This substitution pattern leads to the formation of III-type porphyrins. It is not yet clear how far these ideas can be extended to the *in vivo* polymerizations of porphobilinogen to uroporphyrins I and III, but it would appear probable that certain aspects of the reaction mechanisms are common to both *in vivo* and *in vitro* porphyrin syntheses. These views were communicated to Prof. A. Neuberger, who included them in his Section Lecture to the Seventeenth International Congress of Pure and Applied Chemistry at Munich, 1959.

In recent papers, Bogorad[7] describes the isolation of an enzyme, porphobilinogen deaminase, which causes the polymerization of porphobilinogen to uroporphyrinogen I (cf. alkaline catalysis), but in the presence of a second enzyme, uroporphyrinogen isomerase, the product was uroporphyrinogen III (cf. acid catalysis). It is possible that some chemical interaction occurs between the two enzymes which causes a modification of the essential functional groupings, and it may not be necessary to postulate, as Bogorad does, a substrate other then porphobilinogen for the isomerase.

In order to meet Bogorad's suggestions, Wittenberg has recently[8] published a mechanism for porphobilinogen polymerization which involves an octapyrrolic intermediate with successive dehydrogenation and hydrogenation steps. Apart from the improbability that a 24-membered macrocylic ring would be formed in such a facile reaction, the theory does not offer a convincing explanation of the exclusive production of III-type porphyrins under conditions involving acid catalysis. Moreover, it postulates for the formation of the tripyrromethane portions of the large macrocycle a type of condensation which has not been observed in the laboratory.

Wittenberg also refers to the problem of the biogenesis of vitamin B_{12} which, like the porphyrins, has porphobilinogen as a pyrrolic intermediate. He makes the point that if the formation of the linkage between rings A and D is the initial step in the polymerization, as we suggest, this does not accord with the view we have previously advanced[9], that the final ring closure in the formation of vitamin B_{12} is the formation of the direct link between rings A and D. These apparently contradictory views can be reconciled if an additional rearrangement of uroporphyrinogen III is involved. The nature of this reaction is unknown but a pinacol rearrangement of the type visualized by Woodward[10] to explain the exocyclic C_1 substituent in magnamycin is a possibility and is being examined in our laboratory.

BIOCHEMISTRY

Free Amino-acids of Some Fungi

THE nature and amounts of free amino-acids in higher plants are becoming relatively well known since the advent of paper chromatography. However, few investigations of amino-acids in the Cryptogams have been made. Fowden[1] has studied the amino-acids of certain algae, Mansford and Raper[2] those of *Mucor mucedo*, Fluck and Richle[3] those of *Fusarium lycopersici*. The yeasts, *Aspergillus*, *Penicillium* and *Neurospora* species[4], have been extensively studied but the rest of the fungi remain largely unexamined.

Robbins[5] has classified fungi physiologically according to their ability to utilize various forms of nitrogen: Group I, Molecular nitrogen, NO_3^-, NH_4^+ and organic nitrogen; Group II, NO_3^-, NH_4^+ and organic nitrogen; Group III, NH_4^+ and organic nitrogen; Group IV, organic nitrogen.

It appeared desirable to study the free amino-acids of a taxonomic range of fungi which included most of these physiological groups. The species chosen were as follows: Phycomycetes—*Pythium ultimum* Trow. (Group II); *Phytophthora cactorum* Leb. and Cohn (Schroet.) (Group IV); *Phycomyces nitens* + (Agardh) Kunze and Schmidt (Group IV); *Thamnidium elegans* Link (Group III). Ascomycetes and Fungi Imperfecti—*Chromocrea spinulosa* (Fuckel) Petch (Group II); *Fusarium culmorum* (W.G.Sm.) Sacc. (Group II); *Fusarium javanicum* Koorders (Group II). Basidiomycetes—*Stereum purpureum* Pers. ex Fries (Group II).

Pythium ultimum was cultured on liquid Czapek–Dox medium with nitrate as the nitrogen source and sucrose as the carbon source. The others were grown on a liquid medium in which asparagine (0·3 per cent) was the nitrogen source and glucose (2 per cent) the carbon source. Minerals and vitamins included potassium dihydrogen phosphate (0·1 per cent), magnesium sulphate and potassium chloride (0·05 per cent) and trace amounts of Ca^{++}, Fe^{++}, Zn^{++}, Cu^{++}, Mn^{++}, MoO_4^- and thiamine. All fungi were grown at 25° C. as stationary cultures in 250 ml. Erlenmeyer flasks containing 100 ml. liquid medium.

After varying intervals of time depending on the species growth-rate, fully developed mycelial pads still in growth were separated from the medium and were washed once with distilled water. The amino-acids were then extracted by blending the hyphæ with 87 per cent alcohol at room temperature. The extracts were concentrated and then examined for amino-acids by paper chromatography.

A summary of the free amino-acids found in the fungal hyphæ is presented in Table 1.

Several amino-acids were found in all the fungi studied. Fowden[1] found a similar pattern in three species of algae. The amino-acid, γ-amino butyric, has been found in a wide range of plants and it is interesting to record its presence in seven of the eight fungi examined. It is not a constituent of protein hydrolysates, nor is β-alanine, which was found in four of the fungi. Large amounts of proline

Incubation time (days)	10	29	16	26	14	14	24	19

+ + +, Strong ninhydrin colour, + +, moderate colour +, weak colour; —, not detected.

were found in *Phytophthora cactorum* and its presence was noted in *Thamnidium elegans*. Tyrosine was present in small amount in several, but tryptophan was not detected in any of the fungi. Glutamine appeared to be present in larger amounts than asparagine. Four unidentified compounds were found in some of the fungi. These corresponded on chromatograms to the positions of α-amino adipic acid, 3 : 4-dihydroxyphenylalanine, ethanolamine and taurine, but identification must await further work.

Under these experimental conditions, there do not appear to be any substantial differences between fungi belonging to different taxonomic and physiological groups. The number and relative amounts of free amino-acids present in fungi show an overall similarity to those in higher plants.

The assistance of Dr. E. G. Bollard is gratefully acknowledged.

Specificity *in vitro* of a Phenoloxidase System from *Periplaneta americana* (L.)

ENZYMES capable of oxidizing mono- and diphenols are widely distributed in insects; some of these compounds are involved in the biosynthesis of exoskeletal substances, notably sclerotin[1]. While several *ortho*- and *para*-diphenols have been extracted from cuticle, relatively little is known about the corresponding synthetic enzymes. Recent work in connexion with the reaction of phenolic derivatives with proteins ('tanning reaction') has been reviewed by Hackman[2], Mason[3] and Dennell[4]. The present results form part of an investigation of the intermediary metabolism of phenolic substrates involved in sclerotin formation in *Periplaneta*.

It has been already shown that the sclerotin walls of the egg capsule (ootheca) are formed by the intermingling of the secretions of the left and right colleterial glands[1]. As a result of this, protocatechuic acid[5] (3 : 4-dihydroxybenzoic acid) is liberated from its 4-O-β-D-glucoside (secreted by the left gland) by the action of a β-glucosidase (from the right gland)[6]. Some evidence[1] suggests that the protocatechuic acid is oxidized enzymically by a secretion of the left gland[7], afterwards to link with structural proteins to form sclerotin.

It has now been confirmed that the oxidative enzymes are present in the lumen of the left gland and are released in the form of a highly turbid suspension when the dissected left gland is allowed to stand for a few minutes in distilled water. The preparation can be freed from cellular debris by centrifugation at 0° C. and from endogenous substrates by dialysis ('Cellophane') against 0·01 *M* sodium chloride. Subsequent salt precipitation gave fractions of very high enzymic activity between 0·1 *M* and 0·2 *M* sodium chloride (final concentration).

The activity of the dialysed enzyme preparations was investigated in 0·1 *M* sodium phosphate buffer (*p*H 6·8) with a variety of phenolic compounds (each in a final concentration of 0·002 *M*) using Warburg manometers (5–6 ml.) at 37° in an atmosphere of oxygen. The results are shown in Table 1.

Table 1. SUBSTRATES FOR THE PHENOLOXIDASE SYSTEM FROM LEFT COLLETERIAL GLANDS OF *Periplaneta*

Active	Inactive
Protocatechuic acid	DL-3 4-Dihydroxyphenylalanine
3 : 4-Dihydroxybenzoic acid	L-Tyrosine (*para*)
3 : 4-Dihydroxypropionic acid	L-Tyrosine (*ortho*)
3 : 4-Dihydroxybenzaldehyde	*p*-Hydroxybenzoic acid
Catechol	DL-3 : 4-Dihydroxyphenylethylamine (dopamine)
Hydroquinone	Resorcinol
p-Phenylenediamine	

The enzyme promoted rapid oxidation of a number of *o*- and *p*-diphenols with the notable exception of 3 : 4-dihydroxyphenylalanine and the corresponding amine. L-Tyrosine (either *ortho* or *para*) or other monophenols were not oxidized.

Thus, in the sense of Keilin and Mann[8] and Dawson and Tarpley[9], this enzyme can be regarded as a laccase and in no sense a tyrosinase.

The enzyme activity is abolished by being heated above 70° and by 0·002 *M* potassium cyanide. It is unaffected by 4-chlororesorcinol and diethyldithiocarbamate. Preliminary investigations indicate that the enzyme is a protein–copper complex.

It is emphasized that the enzyme preparation has not yet been obtained in a soluble form but that it occurs in the gland in a finely divided state exhibiting a strong Tyndall effect. This is supported by electron microscopy[10].

It has not yet been found possible to separate the enzyme from the protein-precursor of sclerotin, of which indeed the enzyme may be a part.

Infra-red Spectra of Capsular Polysaccharides from Thirteen Strains of *Cryptococcus neoformans*

STUDIES of infra-red absorption spectra of immunopolysaccharides have received little attention until recently. Thus, Levine, Stevenson and Kabler[1] were able to show that the serologically reactive and type specific pneumococcal polysaccharides have distinctive spectra by which they can be identified. Later, Watson, Marinetti and Scherp[2] working with the specific hapten of group *C* meningococcus were successful in assigning a provisional structure for the hapten by the aid of infra-red spectral analysis. Inasmuch as purified cryptococcal polysaccharides have shown serological reactivity by precipitation

with specific hyperimmune rabbit serum[3,4] in addition to stimulating antibody formation in mice[5], it was deemed desirable to investigate their infra-red spectra and to compare these with the spectra of crude preparations.

Samples of the polysaccharides from pathogenic *Cryptococcus neoformans* strains were purified by the methods of Gadebusch[5], triturated in repurified commercial paraffin oil ('Nujol'), and spectra obtained from a paste thickness of approximately 0·01 mm. by means of a Perkin–Elmer double-beam recording spectrophotometer. In all cases the thinnest film possible was employed to bring out detail between 8·5 and 15μ. Crude polysaccharides were so designated because they had not been specifically deproteinized by the methods of Sevag[6].

In spite of the diverse origin of the cryptococcal polysaccharides (Table 1), the spectra were so strikingly similar that identification seems extremely difficult, if not impossible. Purification of these substances, while producing definite immunological differences[5], did not alter their infra-red spectra beyond a somewhat greater resolution of existing peaks. These spectral relationships have been borne out by analytical data which have shown similar values for carbon, hydrogen, oxygen, reducing sugar, uronic acid and acetyl groups (unpublished work). All these polysaccharides contain negligible amounts of nitrogen and phosphorus.

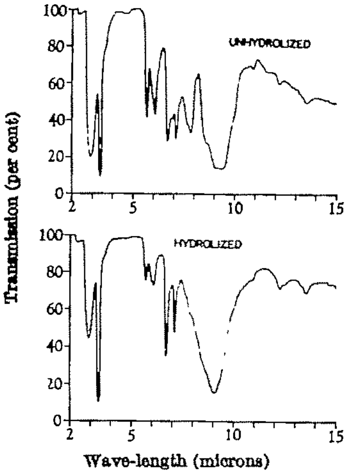

Fig. 1. Infra-red spectra of hydrolysed and unhydrolysed purified polysaccharide from *C. neoformans* strain *BRI*

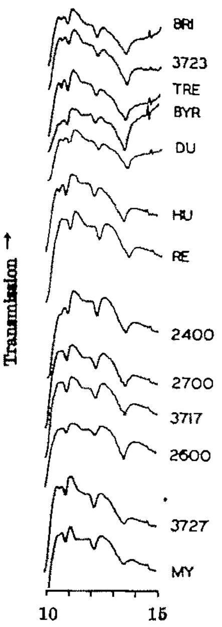

Fig. 2. Infra-red spectra of *C. neoformans* polysaccharides. The upper six spectra were from purified samples and the remainder were from crude preparations

As a result, it seems quite unlikely that capsular type identification as performed serologically by Evans[7] could be accomplished by a study of the infra-red spectra of their polysaccharides. In this respect at least spectral investigations of pneumococcal polysaccharides have been more encouraging[8].

Despite partial interference by 'Nujol' absorption (3·43μ, 6·85μ, 7·27μ), a few preliminary remarks may be made regarding the infra-red spectra of *C. neoformans* polysaccharides: (1) The source for the moderately strong carbonyl band at 5·77μ is probably the ester linkage and more specifically O-acetyl. Acids absorbing at this wave-length have been eliminated as a source, since precipitation was not carried out at low *p*H. In addition, the presence of the frequently accompanying 8·0–8·2μ band lends further confirmation to the ester origin. (2) Bands at 6·20 and 7·10μ are characteristic of the carboxylate ion which in turn may be derived from uronic acids. Since these polysaccharides all contain a uronate moiety, the bands at 6·24 and 7·07μ may well have been displaced somewhat. (3) Although bands at 6·85 and 7·27μ are partially attributable to 'Nujol' absorption, the intensity of absorption indicates the presence of another structural component, probably the —CH_3 group. (4) Carefully controlled hydrolysis of a water solution of *C. neoformans* strain *BRI* purified polysaccharide in the presence of sodium hydroxide produced a substantial diminution in the absorption spectra at 5·77, 6·24, 7·07, and 7·27μ (Fig. 1). The band at 8·0–8·2μ now appears only as a shoulder on the larger, broader band between 9 and 10μ. These changes have been interpreted as a combination of ester and uronate hydrolysis. The moderate decrease in absorption of the 7·27μ band indicates partial loss of this terminal —CH_3 group. (5) Finally, in the region above 8·5μ, the bands at 11·15, 12·50 and 13·85μ (Fig. 2) appear to be characteristic for both crude and purified cryptococcal polysaccharides.

Carnitine in Lipid Metabolism

THE finding by Fraenkel and Friedman[1] that carnitine (4-trimethyl amino 3 hydroxy butyric acid) is an essential growth factor for certain organisms (vitamin B_T) and its availability by synthesis have renewed interest in the problem of its biochemical function.

Recent reports suggest that carnitine is implicated in lipid metabolism. Schaepdryver and Vleeschhouwer[2] showed that it increased the fat content of lymph; Fritz and McEwan[3] postulated a role in fat transport; and it has been reported present in vagotonin[4] and lipocaic[5]. Binon and Deltour[6] reported that, contrary to the belief that the nitrogenous base of dog serum phospholipid was all choline, one-third was actually carnitine.

The chemical similarity of carnitine and choline suggests that carnitine might possess anti-lipotropic activity. This possibility was examined by the 6-day mouse test of Welch and Welch[7]. Seventy young male mice were fed on (*a*) high fat, negative control diet; (*b*) positive controls containing 0·5 per cent choline; (*c*) test diet containing 0·5 per cent carnitine; and (*d*) test diet containing 1·0 per cent carnitine. The results (Table 1) show that carnitine had no effect on the fat content of the liver. This result substantiates the finding of Fritz[8] on rats.

As a further examination of the role of carnitine in lipid metabolism the finding of Binon and Deltour[6] was investigated. These authors analysed the total lipid fraction from dog serum by differential reineckate precipitation[9]. The precipitate at *p*H 10 was assumed to be choline, and that at *p*H 2, carnitine. The carnitine was not further identified.

Table 1. TOTAL LIPID CONTENT OF MOUSE LIVERS (FOUR ANIMALS GROUPED IN EACH DETERMINATION)

Group	High diet fat. Negative controls (choline + carnitine absent) (gm./100 gm.)	Plus 0 5 per cent choline. Positive controls (gm./100 gm.)	Plus 0·5 per cent carnitine (gm./100 gm.)	Plus 1·0 per cent carnitine (gm./100 gm.)
Total animals used	20	20	20	10 (2 per group)
1	54 2	10 9	58·6	58·5
2	55 4	12·4	55·0	57 2
3	52·2	19·9	55 4	47 5
4	59·0	11·2	51·8	47·1
5	60 7	22 5	53·0	62·1

The lipids from 300 ml. of foxhound serum were extracted with ethanol/ether and hydrolysed by boiling with methanolic hydrochloric acid (following the procedure of Binon and Deltour). The two fractions obtained by differential reineckate precipitation at *p*H 10 (voluminous) and *p*H 2 (trace) were examined by paper chromatography. They were run in the presence of silver nitrate[10] in ethanol/ammonium hydroxide/water (95 : 5 : 5) and in a second experiment in *iso*propanol/ammonium hydroxide/water (20 : 1 : 2). The spots were located with iodine and with potassium bismuth iodide. Choline was the only quaternary ammonium compound detected in both reineckate fractions. Direct chromatography of the phospholipid hydrolysate, without reineckate treatment, also failed to reveal the presence of carnitine.

In addition to the serum investigation the phospholipid fraction of beef muscle was examined. The fraction was obtained by petroleum ether/ethanol extraction followed by acetone precipitation[11]. The hydrolysed material showed no reineckate precipitate under acid conditions, and chromatography revealed choline as the only quaternary ammonium compound.

It thus appears that carnitine is not present in phospholipids of blood or muscle, and that it does not play a part in transmethylation reactions that lead to the formation of choline or betaine.

A detailed account of this work and further investigations into the role of carnitine will be published elsewhere.

17-Oxosteroids of Pregnant Ewes' Urine

IN view of the increasing use of steroid hormones and stilbene derivatives in agriculture and agricultural research, it was felt that it was necessary to investigate steroid excretion by the ewe.

The isolation of 5β-pregnane-3α : 20α-diol from the urine of the pregnant ewe was recently reported by Robertson and Coulson[1]. As a continuation of this work the neutral ketonic fraction of pregnant ewes' urine was investigated.

22·5 l. of urine representing twenty 24-hr. collections from two ewes in the fourth month of pregnancy, were acid hydrolysed and extracted in the usual way. The neutral extract was separated into ketonic and non-ketonic fractions by the method of Dorfman[2].

The ketonic fraction of 100 mgm. was then chromatographed on an alumina column but no crystalline fractions were obtained.

The residues from the column were bulked into four main fractions (*A–D*), and 1/100 aliquots from each of these fractions were then chromatographed on paper in each of the following systems: (1) 100–120 petroleum ether–propylene glycol, (2) Bush's system *A*, (3) toluene–propylene glycol.

A series of known steroids were also run to provide standards and the chromatograms were sprayed with a modified Zimmerman reagent to locate 17-oxosteroid-like material. These results are summarized in Table 1.

Table 1. CHROMATOGRAPHY OF THE NEUTRAL KETONIC FRACTION OF PREGNANT EWES' URINE

Fraction	Substance†	Approximate quantity present‡	R_F value* in system		
			Petroleum ether–propylene glycol	Bush *A*	Toluene–propylene glycol
		(μgm.)			
A	*A*(1)	5	0·2	0·23	0·6
	A(2)	10–20	0·58	0·83	1·0
B	*B*(1)	10	0·2	0·23	not resolved
	B(2)	10	0·58	0·83	1·0
	B(3)	5	not resolved	0·68	not resolved
C	*C*(1)	5	not resolved	not resolved	0·15
D	No 17-oxosteroids	—	—	—	—
	Androsterone		1·0	1·0	1·0
	Aetiocholanolone		0·6	0·85	1·0
	Dehydro*epi*androsterone		0·5	0·69	1·0
	$\Delta^{1,4}$ Androstadiene-3 : 17-dione		0·55	0·55	1·3
	Δ^{4} Androstene-3 : 17-dione		1·25	0·86	1·3

* The rates of flow are expressed relative to androsterone.

† Only those materials which gave purple colour reactions similar to 17-oxosteroids are recorded.

‡ The approximate quantity of material present was deduced by comparison of the spot produced with one produced by 20 μgm. of steroid, taking into account the fact that the lower limit of sensitivity of the reagent was about 2·5 μgm. of steroid per spot.

Material *A*(1) and *B*(1) were apparently the same substance but could not be identified from the standards. This material like *C*(1) was of low R_F value and was therefore of a more polar nature than the standards.

From a comparison of R_F values substances *A*(2) and *B*(2) were apparently identical with aetiocholanolone.

Substance *B*(3) which was only resolved from *B*(2) in the Bush system and was therefore of very similar R_F value to *B*(2) in the other systems was tentatively identified as dehydro*epi*androsterone.

As 1/100 aliquots were run on paper the total 17-oxosteroid content of the urine was probably of the order of 5 mgm., which correspond to an excretion-rate of 0·25 mgm. per sheep per 24 hr. This appears to be made up of 2 mgm. (100 μgm. per sheep per 24 hr.) of aetiocholanolone, 500 μgm. (25 μgm. per sheep per 24 hr.) of dehydro*epi*androsterone and 2·5 mgm. (125 μgm. per sheep per 24 hr.) of at least two other unidentified steroids.

Thus the 17-oxosteroid excretion in pregnant ewes' urine, like the pregnanediol excretion, is very small by comparison with human urinary excretion.

As a result of the small quantity of 17-oxosteroids present and the large quantities of other material encountered it was concluded that the accurate quantitative estimation of 17-oxosteroids in sheep's urine could not be carried out by the usual methods.

Isolation of 17-*Epi*œstriol from the Urine of Pregnant Women

THE isolation of 16α-hydroxyœstrone in 1957 by Marrian, Watson and Panattoni[1] led these authors to suggest that this compound might be the metabolic intermediate in the 'hydration' of œstrone to œstriol. In the same year, Brown and Marrian[2] reported that about 40 per cent of 16α-hydroxyœstrone when administered to human subjects was afterwards excreted in the urine as œstriol. Breuer, Nocke and Knuppen[3] found after incubation of 16α-hydroxyœstrone with slices of normal human liver in addition to œstriol a second metabolite which was identified as 17-*epi*œstriol (œstra-1,3,5-triene-3,16α,17α-triol). In view of these findings it seemed reasonable to assume that 17-*epi*œstriol might be a normally occurring metabolite of the œstrogens, and therefore, an attempt has been made to isolate 17-*epi*œstriol from urine during pregnancy.

Late-pregnancy urine was hydrolysed with concentrated hydrochloric acid, extracted with ether and the extract washed with an aqueous solution of sodium bicarbonate and water. The 'polar' fraction containing œstriol and its epimers was recovered by water extraction and then further purified by saponification. In order to separate the *cis*-glycols (16-*epi*œstriol and possibly 17-*epi*œstriol) from the *trans*-glycols (œstriol and 16,17-*epi*œstriol) the material was treated with anhydrous acetone containing 1 per cent hydrochloric acid. The acetonides were extracted with chloroform and hydrolysed with 0·5 *N* phosphoric acid. The fraction thus obtained was chromatographed in small portions on a large number of sheets of paper using the system formamide/chloroform. The areas corresponding to the position of 17-*epi*œstriol were eluted with methanol, the eluates combined and rechromatographed in the same system for 6 hr. After spraying the paper with Folin and Ciocalteu's reagent a blue spot was detected which had the same mobility (1·8 cm./hr.) as authentic 17-*epi*œstriol. In a second experiment, the areas expected to contain 17-*epi*œstriol were eluted, the eluates evaporated and subjected to sublimation under normal pressure. Crystals were obtained which showed the same melting point (233–235°) as authentic 17-*epi*œstriol. The material had the same absorption curve as 17-*epi*œstriol in the ultra-violet region (maximum at 279 mμ), with the Kober-reaction (maximum at 515 mμ) and with the sulphuric acid/water reaction (maxima at 286 and 456 mμ). The mobility of the fast black salt potassium derivative (0·33 cm./hr.) was identical with that of 17-*epi*œstriol when chromatographed in the system toluene/light petroleum/ethanol/water (200 : 100 : 30 : 70).

In view of the evidence presented here it is concluded that in addition to œstriol[4], 16-*epi*œstriol[5] and 16,17-*epi*œstriol[6], the fourth possible isomer, 17-*epi*œstriol, is present in human pregnancy urine.

As compared with œstriol, however, its concentration is very small. In a pooled late-pregnancy urine, the yield of 17-*epi*œstriol as determined by the Kober reaction was approx. 10 μgm./l., whereas the concentration of œstriol amounted to 15 mgm./l.

Full experimental details will be published elsewhere. I am grateful to Dr. R. Knuppen for preparing 17-*epi*œstriol, to Dr. W. Nocke for advice on the technique of the preparation and hydrolysis of 17-*epi*œstriol–acetonide and to Mrs. Brigitta Dumont and Miss Gerta Pangels for skilled technical assistance.

Labelling of Deoxyribose with Carbon-14 in Relation to Incorporation of Phosphorus-32 into the Nucleotides of Deoxyribonucleic Acid of Rat Thymus Cells

It has previously been shown[1,2] that when rat thymus cells are incubated in the presence of glucose labelled with carbon-14, the isotope is incorporated to a different extent in the ribose moieties of the four individual types of nucleotide derived from ribonucleic acid. The ribose attached to the pyrimidine bases has a specific activity lower than that of the purine-bound ribose. The present report deals with experiments on the sugar component of deoxyribonucleic acid, and also with a comparison of carbon-14-labelling of deoxyribose and incorporation of phosphorus-32 into the nucleotides of deoxyribonucleic acid.

Male albino rats weighing about 150 gm. were used. The thymus glands were removed under ether anæsthesia; a suspension of the thymus cells was prepared[3] and the cells were incubated in the presence of glucose-^{14}C (generally labelled). At the end of the incubation the acid-soluble material and lipids were extracted from the thymus cells. The residue was extracted with 10 per cent sodium chloride solution at 100° C. to isolate the sodium nucleates, which were then fractionated into ribonucleotides and deoxyribonucleic acid by alkaline hydrolysis and subsequent acidification[4]. The deoxyribonucleic acid was degraded by deoxyribonuclease and snake venom to nucleosides which were separated by paper chromatography in *n*-butanol/ammonia[5]. Each of the nucleoside fractions was degraded[6] to give free deoxyribose, which was further purified by paper chromatography using ethyl acetate/acetic acid/water as solvent[7]. Deoxyribose was determined in an aliquot of the eluate by the diphenylamine reaction[8], and another aliquot was taken for radioactive assay.

Table 1 shows the specific activity of deoxyribose derived from the four nucleosides obtained from deoxyribonucleic acid. It can be seen that the incorporation of carbon-14 into the purine-bound deoxyribose is more than twenty times greater than the incorporation into the pyrimidine deoxyribose. This finding shows a similar trend to the results obtained with ribonucleic acid[2], although the difference between the values of specific activity of the purine ribose and the pyrimidine ribose was not as great as that found here for deoxyribose.

Table 1. Incorporation *in vitro* of Carbon-14 from Labelled Glucose into the Deoxyribose of Deoxyribonucleic Acid of Rat Thymus Cells

Source of deoxyribose	Specific activity of deoxyribose (counts/min./μmole)	Relative incorporation of carbon-14 into deoxyribose
Adenine deoxyriboside	325	100
Guanine deoxyriboside	420	129
Cytosine deoxyriboside	10	3
Thymidine	21	6

Each of two incubation vessels contained 6 ml. of cell suspension, obtained from eight thymus glands, in Krebs–Ringer phosphate solution (ref. 9) gassed with oxygen and containing glucose-^{14}C (generally labelled). Glucose concentration: 5 mgm./ml.; specific activity of glucose: $9{\cdot}89 \times 10^4$ counts/min./μmole. The vessels were shaken at 37·5° C. for 3 hr., the evolved carbon dioxide being absorbed in potassium hydroxide. At the end of incubation the contents of the two vessels were pooled.

In order to test whether the turnover of the phosphorus moiety of each of the deoxyribonucleotides follows a pattern similar to that of the corresponding deoxyribose moiety, experiments were carried out to determine the incorporation of phosphorus-32 into the four different types of nucleotide derived from deoxyribonucleic acid. Rat thymus cells were incubated in the presence of orthophosphate labelled with phosphorus-32. Deoxyribonucleic acid was isolated as described above and was degraded[10] by deoxyribonuclease and phosphodiesterase from rattle-snake venom[11]. The deoxyribonucleotides were separated using the paper electrophoresis technique of Markham and Smith[12], and their specific activities were then determined. The results of a typical experiment are shown in Table 2. It is clear that there is no difference between the incorporation of phosphorus-32 into the purine and the pyrimidine nucleotides, the specific activities of the four deoxyribonucleotides being of the same order. This finding is in sharp contrast to the observations made on the distribution of carbon-14 in the different deoxyribose moieties (Table 1), and also to the results reported for the sugar of ribonucleic acid where great differences were found between the specific activities of the ribose moieties of the different nucleotides[2].

The striking feature of these observations is the difference in pattern of incorporation of carbon-14 into the deoxyribose moieties of deoxyribonucleic acid and the incorporation of phosphorus-32 into the corresponding nucleotides. The difference in the degree of labelling of these two different moieties of a given nucleotide is of special interest in the study of the metabolism of deoxyribonucleic acid with the

Table 2. Incorporation *in vitro* of Phosphorus-32 into the Nucleotides derived from Deoxyribonucleic Acid of Rat Thymus Cells

Nucleotide isolated	Specific activity (counts/min./μmole)	Relative phosphorus-32 incorporation
Deoxyadenylic acid	465	100
Deoxyguanylic acid	576	124
Deoxycytidylic acid	502	108
Thymidylic acid	647	139

The incubation vessel contained 11 ml. of cell suspension, obtained from six thymus glands, in Krebs–Ringer bicarbonate gassed with 95 per cent oxygen – 5 per cent carbon dioxide (ref. 9). Orthophosphate labelled with phosphorus-32 was added to give a final concentration of 1 μc./ml. Glucose concentration was 5 mgm./ml. The vessel was shaken at 37·5° C. for 3 hr.

aid of labelled precursors. It indicates corresponding differences in the rates of turnover of the two moieties, the renewal of which presumably occurs while the nucleotides form part of the pool of free nucleotides of the cell constituting the precursors of deoxyribonucleic acid. It should be emphasized that the relative rates of turnover of these nucleotides, at least *in vitro*, evidently depend upon the moiety being studied.

It is not yet known whether similar differences in the pattern of incorporation of the two isotopes exist also between the nucleotides of ribonucleic acid; work is being carried out on this particular problem.

I wish to thank Prof. J. S. Mitchell for his interest and Dr. B. E. Holmes for her encouragement and stimulating discussions. I also wish to acknowledge the financial support of the British Empire Cancer Campaign.

ANIMAL PHYSIOLOGY

Failure of Growth in Disturbed Laboratory Rats

Laboratory rats can be very sensitive to disturbances of their accustomed environment or routine, and they may react by modifying their eating and drinking behaviour in various ways[1-4]. If some kinds of disturbance are prolonged, the body-weight may be affected, and we have previously found this a particularly useful measure: rats which were exposed to disturbances either lost weight or they failed to gain it as quickly as undisturbed controls[5,6].

In one of these investigations[6] adult rats were subjected to disturbances of a kind which often occurs incidentally during laboratory experiments: transfer to an unfamiliar room and cages, separation from cage mates, a new form of diet, oral injections. These changes were introduced concurrently, and by the end of the next 24 hr. the rats had eaten and drunk only about half their normal intake and had lost nearly 3 per cent of their body-weight. The environmental changes were maintained for three weeks; by then the rats had not yet made good the loss of weight: a control group had meanwhile gained more than 3 per cent.

Relatively commonplace events seemed, therefore, to have evoked a big reaction, and in the present investigation this kind of situation was analysed further and over a longer period of time. In particular, the aim was to study effects on body-weight: (*a*) when environmental changes were introduced gradually, that is, one by one, and time was allowed for the rats to become adapted before the next change was made; (*b*) during a subsequent period when no further changes were made and the rats were left to 'recover' undisturbed.

Male Lister hooded rats lived under uniform conditions, three to a cage, since weaning and were little handled. When they were 200–210 days old they were allocated at random to two groups of five rats. The 'undisturbed' control group remained in their home cages in the colony room throughout and were merely weighed daily. The 'disturbed' experimental group were also weighed daily, and in addition they were treated as follows:

(1) *Transfer to another room.* The rats stayed in their home cages but were transferred by trolley to another room nearby where the cages were again suspended in standard racks. The temperature (set by thermostat at 68° F.) and the general level of light and noise in the new room were roughly the same as in the colony room; humidity could not be controlled but the fluctuations when measured were fairly similar in the two rooms. The usual diet (41.*b*, pellets) and water continued to be available *ad lib.*

(2) *Change of diet.* Eight days later, a powdered form of diet 41.*b* was substituted for the pellets.

(3) *Segregation.* After a further 8 days, the rats were separated from their cage mates and were re-housed singly in unfamiliar cages of identical pattern.

(4) *Injections.* After 8 days of living singly, and daily thereafter, each rat was given orally by syringe 1 ml./kgm. tapwater.

(5) *Daily change of cage.* Eight days after the injections had begun, each rat was re-housed in an unfamiliar though otherwise similar cage each day. Thus, once an environmental change had been introduced it was maintained, so that by now the rats were living in the new room, on powder food, singly, with a daily injection and in a different cage each day.

(6) '*Recovery.*' After 12 days, no further changes were introduced, injections ceased, and the rats remained—still singly and with powder food—in the same cage for a final 16 days. Throughout the investigation the body-weights and food and water intake were determined, and any environmental changes were made daily between 2.30 and 3.30 p.m. The mean starting weights were: experimental group 317·4 gm., *S.D.* 33·6, controls 323·2 gm., *S.D.* 45·8, and the difference was not significant ($P > 0·05$). All rats seemed in normal physical health throughout.

Fig. 1 shows the mean gains or losses in body-weight for the two groups during the 60 days. The 'undisturbed' controls gained weight fairly steadily throughout, and by the end the average gain was 29·0 gm., *S.D.* 5·4, or about 9 per cent. In the experimental group, however, weights changed relatively little during the first 44 days while the environmental disturbances were taking place. Immediately after all but one of the disturbances there was if anything a slight drop in weight, of the order of 2–3 gm., but this had usually been made good by the time the next kind of disturbance was due; the greatest drop followed the introduction of the new diet, but even this was not statistically significant. The pattern of daily food and water intake roughly reflected the fluctuations in weight; the greatest drop occurred, again, just after the change of diet when the average

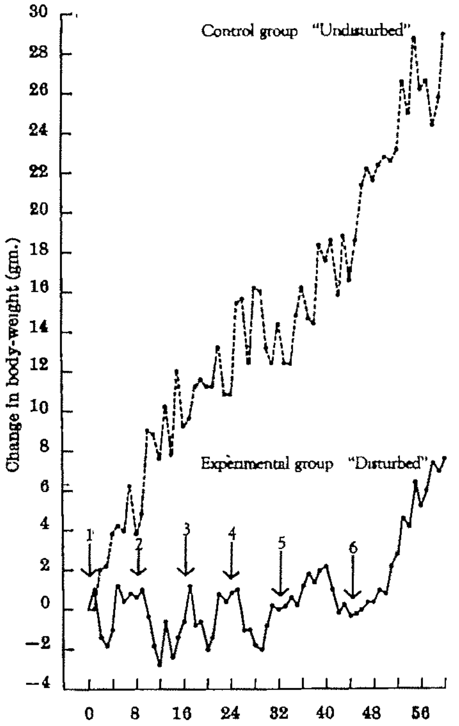

Fig. 1. Arrest of gain in weight in rats subjected to environmental changes. The control group remained undisturbed in the colony room throughout. The experimental group had successively the following treatments: (1) transfer to another room; (2) change in the form of diet; (3) segregation from cage mates; (4) daily oral injections; (5) daily change of cage; (6) 'recovery', that is, no further alterations in the environment were made. The arrows indicate when each kind of treatment began. Weight changes are expressed as mean gains or losses from the mean body-weight of each group at the beginning of the experiment

food and water intake was about a quarter less than usual. Thus at the end of the 'disturbed' period the experimental group still weighed almost exactly the same as at the beginning (mean change − 0·4 gm., *S.D.* 4·2); the controls had meanwhile gained 16·6 gm., *S.D.* 2·4. The net difference between the two groups was therefore 17·0 gm., and these changes in mean weight differ significantly between the two groups ($t = 7{\cdot}05$, $P < 0{\cdot}001$). When 'recovery' began, the weight of the experimental group immediately began to climb, and the graph suggests that they gained weight at a rate roughly parallel to that of the controls. By the end of the 16 days recovery they had gained 8·0 gm., *S.D.* 1·1, slightly less than the corresponding 12·4 gm., *S.D.* 3·9, gained by the controls. The net difference between the two groups at the end of the experiment was therefore 21·4 gm. ($t = 6{\cdot}14$, $P < 0{\cdot}001$), and this makes it seem unlikely that the experimental group was catching up. Food and water intake during the recovery period were very slightly higher than before but did not increase as clearly as body-weight.

These results suggest that the environmental changes led to a temporary arrest in the rats' normal weight gain. Since for practical reasons the order in which the changes were made was the same for all the rats, it is not strictly valid to compare the effects of the different kinds of change with each other. Superficially the effects of each kind of change were fairly similar, and the effect of the change of diet was possibly the greatest. Merely to move the rats from the colony room to another room at the beginning of the experiment (Fig. 1 (1)) had some effect, though this was smaller than the effect previously referred to of making various other changes concurrently[5].

A probable reason for the arrested gain in weight was that the disturbed rats temporarily ate and drank less than usual. Environmental changes of the kind described might, however, also have had other effects, like increased general activity[7,8], less-efficient assimilation of food[9], or loss of heat because of single living[10], and any of these could have helped to keep down body-weight. The experimental group was also, inevitably, handled slightly more than the controls, but handling probably benefits body-weight[11]. Whatever the exact explanation, the results illustrate that common laboratory procedures to which normally little importance might be attached can—at least where rats' body-weight is concerned—have sizeable and lasting adverse effects.

Effects of this kind can sometimes be mitigated by administering small doses of the tranquillizing drug chlorpromazine[6].

Modification of Cholesterosis and Lipidosis of Rats maintained on an Atherogenic Diet

Although the liver is regarded as the primary organ of lipid metabolism, little is known of this metabolic process at the cellular level. Recognizing that the cellular composition of liver is approximately 61 per cent parenchymal and 33 per cent littoral cells[1], I attempted to clarify the participation of hepatic cells in lipid metabolism by studies on the lipid composition of isolated parenchymal and Kupffer cells[2]. This work showed, in reference to the isolated parenchymal cell, an elevated cholesterol-level in Kupffer cells which suggested that these cells actively participated in cholesterol metabolism. Subsequent work indicated that Kupffer cells probably are not involved in the uptake of plasma cholesterol but do participate in its biotransformation or excretion[3].

The present work was designed to investigate the relationship between reticuloendothelial activity, and the ability of the animal to handle an exogenous cholesterol load. If Kupffer cells are involved in the biotransformation or excretion of cholesterol, then during reticuloendothelial hyperactivity one would anticipate increased tolerance to ingested cholesterol.

Table 1. INFLUENCE OF ZYMOSAN ON HEPATIC LIPIDS* OF NORMAL AND CHOLESTEROL-FED RATS

Group	No.	Body-weight (gm.)		Liver (per cent body-weight)	Spleen (per cent body-weight)	Cholesterol			Neutral fat
		Initial	Final			Free	Ester	Total	
Control	9	209 ± 6 6	265 ± 11·8	3·7 ± 0·19	0 23 ± 0·01	1 82 ± 0 08	0·71 ± 0·11	2 53 ± 0·10	9 14 ± 2·25
Control and zymosan	9	206 ± 11 5	211 ± 6·1	6 3 ± 0·24	1·10 ± 0 18	2·18 ± 0·09	0·35 ± 0 12	2 54 ± 0·14	6·81 ± 0·71
Cholesterol-fed	9	201 ± 6·6	198 ± 13 2	5 4 ± 0 25	0·24 ± 0·01	4·60 ± 0·29	50·56 ± 4 25	54·57 ± 4·55	38 93 ± 3·34
Cholesterol-fed and zymosan	9	212 ± 6·8	168 ± 4·9	7·1 ± 0 48	0·78 ± 0 09	3·45 ± 0·15	17·20 ± 2·74	20·98 ± 2·77	17·89 ± 1·82

* Lipid values are expressed as mgm./gm. of fresh tissue weight ± standard error.

This would be reflected by lower tissue cholesterol-levels. Since reticuloendothelial blockage cannot be produced[4], the influence of reticuloendothelial hyperactivity on liver cholesterol-levels was studied in rats maintained on normal and high cholesterol, high fat diets. The reticuloendothelium was stimulated by the intravenous injection of the yeast extract, zymosan, in the amount of 10 mgm. administered on alternate days. Thirty-six male rats were initially employed, 9 normal rats served as controls and received saline injections, while 9 additional normal rats received zymosan. The remaining 18 rats, 9 of which received zymosan, were fed an atherogenic diet similar to that employed by O'Neal *et al.*[5], which contained the following :

	Per cent		Per cent
Casein 'vitamin free'	19·9	Thiouracil	0 3
Sucrose	18·1	Choline chloride	0·2
Salt mix (U.S.P. XIV)	7 3	Sodium cholate	1·8
Alphacel (non-nutritive bulk)	9·1	Butter	37 0
Vitamin diet fortification mixture	1·8	Cholesterol	4·5

Daily determinations were made on body-weight and food-intake. At the end of the 14-day period liver total and free cholesterol, phospholipid and neutral fat were determined as previously described[6].

In agreement with previous observations[7] the administration of zymosan to rats maintained on 'Purina' show significantly increased weight of liver and spleen. The liver free and ester cholesterol fractions were not significantly altered in the normal rats given zymosan. Maintenance of rats on the atherogenic diet for 14 days significantly elevated the free cholesterol and profoundly increased the ester cholesterol and neutral fat. The administration of zymosan to rats maintained on the diet induced a comparable increase in liver and spleen weight despite the elevated dietary thiouracil level. Zymosan significantly reduced the accumulation of free and ester cholesterol and neutral fat in the liver. No correlation could be demonstrated between changes in body-weight and liver cholesterol-levels. Dietary-intake was not significantly different in the saline- and zymosan-treated groups maintained on the atherogenic diet. A significant reduction in plasma ester cholesterol was also noted in the zymosan-treated group, although no change was observed in the concentration of various lipid fractions of the spleen.

A pair-feeding experiment was also carried out for a 5-day period with 6 male rats maintained on 'Purina' chow to which 1 per cent cholesterol and 0·5 per cent sodium cholate was added. This would eliminate any question of body-weight alterations and also evaluate the effectiveness of zymosan in preventing liver cholesterol accumulation at lower levels of dietary cholesterol intake. These animals lost a mean 9 per cent of their initial weight. In the untreated cholesterol-fed group the liver ester cholesterol concentration was significantly elevated (Table 2). As observed in the previous studies, a significant reduction (88 per cent) occurred in the ester cholesterol fraction of the rats which were daily injected intravenously with zymosan in the amount of 5 mgm./day.

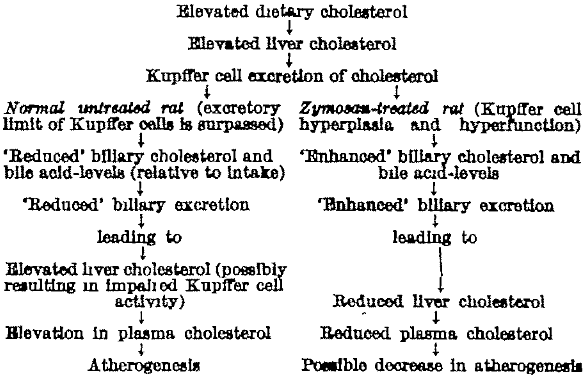
It is apparent that a major determinant to elevated plasma and liver cholesterol-levels of rats maintained on a high cholesterol diet is the functional state of the reticuloendothelium and specifically the number and activity of Kupffer cells.

Table 2. EFFECT OF ZYMOSAN ON LIVER CHOLESTEROL-LEVELS* OF PAIR-FED RATS ON A 1 PER CENT CHOLESTEROL DIET

Group	Body-weight (per cent)		Cholesterol		
	Liver	Spleen	Total	Free	Ester
Normal	3·41	0 19	2·16	1·91	0 25
Cholesterol-fed	3 01	0 24	18·03	3·20	14 83
Cholesterol-fed + zymosan	3 95	0 69	4 48	2 26	1·82

* Mean values are expressed as mgm. of cholesterol per gm. of fresh tissue.

Stambul[8] has previously summarized evidence for the role of Kupffer cells in the biliary excretion of cholesterol. In view of our previous observations[2,3] and the known mode of excretion of cholesterol which in the rat is an array of bile acids, the following concept can be proposed. This concept indicates the possible mechanism whereby zymosan prevents the accumulation of liver and plasma cholesterol and the possible etiology of hypercholesterolæmia and lipidosis in the untreated animals :



Elevated dietary cholesterol
Elevated liver cholesterol
Kupffer cell excretion of cholesterol
Normal untreated rat (excretory limit of Kupffer cells is surpassed)
Zymosan-treated rat (Kupffer cell hyperplasia and hyperfunction)
'Reduced' biliary cholesterol and bile acid-levels (relative to intake)
'Enhanced' biliary cholesterol and bile acid-levels
'Reduced' biliary excretion
'Enhanced' biliary excretion
leading to
leading to
Elevated liver cholesterol (possibly resulting in impaired Kupffer cell activity)
Reduced liver cholesterol
Elevation in plasma cholesterol
Reduced plasma cholesterol
Atherogenesis
Possible decrease in atherogenesis

In view of the functional complexity of the reticuloendothelium, and the role of zymosan in immunological mechanisms, other phases of reticuloendothelial activity besides reticuloendothelial involvement in cholesterol metabolism could be the mechanism of the protective action of zymosan. However, the present findings apparently demonstrate a new concept in the regulation and prevention of hepatic lipidosis and cholesterosis and possibly experimental atherosclerosis through the activation of the reticuloendothelium.

Work to substantiate further this hypothesis is now in progress.

The accumulation of lipid in Kupffer cells is reported to be most marked in diabetes[9], a condition associated with impaired reticuloendothelial activity[10] as well as hyperlipæmia and increased incidence of atherosclerosis.

This work was supported in part by a grant from the U.S. Public Health Service (*H*-2320) and the U.S. Atomic Energy Commission.

Diathelic Immunization of Sheep against a Rat Cancer

THE term 'diathelic immunization' has been introduced by B. Campbell *et al.*[1], who instilled different antigens into the orifice of the milk gland (in cows) and obtained colostrum and milk with high titres of antibodies against the antigens used. They consider the milk gland as an exocrine reticulo-endothelial gland.

It has been shown by previous work that resistant rats (strain *bWr*, or black-Walker-resistant, inbred in our laboratory) produce, after implantation of the Walker 256 tumour, factors inhibiting the growth of this tumour in susceptible rats, when resistant immune blood serum is injected into them intraperitoneally[2], and that susceptible rat sucklings are protected against the growth of the tumour by the ingested milk when nursed by the resistant immune rat females[3].

Further, it has been shown that spleens of resistant rats immunized by the tumour *in vivo* continue the production of antitumour factors when explanted in tissue culture[4], and that an active immunization *in vitro* of spleens from normal resistant rats against the tumour used is possible[5].

In the present experiments, we instilled repeatedly, at weekly intervals, by means of a glass canule, several million of live Walker 256 tumour cells suspended in about 0·5 ml. of saline into the orifice of the milk glands of two sheep a month or more after parturition. Instillation was carried out on the evening after the last (third) day's milking. 12 hr. later (on the next morning) the milking was continued.

There was a massive cellular reaction in the milk from the instilled udders, changing gradually, in the course of the immunization, from nearly exclusively polymorphonuclear (segmented) leucocytes to more and more mononuclear cells with a large plasmatic component. (This cellular reaction will be described in detail and analysed in a separate communication.) There was also a strong decline in the milk output beginning at 18 hr. after instillation, but in the following 3–5 days milk output returned nearly to normal. There were no signs of bacterial inflammation of the instilled udders or of the animals themselves, although some capsulated bacteria have been seen in cell-preparations from the milk; milking was done under the usual non-aseptic conditions. The cellular reaction as well as the inhibition of lactation seem to vary from individual to individual; both were much stronger in one sheep than in the second.

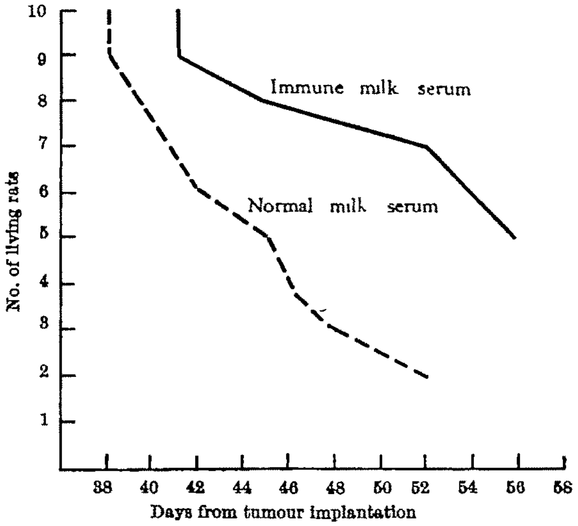

Fig. 1. Deaths from tumour in rats injected with normal and immune milk serum

The 'immune' milk was used in several ways.

(1) A neutralization test was performed. Rats were implanted with equal doses of the Walker 256 tumour cells, which had been incubated for 3 hr. at 37° C. in the normal and immune milk (only the milk fat was separated by centrifugation). After incubation, the cells were centrifuged from the milk and resuspended in saline before implantation. A control set of rats was implanted with non-incubated tumour cells (from the same original suspension), in saline. Results are given in Table 1.

Table 1

Incubation	Tumours*	
None	7/10	(70 per cent)
In normal milk	17/20	(85 per cent)
In immune milk	9/20	(45 per cent)

* Ratios of rats with tumours to the total number of animals used; after 30 days no new tumours appeared.

(2) Milk serum was prepared by adding some drops of dairy rennet and centrifuging the curdled milk, and injected after Seitz-filtration intraperitoneally into susceptible rats bearing implants of equal numbers of live Walker 256 cells. Results of two groups of 10 male rats weighing 120–150 gm. at the start of the experiment, and given, from the day of tumour implantation, 2 ml. daily of normal or immune milk serum for 40 days, are illustrated in Fig. 1. In the normal series there are 2 non-takes in 10, in the immune series 5 non-takes in 10.

It is to be noted that the gains in weight of rats given the immune milk serum were lower than of those given the normal milk serum or of the controls. The gains in weight of different groups after 15 days from the beginning of the experiment are given in Table 2.

Table 2

Injections	Mean gain in weight
None	16 per cent
Normal milk serum	15 per cent
Immune milk serum	8 per cent

After 15 days, the weight control is obscured by the growing tumours. On the whole, the anti-rat component of the heterologous (sheep) immune milk under given conditions seems negligible; all rats surviving without tumours, both in the experimental as well as in the control groups, seem undamaged and live normally to date.

(3) Cytotoxic effect of the immune milk serum was proved by the method of unstained cell count[6]. Freshly prepared tumour cells were suspended in normal and immune milk serum, counted, incubated at 37° C. for 4 hr. and counted again. Table 3 indicates results of these counts on 6 subsequent days, where the influence of milk sera from three different sheep after different numbers of immunizations are compared. In all these experiments, drops of complement were added (guinea pig serum); but we have found that fresh immune milk serum has a cytotoxic activity of equal degree without the addition of complement.

Table 3

Sheep No.	No. of immunizations	Cell count (per cent) before incubation	Cell count (per cent) after incubation, mean from 6 days	Range
1	none	100	96	82–100
2	3	100	57	48–67
3	5	100	18	10–26

These results, considered with previous work, seem to prove that any system capable of immune reaction is able to produce anti-tumour factors passively transmissible, and active in inhibiting tumour growth in susceptible animals. Furthermore, there seems to be a possibility of producing relatively large amounts of these active substances by a procedure which is very simple and obviously harmless for the producing animal. Thus some kind of immunotherapy could be used in combination with other therapeutic means in cancer.

Attempts to separate the active substances from the milk serum (as milk globulins), as well as to purify them from the anti-species component, are proceeding. Also the possible role of the cellular milk reaction and the eventual use of such cells are being considered.

Fibrinolytic Activity of Cirrhotic Liver

Several investigators have observed increased fibrinolytic activity in the circulating blood in cases of liver cirrhosis in man[1–4]. The cause of this activity is unknown, though a toxic effect similar to that produced in dogs by chloroform or peptone has been suggested. Such a mechanism could possibly be involved in an acute process, but could barely explain the prolonged periods of increased fibrinolytic activity observed in cases of liver cirrhosis.

A mechanism by which the fibrinolytic system in blood is activated by an activator of plasminogen released from injured tissue is apparently excluded, since such fibrinolytic activity has been reported to be absent from liver tissue[5–8].

We have now investigated the fibrinolytic activity of tissue from a series of cirrhotic livers, estimating the concentrations of plasminogen activator by a quantitative method[9]. The results are given in Table 1. It is seen that the samples from the cirrhotic livers show varying degrees of fibrinolytic activity. When compared with the concentrations in normal human organs[8] some of the pathological liver samples even range among the most active tissues in the human organism. Another significant observation is a slight increase in activity of apparently normal livers with age (Table 1).

Table 1. Fibrinolytic Activity of Apparently Normal and Cirrhotic Human Livers estimated as Concentration of Plasminogen Activator in Units of a Standard Preparation per gm. Fresh Tissue

In accordance with views previously presented[10] fibrinolysis participates in wound healing. There are now several indications that vascularized connective tissue, occurring normally in the organism or formed as response to tissue injury, is characterized by high fibrinolytic activity caused by a plasminogen activator. Thus normal animal and human meninges are among the most active tissues so far investigated[11]. High activity was also recorded in the adventitia of arteries[12] or in the walls of veins[13] as well as in the kidney capsula[14]. The activity of the arterial adventitia increases with age[15], probably reflecting increased vascularization. Similarly, high fibrinolytic activity was found in connective tissue from samples of healed human myocardial infarcts[16] in contrast to the fairly low activity of normal human myocardium. The last two examples apparently represent a response to tissue injury similar to that occurring in liver cirrhosis or produced during ageing. The lack of fibrinolytic activity of blood in cases of primary carcinoma of the liver[3] probably points to a disturbed tissue repair process.

Since plasminogen is probably formed in the liver, it is easy to visualize that dangerous conditions could arise when high concentrations of a plasminogen activator are found in close contact with plasminogen-producing liver cells. Apart from interfering with local wound healing and tissue repair, fibrinolytic activity could easily escape into the blood system. Hence, it is possible to understand the physiological basis of the morbidity of diseases leading to cirrhosis of the liver.

The results are also of interest in connexion with the low incidence of arterial disease recorded in patients with liver cirrhosis by some authors. The observations support the thrombogenic theory of the pathogenesis of arteriosclerosis, as set forth by Duguid[17,18], and strengthen the concept of a dynamic balance between fibrin formation and fibrinolysis as a regulator of this process[10,19].

This investigation was aided by grants from the Josiah Macy Jr. Foundation, New York, and the National Danish Association against Rheumatic Diseases. Details will be published elsewhere.

Rapid Contractile Properties of Isolated Mammalian Arteries

STRONG indirect evidence is now accumulating[1,2] in support of the old idea that large mammalian arteries may be capable of contracting and relaxing at least as rapidly as the heart. Direct evidence based on studies of isolated arteries is still lacking, and this remains a major stumbling block in accepting the implications of much of the recent work.

Paton's technique[3] has been used to study the behaviour of 2–3 cm. lengths of dog's common carotid, femoral, hepatic and splenic arteries, and of sheep's hepatic and splenic arteries. The excised artery was tied on a glass cannula which formed a closed system connected to a manometer (Hansen condenser). The free end and any branches were ligated with fine silk, and the artery was stretched to about three-quarters of its natural length by a stiff silver wire passed through the cannula and along the lumen of the artery. This wire electrode was led through a seal into the air, and another silver electrode dipped into the bath in which the artery was immersed. Tyrode's solution at 37° C. was used in most experiments, and saturated with 5 per cent carbon dioxide and 95 per cent oxygen. From ½ to 4 hr. after excision all the 34 arteries examined were capable of raising the pressure within the closed system when an electrical stimulus was applied across the two electrodes. To square-wave stimuli the chronaxie was about 20 m.sec. and the rheobase 1–4 V. Responses were obtained equally easily whether the central lumen electrode was positive or negative. The highest rise of pressure obtained with a single shock (of an intensity and duration just less than that which caused irreversible damage to the preparation) was 15 mm. mercury. Much higher pressures could be obtained by repetitive stimulation. It was difficult to elicit any response if the starting pressure in the system exceeded 200 mm. mercury, and low pressures were used in most experiments because of the difficulty of stopping very small leaks.

The time course of a typical single contraction is shown in Fig. 1*A*, and the latency of onset of the contraction is shown at a faster film speed in Fig. 1*B*. Latency is 80 m.sec., time to peak pressure 2–3 sec., and time to full relaxation 5–10 sec. The speed of relaxation was usually greater at high internal pressures, at least within the physiological range. The contraction was reversibly abolished by increasing external potassium concentration to 130 m.equiv./l. (isosmotic with normal Tyrode solution); but it could still be elicited in the presence of atropine (10^{-7}) and dibenyline (10^{-6}) which had been allowed to act for 30 min. Slow repetitive stimulation produced pressure oscillations at frequencies up to about 0·7 c./s. (Fig. 2*A*). If an oscillating pressure was introduced into the system, the amplitude of oscillation was increased by stimulation (Fig. 2*B*), presumably because of increased rigidity of the muscular wall. The long chronaxie and the failure of drugs to influence contraction indicate that muscle cells are being excited directly. So far it has not proved possible to excite contraction through nerves, presumably because in this preparation the nerve supply is damaged. Even when arteries were tested in fresh plasma 5 min. after excision, there was no evidence at all of excitation of nerves. By analogy with other excitable tissues, it seems probable that

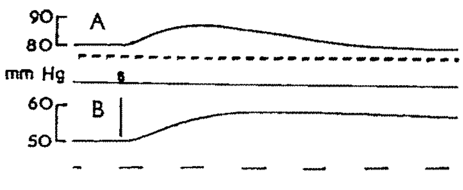

Fig. 1. Time-course of the contraction to a single stimulus (*S*) of a 2-cm. length of sheep's hepatic artery. (*A*) From above down: the stimulus (18 V., 20 m.sec., isolated from earth and fed to the cathode-ray oscillograph through capacitors); lumen pressure (scale on left in mm. mercury); time marking (½ sec.). (*B*) Onset of a contraction (at a faster film-speed) following a stimulus of 120 V. for 150 μsec.: time marking, ½ sec.

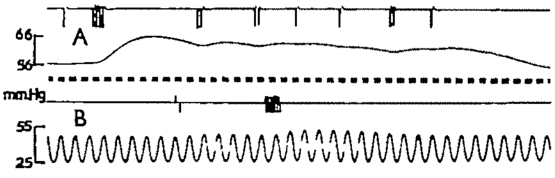

Fig. 2. (*A*) Response of a dog's hepatic artery to short bursts of repetitive stimulation. Top trace shows the stimulus record (retouched) and lower trace the pressure record. (*B*) Effect of an oscillating pressure introduced in the same preparation. Stimuli (upper trace, retouched) cause a rise of mean pressure and of oscillation amplitude (lower trace). Time marking (¼ sec.) in between the records is the same for both

excitation through the normal nerve supply will produce more rapid effects.

Since efferent sympathetic activity normally occurs in bursts with a cardiac rhythm[4], it seems possible that rapid response of large arteries to such nervous activity could explain a number of curious phenomena observed in the peripheral arterial pulse contour, notably the augmentation of systolic peak pressure towards the periphery and perhaps also the dicrotic wave. It is noteworthy that atropine and procaine can abolish both these phenomena[5], even though there may be no change in mean arterial pressure.

Thyroidal Control of Radiophosphorus Metabolism in Salmon

The part played by the thyroid gland in teleost metabolism has been investigated by many workers. In cold-blooded vertebrates it appears to be concerned more with growth than with general metabolism[1]. However, there is a great deal of controversy on practically every aspect of thyroid physiology. In higher vertebrates, the parathyroid plays an important part in the mineral metabolism. Fishes have, so far as known, no parathyroid. It has been suggested[2] that the ultimobranchial body in the teleost is the homologue of the parathyroid but as yet nothing positive has been established regarding this hypothesis. Fishes are able to control mineral metabolism within narrow limits; but there is scarcely any information concerning the role of the endocrines in this regulation. Radioisotopes are being used to carry out experiments to find out whether the thyroid gland has any influence on mineral metabolism in fishes.

In fishes the thyroid gland is divided into innumerable follicles in the region of the ventral aorta, hence surgical thyroidectomy is impossible. Yearling salmon, *Salmo salar* L., were divided into two groups of which one was maintained in 0·3 per cent solution of thiourea, referred below as treated. The other was used as control. The fishes were kept in thiourea solution for two weeks, the solution being changed every three days. After two weeks the fish were transferred to fresh aquaria to which sufficient phosphorus-32 had been added to give an activity of 2,500 counts per min. per ml. Aquaria for treated fish also contained 0·3 per cent solution of thiourea. At regular intervals starting from 2 hr. the tissues (liver, kidney, muscle and bone) were prepared for counting. The readings were corrected for decay and checked against a uranium standard. Carrier-free phosphorus-32 used was received from Atomic Energy of Canada, Ltd., in the form of phosphoric acid in diluted hydrochloric acid. In both the sets of experiments, bone took up the maximum activity, followed by liver, kidney and muscles. The uptake was always more in the treated set than the control. In the control, 40·1 per cent of phosphorus-32 was absorbed, whereas in the treated 50·3 per cent was utilized.

Another set of experiments was arranged to throw further light on the problem. The fishes were divided into three groups. One of them was injected with 0·2 ml. of 0·1 per cent solution of thiourea, the other with 0·2 ml. of 0·1 per cent solution of l-thyroxine and the third with 0·2 ml. physiological saline to serve as control. The injections were repeated again after three days. After a lapse of three days the fish were transferred to solutions of phosphorus-32 which gave an activity of 2,500 counts per min. per ml. In these experiments the uptake of radiophosphorus in bone and liver was studied. In the control, the fishes took up 39 per cent, fishes injected with thiourea absorbed 52 per cent and thyroxine-injected fishes utilized 63 per cent of phosphorus-32.

Thiourea had been used in the above experiments to destroy the thyroid gland and so to check its activity; but the histological studies showed that it was not achieved. Thyroid follicles were still present lined with low epithelial cells and were full of colloid. Administration of antithyroid drugs either abolishes or retards the ability of thyroid gland to synthesize thyroxine[3]. As a consequence of the cessation of thyroxine synthesis, the level of circulating hormone falls and the pituitary immediately responds by secreting additional amounts of thyrotropin which stimulates the thyroid so that hypertrophy of the gland results. This then shows that destruction of thyroid can only be achieved after treating the fishes with antithyroid drugs for considerably longer times.

The results of the experiments can be interpreted that in the fishes treated with thiourea the thyroid was stimulated indirectly (by thyrotropin secreted by the pituitary gland) and so the uptake of radiophosphorus was more than the control. In fishes treated with thyroxine the stimulation was direct and so the uptake was maximum. Detailed results of the experiments will be published elsewhere.

Complete thyroidectomy can be achieved by repeated doses of radioiodine[4]. Further work to study the effect of hypophysectomy and destruction of thyroid by radioiodine upon mineral metabolism is under investigation.

My thanks are due to Prof. F. R. Hayes for facilities, guidance and encouragement, and to the National Research Council of Canada for awarding a post-doctorate fellowship.

Use of Chorionic Gonadotropin to prevent Early Embryonic Mortality in Temporarily Fasted Mice

WHEN studying the pathogenesis of the infertility in female mice caused by depriving them of all food for short periods during early gestation[1], it was found that the immediate cause was either failure of implantation or death of the embryo after implantation. In the latter case, it appeared from the histopathology that the primary lesion occurred in the deciduoma. This was followed by the death of the embryo, possibly due to interference with its nutrition.

The minimal starvation required was the 48-hr. period from the fourth to sixth day after œstrus or third to fifth day after the formation of the copulation plug. Such fasting rendered all matings infertile. However, when injections of 5 I.U. of chorionic gonadotropin were given once daily to each of ten mice during the period when they were being starved, the embryos of all mice survived until at least the third day after the end of the fast. When examined at this time none of the twelve control mice, fasted but not injected, was pregnant. It was assumed from the results of earlier work that embryos had developed but had died and been reabsorbed. When chorionic gonadotropin was given to 16 mice in a third group, over the period from the start of starvation until five days after its end, the embryos of ten appeared normal on the sixth day after the end of fasting. The embryos of three were starting to degenerate and three mice were not pregnant. Progesterone in daily doses of 0·5 mgm. had a similar protective effect.

This suggests that the pathogenesis of the embryonic mortality involves the anterior pituitary–ovarian endocrine system.

Oxygen Consumption by Tissues from Rats injected with L- or D-Thyroxine

It has been shown by a number of investigators that L-thyroxine is more active *in vivo* than is D-thyroxine[1]. In most *in vitro* systems, however, the D- and L-isomers are equally effective. The equal activity of D- and L-thyroxine in altering the morphology of mitochondria and in 'uncoupling' oxidative phosphorylation are examples of this[2,3]. Previous experiments[4] in this laboratory have compared the distribution and excretion of labelled D- and L-thyroxine labelled with iodine-131 following a single injection of a tracer quantity of each compound into the tail vein of the rat. Initially, D-thyroxine was concentrated to a greater extent in the liver and kidney than was L-thyroxine, but after 24 hr. the concentrations were approximately equal. However, the concentration of D-thyroxine in tissues such as muscle, brain and skin was much less than the concentration of L-thyroxine. This difference in distribution to the peripheral tissues was of such magnitude as to suggest a possible basis for the different activities of the two isomers *in vivo*. Others have shown[5,6] that the oxygen consumption of certain tissues (for example, liver, kidney and muscle) from animals injected with DL-thyroxine is significantly greater than normal, whereas that of other tissues (for example, brain) is not increased. The current investigation was undertaken to determine whether the differences demonstrated in the distribution of the two isomers could be correlated with a difference in their ability to stimulate the oxygen consumption of the several tissues.

Adult male Wistar rats, 4–6 weeks post-thyroidectomy, were used in this experiment. The treated animals were injected subcutaneously for 4 days with either D- or L-thyroxine (6 mgm./kgm.). (D-thyroxine was provided through the kindness of Dr. L. G. Ginger, of Travenol Laboratories, Inc., Morton Grove, Illinois. L-thyroxine was furnished through the kindness of Dr. A. E. Heming, of Smith, Kline and French Laboratories, Philadelphia, Pa.) The sodium salt of each isomer was dissolved in 0·02 *N* sodium hydroxide and 0·9 per cent sodium chloride. All animals were fasted 24 hr. before being anæsthetized with ether and exsanguinated. The various tissues were rapidly excised and placed in ice-cold Krebs–Ringer–phosphate solution. All tissues were prepared in duplicate. Liver, kidney and heart slices prepared by the Deutsch technique[7] were made smaller by cutting with scissors. Each diaphragm was cleared of fat and connective tissue, and its central portion was removed; the hemi-diaphragms then were placed in separate flasks. Specimens of brain were prepared by removing the larger tracts of white matter and forcing the remaining tissue through a syringe and No. 18 needle. After weighing, the tissues were placed in chilled Warburg flasks containing the incubation medium (Krebs–Ringer solution buffered with 0·01 *M* sodium phosphate with 100 mgm. per cent glucose). The flasks were gassed with 100 per cent oxygen for 5 min.; oxygen consumption was determined at 37° C.

It may be noted in Table 1 that with slices of liver from animals injected with either D- or L-thyroxine the oxygen consumption is almost identical; in both cases the Qo_2 is significantly greater than that of the control. The same result was also obtained with kidney slices. With heart and diaphragm, on the other hand, there is a significant difference between the animals injected with L-thyroxine and those injected with D-thyroxine; in both tissues the Qo_2

Table 1. OXYGEN CONSUMPTION BY VARIOUS TISSUES FROM RATS INJECTED WITH L- OR D-THYROXINE

	Control Qo_2 (10 rats)	L-Thyroxine Qo_2 (10 rats)	D-Thyroxine Qo_2 (10 rats)	P Control vs. L-thyroxine	P Control vs. D-thyroxine	P L-Thyroxine vs. D-thyroxine
Liver	1·40 ± 0·06*	1·94 ± 0·03	1·91 ± 0·07	< 0·001	< 0·001	> 0·1

* Standard error of the mean, Qo_2 = cu.mm. of oxygen per mgm. wet weight per hr.

was higher with tissues from animals injected with the L-isomer. The Qo_2 of brain was slightly lower than control values in both series of treated animals. The present results support the thesis that the difference in physiological activity between the two isomers of thyroxine is probably secondary to their different distributions *in vivo*.

Pitch Discrimination in Orthoptera (Insecta) demonstrated by Responses of Central Auditory Neurones

For about twenty years, since Pumphrey's review of hearing in insects[1], the commonly accepted view has been that the auditory organs of insects convey to the central nervous system considerable data about the pattern of amplitude of impinging sounds. There has been, on the other hand, no good evidence that the primary sensory nerves can or must convey cues as to the pitch of a sound stimulus and there has been no good evidence that the central nervous system responds differentially to one pitch rather than another, irrespective of intensity.

By recording from the pro-mesothoracic connectives of *Locusta migratoria* and *Schistocerca gregaria* (Acrididae) or from the cervical connectives of *Acheta domestica* (Gryllidae) with external electrodes, it is possible to identify a few ascending internuncial neurones which are excited at the sudden onset of a pure tone or short pulse of sound. The receptor is the tympanal organ, as may be shown by section of its nerve. The curve of threshold strength plotted against stimulus pitch for the single post-ganglionic neurone with the lowest threshold does not correspond with the analogous curve obtained by recording the summed action potentials of the sensory nerve, as initiated by the same stimuli. When recording from the sensory nerve the threshold was taken to be the stimulus strength required to produce a response of a fixed height on the oscilloscope screen, about one-twentieth of the maximal response.

The threshold strength of sound pulses required to elicit a response in a post-ganglionic neurone is raised by the simultaneous sounding of a continuous note. At the same time the pitch range of maximum sensitivity is moved as shown in Fig. 1. The direction of the shift of optimum pitch is away from the pitch of the continuous note. These results have been obtained with each of the above species of Orthoptera.

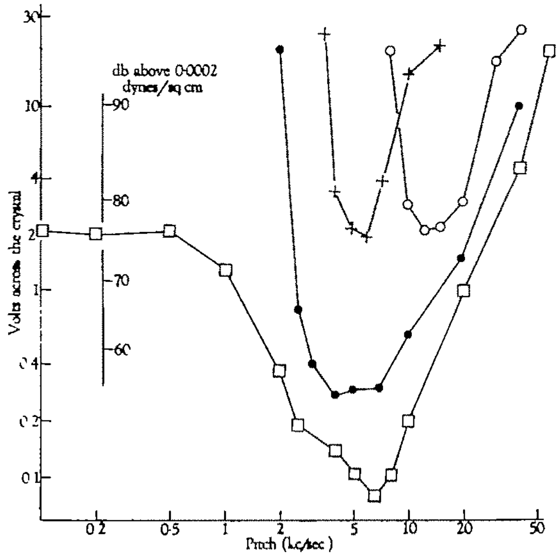

Fig. 1. Sound intensity threshold curves for auditory responses of *Locusta migratoria* with tone pulses of various pitch. □, From the tympanal nerve, the threshold being taken as the intensity required to give a twentieth of maximal response height. ●, From a single ascending neurone of the ventral cord. +, From the same neurone in the presence of a continuous tone at 15 kc./s. ○, From the same neurone with a continuous tone of 4 kc./s. Each point is the average of two readings, one taken ascending, the other descending the scale. The ordinate of sound intensity (db. above 0·0002 dynes/sq. cm.) is useful only up to 15 kc./s. and in the lower ranges is accurate to about 10 per cent

The difference between the pre- and post-ganglionic threshold curves is such that the metathoracic ganglion of the locusts responds differentially in favour of tone pulses of high pitch and rejects those of low pitch although they excite axons of the tympanic nerve. In the cricket, on the contrary, the prothoracic ganglion discriminates in favour of pulses in a low pitch-range of 0·5–3 kc./s., though the thresholds measured in the tympanic nerve do not begin to rise steeply until a range of 20–30 kc./s. is reached. Therefore, this evidence of discrimination indicates that the ganglion 'selects' certain axons, and this in turn means that discrimination has already occurred at the sense organ although formerly not observed by electrical recording from the whole bundle. The second piece of evidence, that the optimum pitch for the response to a pulse is shifted by a continuous note of differing pitch, does not indicate whether the mechanism lies in the ganglion or in the sense organ. A suggested explanation of these two sets of results is that there are at least two groups of sensory neurones, one group more easily excited by pulses of low pitch, one by pulses of high pitch. The group of neurones which become accommodated to a continuous note of one pitch would not then include those which are accommodated to a note of widely differing pitch.

Confirmation that different groups of sensory neurones are excited by the sudden onset of pure tone pulses of differing pitch comes from careful examination of the summed action potentials of whole tympanic nerves of the above two species of Acrididae. In preparations in which there is a favourable arrangement of the electrodes in relation to the short-circuiting of action currents, the summed action potentials initiated by pulses of one pitch cannot be matched in exact form by those initiated by pulses which differ only in pitch, no matter how relative stimulus intensities are adjusted. The response is of a number of axons in each of which there appears to be only one impulse when sound pulses of 10–20 m.sec. are used. Therefore sound pulses of differing pitch initiate impulses in distinct groups of sensory axons.

A possible mechanism for pitch discrimination is suggested by the structure of the tympanal sense organ of the above species. The sensory neurones are not situated all at the same point but are separated into groups. In agreement with the arguments of Pumphrey[1] the sense organ behaves as a displacement receptor without resonance, but it is still possible for pulses of differing pitch to initiate differing modes of vibration so that the groups of sensory neurones are not stimulated always in the same ratio. Such a mechanism would account for the small size of the observed effects. Certainly the mechanism of analysis is far inferior to that of the mammalian ear, but would provide improved discrimination of biologically important noises from a background disturbance.

HÆMATOLOGY

Mechanism of Clot Lysis

The availability of a large number of inhibitors of proteolytic enzymes, as well as the availability of highly purified streptokinase, plasminogen and plasmin, suggested to me the investigation of the nature of the enzyme or enzymes capable of dissolving fibrin clots. Proteolytic enzymes in general, but more particularly trypsin and chymotrypsin, are known for their ability to digest fibrin clots; certain snake venoms can also do this. The proteolysis of fibrinogen and fibrin by venoms, trypsin or plasmin appears to vary, depending upon which of the enzyme is used. The clotting of fibrinogen is the result of the splitting of an arginine peptide bond in the fibrinogen molecule[1]; this tends to produce a product (fibrin) which is much less susceptible to hydrolysis by trypsin and venoms than the parent substance, fibrinogen[2,3]. Fibrin, on the other hand, is as sensitive to plasmin as is fibrinogen[3].

I wish to report here some attempts made to distinguish a true fibrinolytic enzyme from other proteolytic enzymes which can also dissolve clots.

Fibrinolytic activity as defined by the ability of a substance to dissolve a clot is measured by noting the time required to dissolve a standard fibrin clot under specified conditions. Five-hundredths ml. aliquots of a solution containing various concentrations of the substance to be tested are mixed with 0·1 ml. portions of 0·4 per cent purified bovine fibrinogen[4] in 0·05 *M* veronal buffer of *p*H 7·4 and then to each sample is added 0·05 ml. of thrombin solution containing 10 units of thrombin per ml.; the clot formed in this mixture is kept at 37° C. in an incubator. The time required for lysis (complete dissolution) of the clot is noted in each case. The proteolysis of urea-denatured hæmoglobin has been carried out by the method of Anson[5] and the hydrolysis of synthetic amino-acid esters by the method of Troll *et al.*[6].

Table 1. HYDROLYSIS OF LYSINE ETHYL ESTER BY STREPTOKINASE-ACTIVATED HUMAN SERUM IN THE ABSENCE AND PRESENCE OF AN INHIBITOR, ε-AMINO-CAPROIC ACID

	μM of lysine ethyl ester hydrolysed
Human serum	4·2
Streptokinase + human serum (incubated and then added to the substrate in the presence of amino-caproic acid)	18·6
Streptokinase + human serum + amino-caproic acid (incubated and then added to substrate)	3·4
Streptokinase + amino-caproic acid (incubated and then added to the substrate containing plasminogen (or streptokinase)	10·8

1 ml. of human serum was ten times diluted; to 1 ml. of this diluted serum, 1 ml. of streptokinase containing 1,000 units per ml. and 0·1 ml. of saline or amino-caproic acid are added. 0·2 ml. of this mixture was used in each experiment.

During the course of the experiments it was observed (Table 1) that a preincubated mixture of streptokinase and human plasminogen (that is, proactivator: in human blood the proactivator has been supposed, by some investigators, to be identical to human plasminogen) can hydrolyse synthetic amino-acid esters like lysine ethyl ester in the presence of ε-amino-caproic acid, although a pre-incubated mixture of streptokinase, plasminogen and the inhibitor (ε-amino-caproic acid) cannot do so An appreciable amount of hydrolysis of lysine ethyl ester was, however, noted on the addition of streptokinase (or plasminogen) and ε-amino-caproic acid to a reaction mixture containing the substrate and plasminogen (or streptokinase). Similarly, hydrolysis of this synthetic substrate by plasmin, whether it is prepared from streptokinase-activated human plasminogen (serum) or after treatment of bovine plasma with chloroform or trypsin, is not inhibited by ε-amino-caproic acid. The results indicate that ε-amino-caproic acid can strongly inhibit the reaction of streptokinase with plasminogen to form an activator; once the activation process involving these two substances has occurred ε-amino-caproic acid cannot inhibit the hydrolysis of lysine ethyl ester any further.

As has previously been reported by Sarkar and Devi[7] I have also noted (Table 2) a very strong inhibition of clot lysis by ε-amino-caproic acid if streptokinase-activated human plasminogen (or serum) is used as a lytic agent; inhibition, to a much less extent, is observed if one uses purified plasmin prepared by any of the methods mentioned above. When the concentration of ε-amino-caproic acid is increased five-fold only about 25–30 per cent inhibition is noted. It should also be stated that the ability of streptokinase-activated human plasminogen to dissolve a clot far exceeds the ability of purified plasmin, no matter how the latter is prepared. Trypsin is a poor agent for lysing clot (Table 2). It seems quite likely, therefore, from what has been so far said, that neither plasmin nor trypsin are true fibrinolytic enzymes, although both of these enzymes ultimately can cause clot lysis, by virtue of their proteolytic activity. What I have termed a 'true' fibrinolytic enzyme is one which requires the same

Table 2. EFFECT OF AMINO-CAPROIC ACID ON CLOT LYSIS BY STREPTOKINASE-ACTIVATED HUMAN PLASMINOGEN AND PLASMIN PREPARED BY OTHER METHODS

	No inhibitor	ε-Amino-caproic acid (20 γ)
Streptokinase + human serum	4 min. 10 sec.	7–8 hr.
Plasmin (prepared from streptokinase-activated human serum)	7 min. 45 sec.	40–45 min.
Plasmin (prepared from chloroform-activated bovine serum)	14–15 min.	28–34 min.
Plasmin (prepared from trypsin-activated bovine plasminogen)	14–16 min.	25–30 min.
Trypsin	11–12 min.	15–16 min.

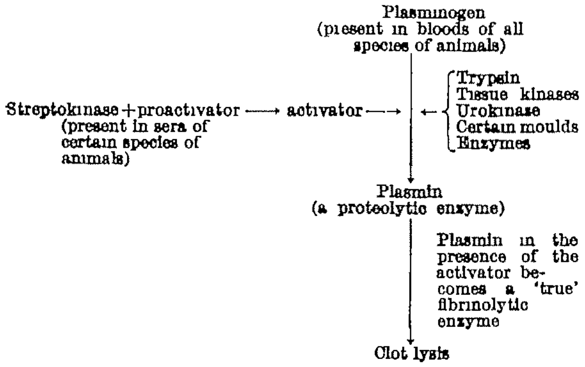

Fig. 1. General mechanism of clot lysis

time for complete dissolution of a fibrin clot and rendering fibrinogen unclottable by thrombin.

What then is the naturally occurring or 'true' fibrinolytic enzyme ? Perhaps there is none. At least a single 'true' fibrinolytic enzyme is not known to-day. Plasmin, once thought to be the enzyme, does not, in fact, occur in the circulating blood. Its inactive precursor plasminogen, present in blood, is transformed to plasmin by an activator, which in turn is formed by an interaction of streptokinase with a proactivator found in the sera of certain species of animals (Fig. 1). Human blood contains this proactivator. It should be noted, however, that some investigators believe proactivator and plasminogen are not identical. Many mould extracts have been reported to be able to dissolve fibrin clot, but it was found by Grey and Sarkar[7] that these extracts dissolve a clot only by virtue of their tryptic activity. Thus it seems that no single substance (enzyme) qualifies at the present time as a 'true' fibrinolytic enzyme. Possibly plasmin, in the presence of the activator, acquires the property of a 'true fibrinolytic enzyme'. The reaction between streptokinase and human plasminogen proceeds with such extreme rapidity that as a rule there is little or no free streptokinase available in the system. This seems to exclude the possibility that streptokinase itself is involved in inducing fibrinolytic activity in plasmin. Whether or not the hypothetical activator of plasminogen itself is causing clot lysis, we do not know; although it looks as though it is the case. Recently, F. B. Ablondi and J. Hagan (personal communication) also expressed such a view.

Recently, Johnson *et al.*[8] demonstrated the inability of plasmin present in the circulating blood to dissolve an artificially formed intravascular blood clot. It was possible, however, to cause dissolution of the clot by introducing further quantities of streptokinase in the blood stream. Thus it appears from these experiments *in vivo* that it is not plasmin alone which dissolves the clot, but rather plasmin in presence of the activator (streptokinase + plasminogen) which does this.

In our attempt to define a 'true' fibrinolytic enzyme, we have mentioned that the ability of such an enzyme to dissolve a clot (clot lysis) and to render fibrinogen unclottable by thrombin should be nearly the same. Trypsin, as reported by Sarkar and Devi[3], needs a much longer time (20 times) to dissolve the clot than it requires to bring about fibrinogenolysis, whereas streptokinase-activated human plasminogen takes the same length of time for both fibrinolysis and fibrinogenolysis (Table 3). Reasons for the difference in the behaviour of these two different types of enzymes should be looked for in the mode of their actions. Enzymes like trypsin dissolve a clot by extensively degrading the protein fibrin. Trypsin also extensively degrades other proteins like denatured hæmoglobin, etc. The method for measuring proteolytic activity of an enzyme depends upon how extensively the enzyme has degraded the protein. In the case of streptokinase-activated human plasminogen it is probable that certain specific linkages holding the fibrin monomers together (to form the gel) are split. This explains why streptokinase-activated human plasminogen is equally active in causing clot lysis and in rendering fibrinogen unclottable by thrombin; whether or not this hypothesis is true is now under further investigation.

Table 3. THE ABILITY OF STREPTOKINASE-ACTIVATED HUMAN SERUM, PURIFIED PLASMINS AND TRYPSIN TO DISSOLVE A CLOT AND RENDER FIBRINOGEN UNCLOTTABLE BY THROMBIN

	Time required for:	
	Fribrinolysis	Fibrinogenolysis
Streptokinase + human serum	4 min. 10 sec.	4 min 30 sec.
Plasmin (prepared from trypsin-activated bovine plasminogen)	14–16 min.	4–5 min.
Trypsin (25 γ)	11–12 min.	30–35 sec.

The work was carried out at the Institute of Laboratories, Boston, Mass., and financed by the Research Division of Jhonson and Jhonson, New Jersey.

A preliminary report of this work appeared in the Proceedings of the Seventh International Congress of Hæmatology held in London, Sept. 7–12, 1959.

Lack of Hæmoglobin in a Fish

IN the toad, *Xenopus laevis* Daudin, two specimens have been described completely lacking hæmoglobin[1,2]. I have been able myself to study a teleost fish without hæmoglobin, namely, an adult male of the cichlid *Cichlasoma severum* (Heckel).

The fish, which measured 72 mm. in length, had lived for about two years in a large tank (25 ± 1° C.), was less active than other cichlids of the same litter and during the last few months mostly moved in the surface of the water layer. In this period only little food was taken. The animal became much emaciated, its response to external stimuli almost ceased and ultimately it was killed by decapitation. The animal was smaller than the fishes of the same brood, of which the length varied from 109 to 154 mm.

At autopsy the blood vessels appeared to be white or perfectly colourless except for the chromatophores in their walls. The heart was pale cream and the liver grey. The gills and the kidneys were cream. The gall bladder was enlarged and contained a large quantity of dark green bile pigment. The spleen was enlarged and coloured light brown. The examination of the blood smears showed that hæmoglobin was not identifiable. Erythrocytes were present, however.

The histological investigation showed that the structure of the organs was normal.

On the strength of accumulation of dark green bile pigment, which was also stated in the case of Ewer[2], it may be concluded that the extensive destruction of the hæmoglobin had occurred very recently.

Another point of correspondence with the case of Ewer was the enlarged light brown spleen which, unlike the case of De Graaf[1], was not coloured slightly yellowish-white.

According to De Graaf, his animal without hæmoglobin had been in that condition all its life, with the implication that the growth to maturity in natural conditions is possible without the presence of hæmoglobin. Ewer, however, arrived at a different interpretation, namely, that the total anæmic condition is a pathological state, which may originate after the adult has become mature. My case, in which also the hæmoglobin destruction had only just been completed, is an argument for Ewer's concept.

Survival without hæmoglobin is distinctly possible, which, however, by no means implies that an animal without hæmoglobin can be as active as a normal one. In my specimen the latter state could be clearly distinguished.

According to De Graaf, normal *Xenopus laevis* are capable of functional elimination of at least 80 per cent of their hæmoglobin by carbon monoxide treatment.

Activation of Plasminogen by Staphylokinase

SOME animal plasminogens, which are unaffected by streptokinase alone, are activated by streptokinase and human globulin. Müllertz[1] has postulated the existence of a proactivator in human serum. Staphylokinase, without human globulin, activates a wider range of animal plasminogens[2] and may, therefore, not require proactivator.

Staphylokinase was prepared from the supernatants of fibrinolytic strains of *Staphylococci* shaken for 7 hr. The supernatant was heated at 75° C. for 30 min. Some inert protein was precipitated at *p*H 3·3. After dialysis, staphylokinase was precipitated at *p*H 4·2.

Euglobulin, in the original serum volume, was used as a source of animal plasminogen. Human plasminogen, prepared by the Kline procedure[3], provided proactivator. Plasmin was assayed by the caseinolytic method described by Norman[4], perchloric acid being used instead of trichloracetic acid.

0·2–0·3 ml. of euglobulin was incubated with up to 400 units streptokinase ('Dornokinase', Burroughs Wellcome and Co.) or an equivalent amount of staphylokinase (assayed against human plasminogen), and with or without 3×10^{-3} units human plasminogen. Maximal activity was obtained after 5–10 min. with 20–140 units kinase. Bovine euglobulin did not inhibit the activation of human plasminogen by staphylokinase.

Table 1

	Human	Guinea pig	Rabbit	Bovine
Streptokinase	+	−	−	−
Streptokinase + Proactivator	+	+	+	+
Staphylokinase	+	+	+	−
Staphylokinase + Proactivator	+	+	+	−
Plasminogen (units $\times 10^{-3}$ per ml. serum)	40	57	34	28

The results, which are shown in Table 1, indicate that staphylokinase does not act through proactivator.

A detailed report of this work is being prepared.

PLANT PHYSIOLOGY

Abnormal Growth and Development in Pea resulting from Exposure to Adverse Conditions during Germination

Kidd and West[1] showed that the amount of growth made by a plant could be determined by the conditions to which the germinating seed was exposed. In their investigations they measured the yield obtained from plants grown from seed soaked in water for varying lengths of time, and they found that in most cases of extended soaking, though the seed germinated more rapidly than seed planted directly in moist soil, the yield obtained from such seedlings was reduced. Their observations of 'physiological predetermination' have been carried further by examining the effect of soaking peas (*Pisum sativum* L.) in water. With this species when seeds are soaked in water for 48 hr. the seedlings that eventually develop may be abnormal (Fig. 1). Normally a small number of seeds, 200, is soaked in a large volume, 500 ml., of tap water kept at 20° C. in darkness. The depth of water covering the seeds was 15 cm., and

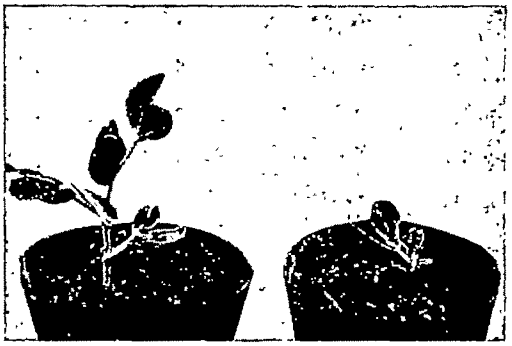

Fig. 1. The plant on the right is a seedling grown from seeds soaked in water for 48 hr. before planting. That on the left is the control planted directly in moist soil

the soaking can best be done in 500-ml. Erlenmeyer flasks.

The effects observed may be related to one or more of the following conditions ; (*a*) A disturbance of the normal metabolism during the first 48 hr. of germination and the maintenance of this abnormal condition during the first stages in development. (*b*) The removal by leaching of an essential water-soluble metabolite. (*c*) The accumulation within the seed of a material which adversely affects growth.

It was thought that peas soaked in stagnant water would respire anaerobically, and therefore it was decided to compare the response of soaked seed with seed which were exposed during the first 48 hr. of germination to an atmosphere containing 20 per cent carbon monoxide. The seeds which were exposed to this atmosphere were kept in darkness, at 20° C., during the period of exposure. In these seeds normal respiration would be blocked since the cytochrome system would be inoperative in this atmosphere. To determine if metabolites were lost, or substances accumulated during soaking, a third sample was kept in running tap-water for 48 hr. At the start of the experiment a fourth sample was planted directly in moist soil in an unheated greenhouse. At the end of treatment the other three samples were sown out in the same bed. After 23 days the plants were harvested, and measurements made immediately on a sample of 30 plants from each treatment (Tables 1 and 2). The number of nodes formed by the largest bud of the first and second nodes (in pea there are usually more than one axillary bud at each node) and the condition of the terminal bud were recorded. If flower primordia were present the number of these was noted, but only when the primordium had recognizable flower parts present ; if no flower buds were present the apex was scored as alive and active, or dead. The remainder of the seedlings produced were stored in 70 per cent alcohol, and from them was obtained the length of the largest axillary bud at the first and second node, and the length of the largest flower present. Gross abnormalities were treated separately. In the batch planted directly into moist soil 161 seedlings were present at harvest and of them 7 were grossly abnormal, while seeds which had been exposed to carbon monoxide produced 171 seedlings with 9 abnormal. Those seeds which were exposed to water produced respectively 129 and 175 seedlings with 34 and 5 abnormals for those soaked in stagnant and running water. The most common type of aberration encountered is suppression of the terminal bud and development of the basal axillary buds. Leaf shape is affected and treated plants are usually slightly chlorotic.

The findings are recorded in Tables 1 and 2.

The results indicate that the normal course of development in pea can be altered by exposing the seed during germination to conditions which affect aerobic respiration. This effect is seen as the removal of apical dominance, in extreme cases by the death of the terminal bud. It appears that the tissues most affected by the treatment are the meristems present in the embryo.

Table 1

	No. of plants with apical buds			Total No. of formed flowers	Average No. of nodes	
	Flowering	Veg.	Dead		Bud No. 1	Bud No. 2
Moist soil	28	1	1	75	2·86	3·76
Running water	28	1	1	49	1·30	3·23
Stagnant water	18	4	8	0	3·50	4·42
20 per cent carbon monoxide	25	1	4	40	1·83	3·24

Table 2

	No. of plants	Average length (relative to moist soil = 100)					
		Bud No. 1		Bud No. 2		Largest flower	
Moist soil	131	5·4	100	9·1	100	5·6	100
Running water	145	5·7	105	9·7	106	5·0	89
Stagnant water	99	6·6	122	11·2	124	3·0	54
20 per cent carbon monoxide	141	6·0	111	9·8	108	2·8	50

This work is being continued to determine the nature of the changes which take place in seeds germinating under the conditions described.

Nitrate Content of Herbage at Different Manurial Levels

Following on the results reported in *Nature*[1], nitrate nitrogen determinations have recently been made on herbage samples provided by Dr. Rice Williams, of the National Agricultural Advisory Service, from an experiment where sulphate of ammonia had been used at six levels, 0, 2, 4, 6, 8 and 12 cwt. per acre, to swards consisting of a number of different grass mixtures[2]. Nitrogen was applied in mid-April and the herbage was cut six weeks later. The results from one of these mixtures (mixture *B*) are illustrated in Fig. 1. Mixture *B* was seeded down with Italian ryegrass, perennial ryegrass *S*.101, timothy *S*.48, cocksfoot *S*.26, *S*.143, *S*.37 and Danish, red clover *S*.123, alsike, white clover *S*.100 and *S*.184. The experiment was in the form of a randomized block, each level of application having three replicates.

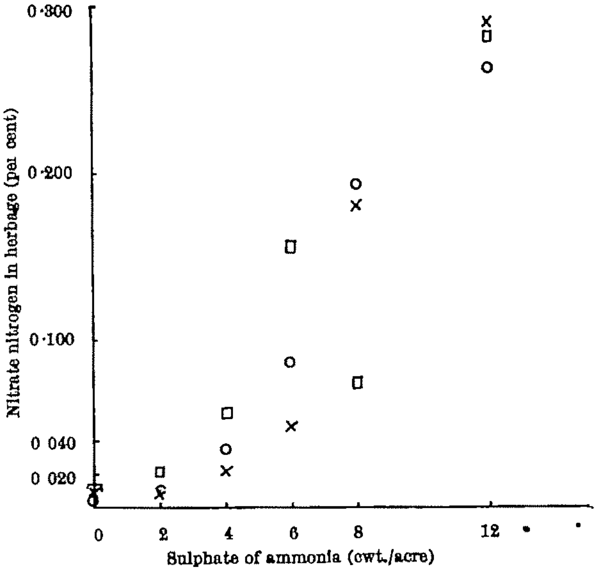

Fig. 1. Relation between levels of nitrogen application and of nitrate nitrogen in herbage. O, ⊡, ×, replications of each treatment

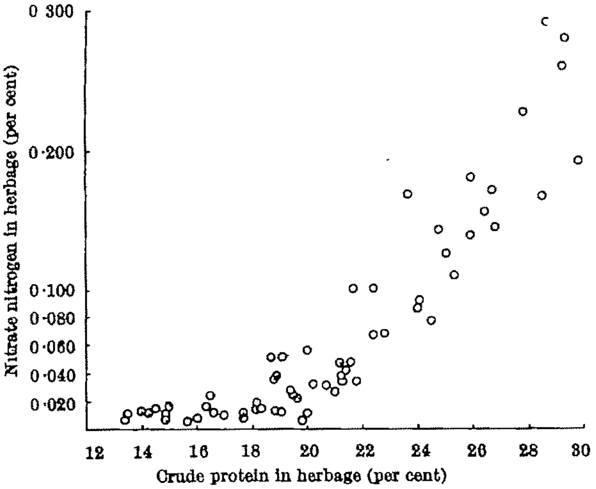

Fig. 2. Relation between percentage crude protein and nitrate nitrogen in herbage

It is seen that nitrogen, applied in the ammonium form, and with a normal interval between application and cutting, has resulted in accumulations of nitrate nitrogen detectable at the 4-cwt. level and considerable at the 8- and 12-cwt. levels.

In Fig. 2, nitrate nitrogen is plotted against crude protein; results from two other grass mixtures in the same experiment are also included. I am indebted to Dr. Rice Williams for the crude protein data.

In amounts greater than 0·07 per cent of the dry matter, expressed as nitrogen, nitrate is reported to be toxic to the animal[3], and amounts greater than 0·22 per cent are reported to be lethal[4]. In the present experiment a crude protein content greater than about 22 per cent would render the material suspect for feeding purposes.

Full details of this investigation are being prepared for publication and will appear elsewhere in due course.

Influence of Hydrogen Ion Concentration and Autoclaving on Gibberellin

In at least two reports the method of sterilization for medium to be used for tissue culture experiments was autoclaving[1,2]. The question of the heat stability of gibberellin is raised. It is generally thought that gibberellin is stable on the basic side of neutrality and at room temperature at neutral or near neutral *p*H, and more labile at elevated temperatures at extreme *p*H values. It has been stated that even weakly acid media will destroy gibberellin and that it is much more stable in neutral and basic solutions (Stowe, B. B., private communication, November 7, 1958).

Several investigators have recently been interested in the heat stability of gibberellin in culture media in the *p*H range 5–6. Experiments have generally been conducted with gibberellin by the sterile-filtration technique. The need for this technique and validity of autoclaving with the medium have been investigated.

Treatments were carried out with autoclaved and unautoclaved stock solutions of gibberellin (supplied by Chas. Pfizer and Co., and consists of gibberellin A and gibberellin X, gibberellic acid) at 100 μgm. per ml. The solutions were buffered to maintain a stable *p*H during autoclaving and treatment of the plants. The buffers at *p*H 1·0 and 3·5 were phthalate–hydrochloride mixtures; *p*H 6·0 was a phthalate–sodium hydroxide mixture; *p*H 10·0 was a boric acid–potassium chloride–sodium hydroxide mixture[3]. Autoclaving was at 20 lb./sq. in. for 15 min.

In all cases the solutions were cooled after autoclaving and placed in the refrigerator for storage before and after use on the plants. During the total length of the experiments (January 17 to December 5, 1959) new stock solutions were made up and new sets of solutions autoclaved for use on the test plants. The solutions, which were re-adjusted to *p*H 6·0, were first autoclaved at the indicated *p*H values and after cooling were adjusted with hydrochloric acid or sodium hydroxide to a *p*H of 6·0 before treatment (0·05 c.c. of the solution) of the plant.

These experiments were set up using the Phinney[4] test for dwarf-1 mutant corn. The plants were treated one week after germination. The dosage was 5γ (0·05 c.c. of 100 γ/ml.) per plant treated only once, at the beginning of the experiment. Recorded readings were taken on the plants two weeks after treatment.

To test whether the *p*H or buffer solutions alone had any effect on growth, the dwarf mutants received likewise 0·05 c.c. of the respective buffer solutions. Measurements of the second internode only were taken at the end of two weeks from treatment. Three plants were used in each pot for each treatment. Results were taken from four to five separate experiments over a 4-month period.

From Table 1, the following observations can be made: (1) all autoclaved solutions possessed less activity than those unautoclaved: (2) the highest activity was from solutions buffered at *p*H values of 6·0 and 3·5, for all treatments, with very little difference between the two; (3) the least activity was from solutions at *p*H 1·0 for all treatments; (4) activity for *p*H 10·0 was intermediate between that at *p*H 3·5 and 6·0, and 1·0; (5) plants treated with buffer alone showed no stimulation whatsoever, being

Table 1. TREATMENT OF DWARF-1 MUTANT CORN SEEDLING, WITH 5 μGM. OF GIBBERELLIN AT VARIOUS BUFFERED *p*H VALUES, AFTER AUTOCLAVING OR NOT AUTOCLAVING

Measurement of the second internode in centimetres after two weeks treatment; numbers in brackets are number of plants included to calculate average

Treatment	*p*H of buffer			
	1·0	3·5	6·0	10·0
Unautoclaved	2·5±1·2* (12)	6·8±2·0 (15)	6·6±1·4 (12)	5·2±1·4 (11)
Autoclaved	1·3±0·4 (10)	4·6±1·5 (14)	4·9±1·8 (12)	3·3±1·1 (12)
Autoclaved, readjusted to *p*H 6·0 after autoclaving	1·8±0·6 (10)	4·6±0·9 (13)	4·5±1·3 (15)	3·3±1·4 (11)
*p*H control	1·0 (3)	1·2 (3)	1·5 (3)	1·0 (2)
Normals	5·5±2·3 (22)			
Dwarf controls	1·2±0·4 (12)			

* Standard error of the mean

the same as the dwarf controls; (6) solutions initially autoclaved in the various buffers and afterwards adjusted to a common *p*H of 6·0 were uninfluenced by this post-autoclaving treatment; (7) all gibberellin solutions, regardless of type of treatment, showed greater activity than solutions containing no gibberellin (*p*H control plants), and caused greater growth of the dwarfs than the untreated (dwarf) controls; (8) the unautoclaved gibberellin solutions at *p*H 3·5 and 6·0 showed greater activity than the normal, non-dwarf plants; (9) the reduction in activity of gibberellin due to autoclaving was in no case greater than 50 per cent (for *p*H 1·0) and for solutions at *p*H 3·5 and 6·0 it was roughly 33 and 25 per cent, respectively.

From these observations one may draw the following conclusions: (1) There is significant (statistical) loss of activity caused by autoclaving of gibberellin, but this loss is not so significant biologically (see explanation below); (2) the loss of activity is between one-third and one-fourth of the original activity at the optimum *p*H value for most culture solutions employing gibberellin, especially sterile tissue culture; (3) based on the experiments with *p*H controls and the re-adjusted autoclaved solutions, the *p*H factor itself does not influence these plant responses directly; the effect of heat and *p*H is rather on the gibberellin molecule itself, and subsequent influence of the latter on plant response.

The general over-all conclusion is that the autoclaving of gibberellin at the normal *p*H of culture media is not biologically significantly detrimental or destructive to the gibberellin content in the medium. From standard curves of biological activity, as well as response in plant tissue culture, the loss of as little as one-third to one-fourth, or even more, of the activity of gibberellin at any single concentration is never very significant, since most experiments employ the logarithm of the concentration of growth factors instead of linear units. Autoclaving of other organic growth factors and auxins, especially indoleacetic acid, would show approximately similar losses. Therefore, it is generally safe to use the autoclaving technique in the usual experiments employing gibberellin in plant tissue culture, especially where the amounts employed are greater than 1 p.p.m.

Since these conclusions are based on one of the only reliable methods for the assay of gibberellin at present—the bioassay technique, limited to the assay with Dwarf-1 mutant corn in this instance—it is not possible to speculate what the active compound(s) is (are). It is specifically adapted to each bioassay test. Further work, both biological and chemical, is required to identify the active principle.

I wish to thank Chas. Pfizer and Co., Inc., for supplying the gibberellin, and the National Science Foundation for supporting the investigation. Mr. Clarence Saulsberry assisted in the experimental work; Dr. B. O. Phinney supplied the Dwarf-1 mutant seeds.

RADIOBIOLOGY

Effectiveness of Dietary Substances in reducing the Retention of Chronically Ingested Radiostrontium; Studies with Tannin

THERE has been considerable interest in the testing of substances that may reduce the body burden of chronically ingested radiostrontium. The present work, using tannin as an example, emphasizes the caution that must be used in the interpretation of single-dose studies, and also describes a relatively short-term procedure which appears to be practical.

In a recent report, Ukai *et al.*[1] have shown that the skeletal retention of a single dose of strontium-90 could be reduced if followed immediately by the oral administration of a 1 or 2 per cent tannin solution. It has been suggested from these results that consumers of tannin (in tea) would absorb and retain less fall-out strontium-90 than otherwise. Such interpretations of data from single-dose studies applied to situations of normal strontium-90 ingestion can be especially misleading. First, strontium-90 is ingested continuously as a contaminant in most food products; secondly, strontium-90 is consumed simultaneously with dietary calcium and other constituents of the diet. Under these conditions, a complexing agent may yield an entirely different effect from that when it is given as a single dose with carrier-free radiostrontium. In fact, our previous experience has shown that substances which complex or chelate strontium and calcium, for example, citrate, phytate, sodium ethylenediaminetetraacetate, were without effect in reducing the body burden of continuously ingested radiostrontium[2]. In view of this prior knowledge, it was felt necessary to determine the influence of tannin on radiostrontium and radiocalcium retention in the situation where (*a*) the radiostrontium is continuously ingested over a period of days, (*b*) the tannin is consumed over the same time period, and (*c*) the normal constituents of the diet are also present.

Twenty-four rats were divided into four groups of six rats each and placed in individual cages. Drinking-water labelled with essentially carrier-free calcium-45 and strontium-85 was made available in graduated drinking tubes; the levels of calcium-45 and strontium-85 were 0·1 and 0·01 μc. per ml., respectively. At the same time, the rats were given a complete semi-synthetic diet containing either 0, 1, 2 or 4 per cent tannin (Nutritional Biochemicals, Inc.); the level of calcium in these diets was about 0·48 per cent. The rats were allowed to ingest the 'spiked' water and diet *ad libitum* over an experimental period of ten days. The amount of water and diet consumed was measured. At ten days, the rats were killed and retention of calcium-45 and strontium-85 in the femur was determined by usual radioassay procedures. The results are given as 'per cent of total ingested activity'. It should be pointed out that previous studies have shown that radiostrontium and radiocalcium ingested continuously in drinking water equilibrate with, and act similarly to, these elements ingested in the diet[3].

The results are presented in Table 1. It may be seen that the presence of tannin in the diet at the higher levels appreciably decreased the growth-rate of the experimental animals although feed consump-

Table 1. INFLUENCE OF TANNIN ON THE FEMUR RETENTION OF CONTINUOUSLY INGESTED CALCIUM-45 AND STRONTIUM-85

† Values represent mean ± standard error of the mean of six animals per group.

‡ Observed ratio (OR) = ^{85}Sr/^{45}Ca in femur ÷ ^{85}Sr/^{45}Ca in diet.

tion was not reduced. In regard to radionuclide retention, a slight decrease in radiocalcium retention by the rat femur was noted in the tannin groups in contrast to the controls. However, in the presence of 2–4 per cent dietary tannin, the strontium-85 content of the rat femurs was significantly increased, causing an increase of the strontium/calcium observed ratio. An increased strontium/calcium ratio had similarly been observed in rats fed a liquid milk diet containing sodium ethylenediaminetetraacetate. Since tannin and ethylenediaminetetraacetate possess the common property of binding calcium ions to a somewhat greater degree than strontium ions, the present results may possibly be explained as follows. Radiostrontium previously complexed with tannin in the gut could be replaced by stable calcium and, therefore, become available for absorption. Parental tannin would act similarly, that is, releasing complexed strontium-85 when replaced by plasma calcium.

The above results are not in direct conflict with those of Ukai *et al.*[1] because entirely different conditions were employed in the two studies. Any disagreement would be in the extrapolation of single-dose data to the chronic situation in which strontium-90 is ingested with the diet at each meal. When this chronic situation is experimentally simulated as in the present study, it was observed that tannin at various levels in the diet had *no* beneficial effect in reducing the body burden of radiostrontium in the rat. Although single-dose studies of the type referred to may have usefulness in readily assessing the potential value of any test substance, it is recommended that promising compounds should be subjected to a chronic ingestion test before extrapolations are made to the chronic situation. It is further suggested that the influence of the test substance should be simultaneously determined on radiocalcium retention, since interpretations are facilitated and important information of possible effects on an essential nutrient is thereby provided.

This investigation was supported by the U.S. Armed Forces Special Weapons Project through contract *DA*-49-007-*MD*-897 administered by the U.S. Surgeon General, Department of Army.

Early Injury of Chromoexcretion after Total Irradiation of Rats

IT is claimed by all available literature that damage occurs to the function of the liver after whole-body irradiation by doses, approaching *LD*100, from as late as the stage of development of the secondary post-radiation changes[1,2]. Some biochemical results, however, support the opinion that the liver cell should be damaged in its function at the earliest stage of an acute irradiation disturbance[3-5]. To prove the early functional lesion we carried out experiments with bengal rose tagged with radioactive iodine-131.

Experiments were performed on 50 male rats of the Wistar strain averaging 200 gm. in weight. Twenty-six rats were irradiated with a dose of 600 r. by the deep X-ray apparatus of 200 kV., 15 m.amp., filtration 3 mm. aluminium at a distance of 75 cm. and 32 r./min. The remaining 24 rats were used as a control group. Tests were accomplished in 4 groups, of 6 and 8 rats respectively, the controlled and irradiated ones, 2, 6 and 24 hr., and 14 days after the irradiation. At the given intervals we applied to the tail vein of the rats 5 μc. bengal rose–iodine-131 in 1 ml. of isotonic solution[6]. 10 min. after the injection the rats were killed, the liver was taken out and homogenized separately.

Gamma activity of the homogenates was determined by the scintillation method. The activities of the control-group homogenates were taken as 100 per cent and the activities of the irradiated groups were expressed as a percentage of the control-group activity.

In the group tested 2 hr. after the irradiation the uptake value of 81 per cent, as compared with 100 per cent of the control group, was still above the 5 per cent limit of significance. The further group, tested 6 hr. after irradiation, has its uptake lowered to 83 per cent of limit of error below 1 per cent. The group killed 24 hr. after irradiation has its uptake lowered to 76 per cent with 0·5 per cent limit error, and that killed on the fourteenth day after irradiation exhibits lowering to 74 per cent with ·1 per cent significance.

Uptake of bengal rose is a specific property of polygonal liver cells. Radioactive bengal rose permits differentiation of the great damage done to the blood—or bile pole of the liver cell. In preliminary experiments, during investigations for the most suitable moment for homogenization after injection, we ascertained the maximum difference in the tenth minute after the application of colouring matter, that is, at the uptake maximum. This fact is an indication of considerable damage caused to the blood pole of the liver cell. The question of this mechanism is still open, and is the subject of further investigation.

The possibility of distributive volume changes of bengal rose is not likely to make itself felt to any extent in these results. This is due to the fact that distributive volume for bengal rose is practically equal to the plasma volume, and there is no literature known to us suggesting that considerable changes occur in the plasma volume in the early stages after the irradiation of the whole body.

We believe that the significant lowering of uptake maximum in the sixth hour after irradiation explains the early injury to the chromo-excretional function in rats after whole-body irradiation by lethal doses of 600 r. using bengal rose–iodine-131.

BIOLOGY

Thermal Barrier to the Infectivity of *Entamœba invadens* in Snakes

THE optimum temperature for the *in vitro* growth of *Entamœba invadens* has been determined by several investigators to be between 20 and 30° C.[1,2]. I found that the maximum temperature at which *E. invadens* could be grown in developing chicken embryos was 30° C.[3]. The following account represents the results of a preliminary investigation on the ability of *E. invadens* to establish itself in snakes kept at temperatures above normal.

Three adult grass snakes, *Thamnophis sirtalis*, free of parasitic Amœbæ, were used in each of the two experiments. All the snakes were inoculated *per os* with equal doses of a heavy suspension of trophozoites and cysts of the *I.P.*2 strain of *E. invadens*[4], taken from polyxenic cultures.

In the first experiment snakes 1 and 2 were placed in individual jars in a hot room, in which the temperature fluctuated between 34° and 37° C. Snake 3 was kept in the laboratory, the room temperature varying from 20° to 23° C. During the course of the experiment the snakes' fæces were examined for the presence of Amœbæ and of blood, which is an indication of intestinal ulceration produced by the Amœbæ. The snakes' rectal temperature was recorded at the same time by means of a very fine thermometer. Table 1 represents the findings in Exp. 1.

Table 1

	Days after inoculation	Room temperature (deg. C.)	Rectal temperature (deg. C.)	Microscopical examination of fæces
Snake 1	1	35·5	34·5	Negative
	2	37	32	Negative
	4	34	34	R.B.C., no Amœbæ
	5	35·5	34·5	R.B.C., no Amœbæ
	6	35	33·5	No Amœbæ
	7	34·5	34	No Amœbæ
	8	Died. No pathological changes and no Amœbæ seen in internal organs.		
Snake 2	1	35·5	34·5	Negative
	2	37	32	Negative
	4	34	34	R.B.C., no Amœbæ
	5	35·5	34·5	R.B.C., Amœbæ present
	6	35	34·5	Few Amœbæ
	7	34·5	34·5	Few Amœbæ
	8	Died. No pathological changes and no Amœbæ seen in internal organs.		
Snake 3	1	21	20	Negative
	2	22	22	Negative
	4	20	20	Negative
	5	20·5	19·5	Blood and Amœbæ
	6	21·5	21	Blood and Amœbæ
	7	23	25	Blood, no Amœbæ
	8	Killed. Large intestine hæmorrhagic and ulcerated. Amœbæ recovered in cultures made from the intestine and liver.		

Three other snakes were similarly inoculated in the second experiment; Nos. 1 and 2 were placed in separate jars in the hot room and No. 3 was left in the laboratory.

Snake 1 died two days after inoculation. Upon autopsy Amœbæ were not seen in its intestine or liver, but a culture made from the intestinal contents became positive for *E. invadens*.

On the seventh day after inoculation the rectal temperature of snake 2 was 33° C., while that of the room was 34·5° C. There were no living Amœbæ in its fæces on that day, but many cells resembling dead Amœbæ were observed. A sample of fæces was taken from the same snake on the fifteenth day after inoculation, but no Amœbæ were seen in it, nor did the cultures made from the fæces become positive for Amœbæ. Snake 2 was found dead on the seventeenth day after inoculation. There were no pathological changes in its intestine or liver. Cultures made from these organs did not become positive for Amœbæ. It was also noted that the flagellates, which were very numerous in the intestine of this snake at the beginning of the experiment, were all gone when autopsy was performed.

Snake 3, which was kept in the laboratory, developed typical amœbiasis about a week after inoculation and was killed on the tenth day. Its large intestine was heavily ulcerated, and *E. invadens* were seen in the intestine and the liver.

These preliminary experiments have shown that *E. invadens* is unable to establish infections in snakes at high temperatures, although, as seen in snake 2 in Exp. 1 and in snake 1 in Exp. 2, the Amœbæ survived in the intestine for a few days. It is also interesting that the flagellates, often present in snakes' intestines, apparently could not survive at high temperatures. The snakes kept at high temperatures died within relatively short periods of time, although their death was not due to the amœbic infection.

It is planned to repeat these experiments, using strains of *E. invadens* which have been adapted to *in vitro* growth at 35° C.

This work was done at the National Institute for Medical Research, London, N.W.7, during the tenure of a Donner post-doctoral fellowship.

Variations in the Plasma-Level of Chloride in Hatchery-reared Yearling Atlantic Salmon during Parr–Smolt Transformation and following Transfer into Sea-Water

The successful adaptation of juvenile Atlantic salmon to sea-water requires a prior physiological 'metamorphosis'—parr–smolt transformation[1]. The occurrence of this change appears to depend in part upon age, and in part upon the complex of factors controlling the growth-rate of the parr[2]. In addition to external evidences of parr–smolt transformation such as loss of parr marks, decrease in condition factor and deposition of guanine there must also be some variation in biochemical systems associated with the regulation of body electrolyte-levels relative to those of the environment. Evidence for such changes may be seen in the changing plasma chloride-levels of two migratory salmonids, *Oncorhynchus masou* and *Salmo gairdneri*, during transition from parr to smolt stages[3]. Several investigators have also reported marked development of Keys–Willmer cells, units thought to have an ion secretory role, in a number of species of salmon prior to downstream migration[4]. Fontaine, however, could find no significant variation in blood chloride-levels of smolting Atlantic salmon, although a decrease did occur in tissue concentration[5].

During the course of an investigation of factors influencing the adaptability of hatchery-reared yearling Atlantic salmon to sea-water it was possible to observe plasma chloride-levels in fish maintained in freshwater over a five-month period. The animals were obtained from the Grand Lake Fish Culture Station, Nova Scotia, and were held in recirculating aquaria at 11° C. in the laboratory. Analysis of chloride content was carried out by the mercurimetric titration procedure on 50 and 100 lambda-plasma samples. Samples were obtained by exposed cardiac puncture from anæsthetized animals.

Fig. 1 summarizes results obtained on the 45 animals sampled. These were assessed at the time of sampling as parr (parr marks distinct, no silvering), silvery parr (parr marks more or less distinct, some silvering) or smolt (parr marks absent, marked silvering). In small parr (6–15 gm.) chloride-levels were relatively size-stable and ranged from 125 to 139 m*M*/l. In somewhat larger parr (15–26 gm.) plasma chloride decreased markedly with increase in weight. In silvery parr (17–31 gm.), on the other hand, chloride concentrations increased with increases in weight to a maximum of 145–150 m*M*/l. A slight decrease from this level was observed in the smallest smolt sampled, but values for larger animals were relatively constant at between 130 and 140 m*M*/l.

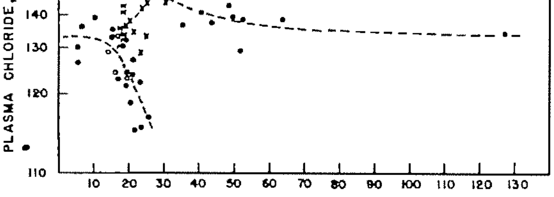

Fig. 1. Variation in plasma chloride concentration with weight and stage of development in freshwater-adapted Atlantic salmon

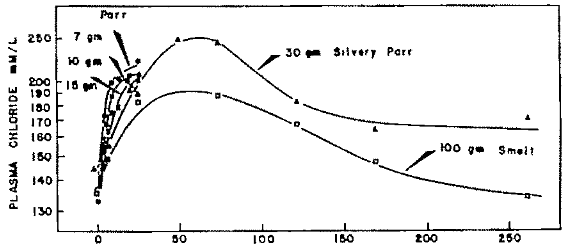

Fig. 2. Plasma chloride concentrations of parr (7, 10, 15 gm.), silvery parr (30 gm.) and smolt (100 gm.) following transfer from freshwater into sea-water (chloride concentration: 400–410 m*M*/l.)

From the observations it is inferred that the initiation of parr–smolt transformation is accompanied by alterations in the electrolyte metabolism of the parr which lead to a loss in regulatory ability. Salt balance in freshwater fishes involves the precise adjustment of uptake processes (dietary gain, active absorption) with processes leading to loss or dilution (urinary output, outward diffusion). A predominance of the latter group of factors is indicated in late parr, while a reversal of this effect is apparent in silvery parr. The results suggest, as well, that the process of smoltification may be well under way before any obvious indications of its occurrence are present, since chloride imbalance was present in parr displaying distinct parr marks and the absence of any silvering.

Variation in patterns of endocrine activity may account for the distinct decrease in regulatory efficiency which is apparent in the early stages of parr–smolt transformation. Data assembled by Pickford and Atz and by Hoar[6] suggest that increased pituitary, thyroid and adrenal cortical activity accompany smoltification. Of particular interest are the demonstrations by Hoar[4] of a relationship between thyrotropic hormone and the development of Keys–Willmer cells in Atlantic salmon parr, and by Fontaine and Hatey[7] of marked increases in the blood-levels of 17-hydroxycorticosteroids in the smolt stages of the same species.

Chloride-levels of fish transferred from freshwater directly into sea-water (400–410 m*M*/l.) are recorded in Fig. 2. Values were interpolated from regression equations relating plasma chloride to body-weight in groups of 15–20 fish.

Small parr (7, 10, 15 gm.) took up chloride rapidly and none survived for longer than 26 hr. Smaller parr took up chloride more rapidly than did larger animals, and died earlier. This observation is consistent with those made earlier by Huntsman and Hoar[1] on the same species.

Animals in the process of transformation appeared to be developing the capacity to become adapted to sea-water. Increases in chloride-level were, however, more marked than those observed in smolt, and the silvery parr required a longer time to return to freshwater chloride-levels than did completely transformed fish. The process of adaptation to sea-water required about ten days in fully transformed smolt.

In general, this study tends to support the conclusions of Koch, Evans and Bergstrom[8] based upon sodium regulation in Atlantic salmon parr and smolt. A loss of regulatory capacity occurs while the fish become transformed from the freshwater-adapted parr stage to the potentially marine smolt stage, while adaptation to sea-water appears to be dependent upon both size and stage.

It is a pleasure to acknowledge the financial support of this project by the National Research Council of Canada and the Nova Scotia Research Foundation. A full report of the study will be published elsewhere.

Study of Life-cycle of *Schizosaccharomyces octosporus* by means of Ultra-thin Sectioning and Electron Microscopy

CYTOLOGICAL studies of the yeast of the genus *Schizosaccharomyces* have been few and limited primarily to observations by means of light microscopy[1-3]. Although these studies reveal the nature of some of the general cytological changes which occur during various phases of the life-cycle of these yeasts, detailed studies are lacking. Some of the conflicting views and limited observations of these investigators may be attributed at least in part to the resolution limit of the light microscope. A study of the nature and sequence of the cytological changes which occur during cell division, conjugation, ascosporogenesis, and germination was therefore carried out by means of ultra-thin sectioning and electron microscopy in order to obtain a more detailed and accurate description of the cytological changes which occur. Various cytochemical methods were also employed in order to correlate structures observed in electron micrographs with structures observable with the light microscope. *Schizosaccharomyces octosporus*, N.R.R L. Y-854, obtained from Dr. L. J. Wickerham, was selected for study. The techniques used for specimen preparation have been described previously[4].

Fig. 1,*a–i* illustrate the nature and sequence of the cytological changes accompanying cell division. It was observed that karyokinesis occurs well in advance of cytokinesis and that transverse cell-wall formation occurs by the annular centripetal growth of an inner lateral portion of the cell wall. The cytoplasmic membrane appears to remain in close proximity to the cell wall during cytokinesis. After formation the transverse cell wall increases in thickness and electron-dense membrane-like structures are formed. The transverse wall then splits as shown, the transverse membranes serving initially as the outer portion of the cell wall. These membranes may be analogous to the splitting plate observed in dividing cells of *Histoplasma*[5]. Nuclear division appears to occur by a process of elongation and constriction, further observation of chromatin behaviour being beyond the scope of the techniques employed. The nuclear membrane appears to remain intact throughout all the observed stages of nuclear and cytoplasmic division.

The conjugation process (Fig. 1,*j–o*) appears to be initiated by the attachment of cells in pairs by a portion of the cell wall. The central portion of the connecting wall disintegrates, thereby forming a short, narrow conjugation canal which afterwards increases both in length and width. During this stage the nuclei migrate toward one another and fuse within the canal. The nuclear membrane remains intact except in the region of nuclear fusion. Vacuoles are formed in the majority of cells during or immediately after fusion nucleus formation. The fusion nucleus (presumably diploid) then undergoes a series of divisions resulting in the formation of haploid nuclei (Fig. 1,*p–u*).

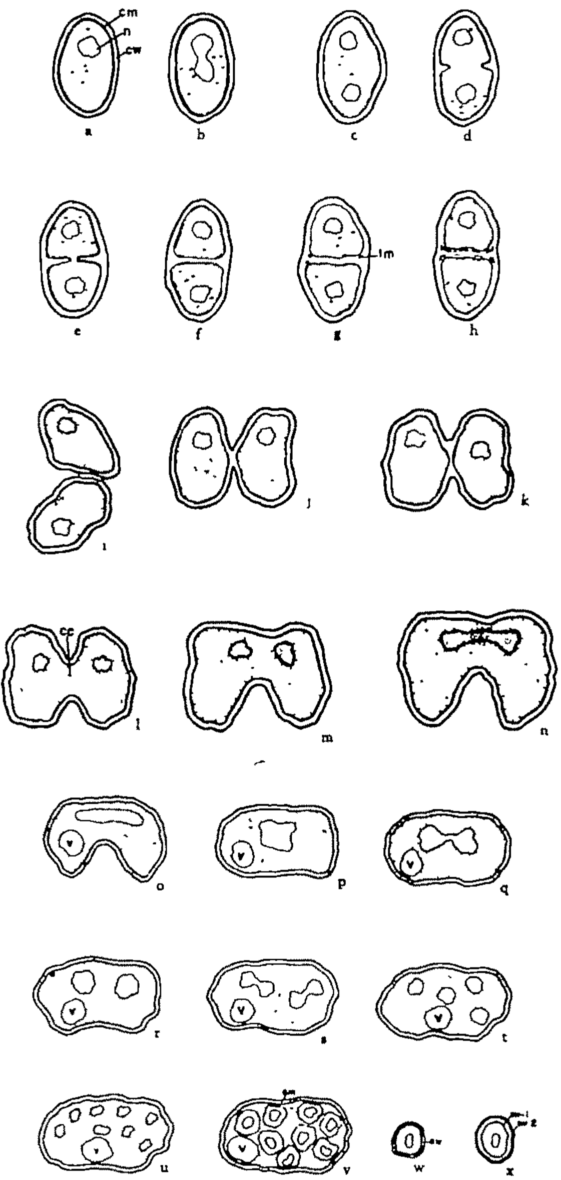

Fig. 1. Life-cycle of *S. octosporus*. *a–i*, Cell division; *j–v*, conjugation, nuclear division and sporulation; *w*, developing ascospore; *x*, appearance of a mature ascospore prior to germination. *AM*, Ascospore membrane; *AW*, ascospore wall; *CC*, conjugation canal; *CM*, cell membrane; *CW*, cell wall; *N*, nucleus; *SW*-1, inner, non-electron dense portion of the ascospore wall; *SW*-2, outer, electron-dense portion of the ascospore wall; *TM*, transverse membrane; *V*, vacuole

Sporulation (Fig. 1,*v*) is initiated by the formation of a double ascospore membrane around each nucleus. The inner portion of the ascospore membrane serves as the structural precursor of the cytoplasmic membrane. The ascospore wall then develops around the outer portion of the ascospore membrane (Fig. 1,*w*). Mature and germinating ascospores are surrounded by two spore coats (Fig. 1,*x*), the inner one giving rise to the vegetative cell wall during germination. Germination is initiated by swelling and elongation of the ascospores with subsequent disruption of the outer spore coat. Vegetative cell division is then initiated.

The results of this study generally support and extend considerably the previous observations on cell division, sporulation, and germination in *S. octosporus*[1-3]. The electron micrographs from which the illustrations are drawn, and a more detailed description of the results will be presented elsewhere.

BACTERIOLOGY

Antigens of *Azotobacter*

Previous attempts at studying the antigens of *Azotobacter* have met with only limited success. Azo and Yoshida in a brief report[1] described complement-fixation by *Azotobacter* cells in the presence of specific antisera but gave few experimental details. Jensen and Petersen[2] obtained an agglutinating antiserum for *Azotobacter chroococcum*. Recently, Petersen[3] studied the agglutinogens of *Az. chroococcum*, *Az. vinelandii* and *Az. agilis*. *Az. chroococcum* and *Az. vinelandii* had antigens in common and showed serological affinities to *Beijerinckia* sp. *Az. agilis* appeared to be antigenically distinct Eisenstark *et al.*[4], on the other hand, using apparently adequate technical methods, failed to produce antisera to *Az. agilis* or "numerous other azotobacter species". Heidelberger (quoted in Lawson and Stacey[5]) showed *Az. chroococcum* polysaccharide to be antigenic.

A knowledge of the antigenic structure of *Azotobacter* could be of value in two ways: the genus presents taxonomic problems which may be clarified by a serological study[3] and the large cells are eminently suitable subjects with which to study the distribution of antigens within the cells. Methods are available for the fractionation of these organisms into their structural components[6]

In the present investigation cultures were grown on glucose, nitrogen-free, agar at 30° for two days and harvested into sterile saline. Antisera to *Az. agilis* (V J.) were prepared by injecting freshly prepared untreated cell suspensions, adjusted to an opacity equal to that of Brown's tube No. 8, intravenously into rabbits. A series of injections consisting of 0·5, 1·0, 2 0, 2·0, 2 0 and 2·0 ml. at 3-day intervals was followed by a rest period of 1 month, after which three further injections of 1·0, 2 0 and 2 0 ml. were given. Antisera were stored without preservative at −20°.

Table 1. Distribution of *Azotobacter agilis* Antigens among Other *Azotobacter* Species

Species (strain)	No of antigens detected	Known antigens (referred to a standard gel diffusion plate—antigen/antibody lines numbered from the antiserum reservoir outwards)				
Az. agilis (V J.)	5	1	2	3	4	5 (complex)
Az. agilis (4 4)	5	1	2		4	5 (partial)
Az. insigne (V.J.5)	4		2		4	
Az. macrocytogenes (0)	4		2		4	
Az. chroococcum (222)	1				4	
Az. beijerinckii (L.H 1)	2				4	
Az. vinelandii (0)	3				4	

Antigen–antibody reactions were studied by the Ouchterlony gel diffusion technique. Cells from 2-day old agar cultures were harvested into sterile saline containing 1 in 10,000 thiomersalate and deposited by centrifuging. The deposit was resuspended in a minimal amount of the same medium to give a thick paste of cells which could just be handled conveniently with a Pasteur pipette. The resulting cell suspensions were used as antigen preparations. Sensitivity and resolution of lines were improved by using thin layers of diffusion medium, and after several trials 0·5 ml. amounts of a 1·7 per cent agar/saline base containing 1 in 10,000 thiomersalate in 3½-in. Petri dishes were chosen as the conditions giving the best results. Antigen suspensions and antisera were accommodated in cork-borer holes, and the Petri dishes were sealed into small plastic bags and incubated at 30°. Although precipitation lines could be seen after 24 hr., the full complement of lines required up to two weeks to develop—presumably some antigens are only slowly released from the cells under these conditions. Fully developed plates were preserved by drying, stained with naphthalene black, and photographed against a yellow safelight screen.

Fig. 1 shows a typical result obtained by allowing antigens from six species of *Azotobacter* to diffuse against *Az. agilis* (V.J.) antiserum. *Az. agilis* (V.J.) has at least five antigens which may be numbered from the antiserum reservoir outwards for reference. One of the antigens (No. 4) has been found in all strains of *Azotobacter* so far studied. The fifth antigen, giving the heaviest line on the plates, is clearly complex and is occasionally seen to consist of numerous components (Fig 2) some of which are present in other strains of *Az. agilis* (Fig. 3). The details of the distribution by species of all the antigens

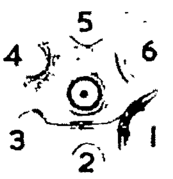

Fig. 1

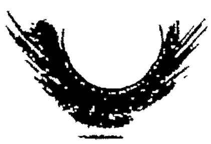

Fig. 2

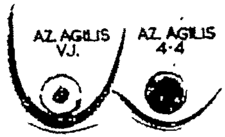

Fig. 3

Fig 1. Gel diffusion plate. Antiserum to *Azotobacter agilis* (V.J) in the centre. Antigens: 1, *Az. agilis* (V J.); 2, *Az. insigne* (V.J.5); 3, *Az. vinelandii* (0), 4, *Az. beijerinckii* (L.H.1); 5, *Az. chroococcum* (222), 6, *Az macrocytogenes* (0)

Fig 2. Gel diffusion plate. *Az. agilis* (V.J) antigen diffusing against the homologous antiserum. Photograph showing the complexity of antigen No. 5

Fig 3. Gel diffusion plate showing the partial sharing of the complex antigen No. 5 between two strains of *Az. agilis*. Antigen suspensions diffusing against *Az. agilis* (V.J) antiserum

are not yet completely worked out, but Table 1 summarizes the distribution as it is understood at the moment. The suggestion of a close relationship between *Az. agilis*, *Az. insigne* and *Az. macrocytogenes* is of great taxonomic interest. The closeness of *Az. agilis* and *Az. insigne* is well known[7], but the relationships of *Az. macrocytogenes* are not fully understood, although Johnstone[8] has shown that it shares with *Az. agilis* the ability to produce a water-soluble pigment giving a white fluorescence in ultra-violet light. I have noted a similar pigment in *Az. insigne* (unpublished observation).

Antisera active against *Az. chroococcum* have been prepared, and this work is being extended to include antisera to each of the species of *Azotobacter*. Attempts will be made to determine the chemical nature and position within the bacterial cell of some of these antigens, and a fuller report of the work will be published elsewhere.

I am indebted to Dr. J. G. P. Hutchison, of this Department, for advice concerning the drying and staining of gel diffusion plates.

Culture of *Desulphovibrio desulphuricans*

In a discussion about the method proposed by us[1] for the counting of sulphate-reducing bacteria in mixed population, Dr. J. R. Postgate pointed out in correspondence that, if one is handling a natural sample in which the population of sulphate-reducing bacteria out-numbers that of other micro-organisms, then the higher dilutions of such a sample are effectively pure cultures. Evaluation of our method with pure cultures of *D. desulphuricans* was obviously indicated. Dr. Postgate kindly furnished us with lyophilized pure cultures of the freshwater strain Hildenborough (N.C.I.B. 8303) and the salt-water strain El Agheila *Z* (N.C.I.B. 8380) of *D. desulphuricans*. Our experience in the culturing of both strains from the desiccates is summarized in Table 1; an iron nail in the medium clearly obviates difficulties in the revival of lyophilized cultures and, in addition, makes the exclusion of oxygen unnecessary. In a medium containing a nail, cysteine did not appear to be essential although it promoted earlier growth.

For comparing media for use in determining dilution counts of *D. desulphuricans*, decimal dilutions of a fresh culture in Starkey's medium (*LS*) were prepared in physiological saline, and 1 ml. of each dilution was transferred to each of five tubes of medium being tested. Incubation was at 30° C. for seven days. Some typical results are shown in Table 2. The results did not differ when cysteine hydrochloride (Merck) was included in *LS* + nail before sterilization or as Seitz-filtered solution just prior to inoculation. As autoclaving cysteine in presence of nail not infrequently resulted in slight darkening of the medium, it was found advantageous to add the flame-sterilized nail before inoculation. Neither Grossman and Postgate's[2] medium (*LSYC*) nor Starkey's medium containing a nail gave quantitative recoveries of viable bacteria. The inclusion of iron in the first medium or of an aerobic organism such as *Serratia marcescens* or *Aerobacter aerogenes* in the second permitted good growth. Addition of cysteine, yeast extract or peptone to *LS* + nail greatly improved the results. Such favourable effect was not apparent in the absence of nail. This suggests that in the presence of nail, cysteine acted chiefly as a nutrient (cf. Senez and Leroux-Gilleron[3]) rather than by poising the oxidation-reduction potential. The benefits given to aerobes do not seem to be simply due to oxidation-reduction potential changes as they gave occasionally poorer results than media containing cysteine and their effect was not apparent in the absence of nail. A question that requires elucidation is why the organisms in absence of iron nail found difficulty in initiating growth. It looks as if the nail provides an optimal surface for the initiation of growth, as the blackening

in the cultures invariably appeared first on the nail, and once growth is initiated the hydrogen sulphide produced helps the continuity of active multiplication because of its reducing properties. This interpretation finds support in the experiments on corrosion at Teddington in which growth was observed to start on the iron specimen (Postgate, J. R., personal communication).

Three media for dilution counts of *D. desulphuricans* were compared using soil containing a dense population of that species. The soil was prepared by placing 25 gm. of an air-dry, sieved clay loam in a tube, adding 6 ml. of a fresh *LS* culture of the 'Hildenborough' strain, and 6 ml. of sterile *LS* medium; the soil was then incubated anaerobically for 3 days at 30° C. Counts were then made using (*a*) *LS* + nail, (*b*) *LS* + nail, inoculated from one-day agar culture of *Serratia marcescens*, and (*c*) *LSYC* + nail. Results typical of those obtained in three trials appear in Table 3. They indicate that Starkey's medium plus nail is suitable for counting sulphate-reducing bacteria in natural materials containing large numbers of such organisms.

GENETICS

Differential Transmission of Gametes in Wheat

ONE of the basic principles of Mendelian genetics is that union of different gametes takes place at random, and genetic ratios are based on this assumption. In a few species, including *Vigna sinensis* Endb.[1] and *Hordeum vulgare* L.[2], the possibility of differential transmission of alleles has been suggested. The work reported here produces evidence that differential gametic transmission operates in wheat and gives rise to irregular inheritance patterns.

Investigators in Australia and North America have found that the varieties Gabo, Yalta, Charter, Lee and Timstein carry the same resistance to wheat stem rust, *Puccinia graminis* Pers. var. *tritici* (Eriks. and E. Henn.). Reports differ, however, as to the mode of inheritance of resistance. Workers in North America[3], using Chinese Spring as the susceptible variety, found evidence for two linked, dominant, complementary factors governing resistance (*Sr* 11 and *Sr* 12). Monosomic analysis located the two genes on the X chromosome, and linkage values of 20–29·5 per cent were proposed. Australian workers[4,5], on the other hand, using crosses with Federation, concluded that a single factor is involved.

Most of the data for this study were obtained from F_2 and F_3 generations of crosses involving the varieties Gabo, Yalta, Charter, Eureka and Mentana. The latter two were used as stem rust susceptible parents. Mentana is resistant to strain 68 *Anz*-3 of wheat leaf rust, *Puccinia triticina* Erikss. Seedling tests with leaf rust were carried out and the plants classified as resistant, intermediate or susceptible. In their reaction to stem rust, plants were clearly either resistant or susceptible.

Failure to obtain susceptible segregates in the F_2 of intercrosses confirms that the varieties Gabo, Yalta and Charter have the same gene or genes for resistance to race 126 of stem rust. In crosses of these three varieties with Eureka a single, dominant gene seemed to segregate. Crosses with Mentana, however, gave results similar to those reported by North American workers. They did not fit a single-factor hypothesis, and in the cross Yalta × Mentana a ratio of approximately 1 : 1 was evident (Table 1).

Table 1

	Resistant	Susceptible	Ratio	Probability (3 : 1)
Gabo × Eureka	462	161	2·9 : 1	0·70–0·50
Charter × Eureka	89	31	2·9 : 1	0·90–0·80
Yalta × Eureka	186	61	3·0 : 1	0·95–0·90
Gabo × Mentana	404	169	2·4 : 1	0·02–0·01
Charter × Mentana	500	226	2·2 : 1	<0·001 (9 : 7)
Yalta × Mentana	467	465	1·0 : 1	<0·001

Similarly, in studies of leaf rust resistance, there was inconsistency in F_2 segregation of crosses involving Mentana and the varieties Eureka, Spica, Kenya 117*A*, Gabo, Charter and Yalta. In the latter cross only a few susceptible F_2 seedlings were found. It was also apparent that the stem rust resistance of Gabo, Yalta and Charter was closely linked with the leaf rust resistance of Mentana. As these resistances entered the crosses in the repulsion phase it was thought possible that the unusual F_2 ratios might be explained by examining F_3 lines (Table 2).

Table 2. REACTION OF F_3 LINES OF CROSSES GABO × MENTANA AND YALTA × MENTANA TO STRAINS 126 *Anz*-1 OF *P. gr. tritici* AND 68 *Anz*-3 OF *P. triticina*

		Reaction to *P. gr. tritici*					
		Resistant		Segregating		Susceptible	
Reaction to *P. triticina*	Resistant	—	—	—	—	62	107
	Segregating	—	1	121	93	3	2
	Susceptible	40	4	—	1	1	—

First columns, Gabo × Mentana; second columns, Yalta × Mentana.

The results shown in Table 2 cannot be explained on a Mendelian basis. In both crosses close linkage in the repulsion phase between stem rust and leaf rust resistance is evident, and the different segregation ratios in the two crosses indicate that differential transmission of gametes is involved.

A striking feature in the F_2 ratio of the cross Yalta × Mentana was the low proportion of homozygous stem rust resistant lines. This, like the previous F_2 ratio of 1 : 1, could be explained by partial failure of pollen carrying the dominant allele. In many segregating F_3 lines, however, there was a considerable excess of susceptible segregates, and a second test of 14 lines confirmed this behaviour. The actual numbers were 150 resistant to 294 susceptible (χ^2 for a 1 : 1 ratio $= 46\cdot703$; $P = <0\cdot001$). This indicates that differential transmission operates in the female as well as in the male gametes.

A backcross Mentana × (Yalta × Mentana) tested with stem rust gave 2 resistant and 11 susceptible plants. The two resistant plants, when selfed, gave progeny in a ratio of 2·2 resistant : 1 susceptible instead of the expected 1 : 1. This contradicts the hypothesis that the mode of inheritance of resistance of Yalta is controlled by two or three dominant, complementary factors, as this hypothesis requires that the ratio in backcrosses to Mentana remain constant at 1 : 1.

These studies support the suggestion that there is only one factor for Gabo-type resistance. It is also likely that there is only one major factor for leaf rust resistance in Mentana. The main basis for these assumptions is the relative infrequency of crossing-over in the repulsion phase.

That partial sterility is the cause of these results is improbable. F_1 plants of Mentana crosses show no marked infertility; and the high germinability of the F_2 seeds does not indicate differential zygotic viability.

Further work will be done to find the mechanism causing this departure from random Mendelian segregation. It would also be of interest to determine whether chromosomes other than the X chromosome are affected.

Correlation of Loss of Photoreversibility of Ultra-violet-induced Mutations with Deoxyribonucleic Acid Synthesis

PREVIOUS work suggests that nucleic acid precursors altered *in vivo* by ultra-violet light serve as metabolic intermediates for mutation induction in *Escherichia coli*[1]. Other studies indicate that in the absence of an adequate source of nitrogen, an immediate and rapid decline in frequency of mutations induced by ultra-violet light occurs[2,3]. Prevention of this decline depends on the availability of a complex supply of amino-acids immediately following radiation exposure. The potential mutation is modified during post-irradiation incubation so that it is no longer subject to reversal by those agents inhibitory to protein or ribonucleic acid synthesis which cause decline in mutation frequency. Progression of loss of mutation susceptibility to chloramphenicol reversal is closely correlated with the post-irradiation synthesis of ribonucleic acid. Furthermore, experimentation has shown that a relation exists between the amount of post-irradiation ribonucleic acid which has been synthesized at the time of addition of chloramphenicol, the rate of synthesis of deoxyribonucleic acid in the presence of chloramphenicol, and the induced mutation frequency response obtained at subsequent plating[4]. These results suggest that ribonucleic acid and protein syntheses are required for mutation induction and synthesis of deoxyribonucleic acid following exposure to ultra-violet light. It would appear that only those cells which have synthesized the ribonucleic acid and protein necessary for genetic replication prior to addition of chloramphenicol are able to reproduce their deoxyribonucleic acid and thereby acquire mutant characters.

Recent studies of mutation expression have yielded further information on the relation of mutation induction to synthesis of deoxyribonucleic acid[5]. Mutation expression closely follows the initial net synthesis of deoxyribonucleic acid in irradiated cultures. Since chloramphenicol treatment subsequent to synthesis of deoxyribonucleic acid blocks this expression, protein synthesis following synthesis of the acid must take place in order for the induced mutations to be phenotypically expressed. The experiments we wish to report here relate to the involvement of synthesis of deoxyribonucleic acid in the mutation-induction process. These studies demonstrate that loss of photoreversibility of ultra-violet-induced mutation is closely correlated with post-irradiation synthesis of deoxyribonucleic acid.

The mutations studied result in reversion to the prototrophic state in *E. coli* strain *WP2* (a tryptophan-

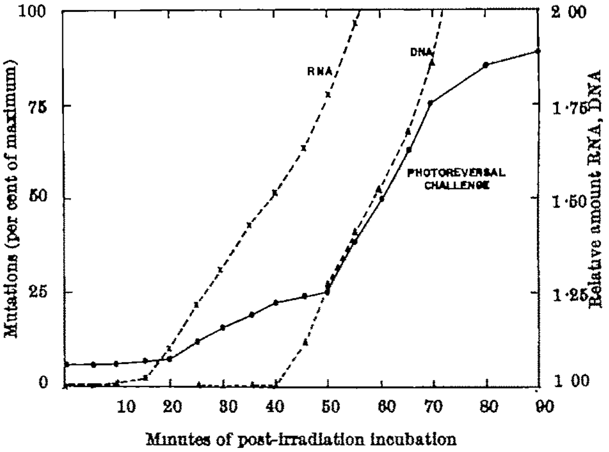

Fig. 1. The effect of challenge by photo-reversing light at increasing post-irradiation incubation intervals on the yield of ultra-violet-induced prototrophs from *Escherichia coli* strain *WP2*. Mutations are expressed as the percentage of those appearing in ultra-violet-irradiated control cultures which were incubated for an identical time interval and held for 1 hr. in an ice bath in the dark prior to plating. Photoreversal was carried out by subjecting ultra-violet-irradiated cultures to the light emitted by two 500-watt General Electric projection lamps. These were located 6 in. from the culture samples which were in small test-tubes immersed in an ice bath. The samples were exposed to the photo-reversing light for 1 hr., an exposure period which has been shown to produce maximum photoreversal. The incubation medium was minimal medium (ref. 1) plus casein hydrolysate (2 mgm./ml.) and DL-tryptophan (0·02 mgm./ml.). Ultra-violet exposure was 960 ergs/mm.^{2}. Induced mutation frequency response for unphotoreversed cells was approximately 8,000 prototrophs per 10^8 surviving organisms and did not vary significantly with incubation over a 90-min. period. Plating was on mutation assay agar previously described (see Doudney and Haas, ref. 3). Survival following this dose of ultra-violet radiation was approximately 50 per cent. The white light treatment resulted in photo-reactivation to the 70 per cent level of survival when applied without incubation. This effect was lost by 20 min. incubation. The cultures during incubation contained about 10^8 bacteria per ml. (as determined by colony formers observed with plating prior to radiation exposure)

requiring auxotroph isolated by Witkin). The procedures for culture growth, synchronization, radiation exposure, post-irradiation treatment, plating and mutation assay have been described, as have the procedures used for nucleic acid determination[1–3].

The loss of susceptibility of ultra-violet-induced mutations to photoreversal with post-irradiation incubation has been demonstrated with several systems[6–11] and a similar effect with the tryptophan reversion used here has been described[3]. Fig. 1 demonstrates that approximately 20 per cent of the potential mutations lose their capacity to be photoreversed prior to net measurable synthesis of deoxyribonucleic acid in the culture. However, the larger portion of potential mutations lose this capacity in correlation with synthesis of deoxyribonucleic acid. At the time that deoxyribonucleic acid has doubled (70 min.) approximately 80 per cent of the mutations are no longer susceptible to photoreversal.

Two processes may be involved in this loss of susceptibility to photoreversal. The initial process may represent some physical or chemical conversion of the radiation-modified factor responsible for the induction of the mutation to a non-photosensitive state prior to synthesis of deoxyribonucleic acid. However, the loss of susceptibility to photoreversal which is correlated with synthesis of deoxyribonucleic acid would seem to be due to actual synthesis of the mutated gene. These results therefore support the hypothesis that ultra-violet-induced mutation involves finally the synthesis of deoxyribonucleic acid following ultra-violet exposure[5].

These preliminary studies will be reported more fully elsewhere. This research was supported in part by research grant C-3323 from the United States National Institutes of Health and by U.S. Atomic Energy Commission Contract AT-(40–1)-2139.

SOIL SCIENCE

Symbiotic Nitrogen Fixation in a Grazed Tropical Grass–Legume Pasture

The importance of legumes as symbiotic nitrogen-fixers in the pastures of temperate regions is generally recognized, and considerable data are available to show the contributions made to the soil nitrogen supply by these legumes. Very little information of this nature, however, is available in the case of legumes growing in tropical pastures. Tropical legumes are often considered to be inefficient nitrogen-fixers; in instances where this is so, it is probable that inoculation with the appropriate *Rhizobium* strain or the supplying of deficient nutrients, or both, will increase fixation efficiency. Results obtained from an experiment on the Faculty of Agriculture Farm, University College, Ibadan, indicate that under suitable conditions the legume in a pasture growing under equatorial conditions may contribute amounts of nitrogen to the soil similar to those added by legumes in temperate pastures.

A grazing experiment comparing the productivity of a pure grass stand (*Cynodon plectostachyum*) and a mixed pasture (*Cynodon plectostachyum–Centrosema pubescens*) was established in mid-1953 and terminated in mid-1958. The soil of the experimental area was a latosol, Ibadan loamy coarse sand. On inspection the roots of the *Centrosema* were found to be well nodulated. The colour of the grass in the mixed pasture was a much darker green than that of the pure grass plot, suggesting that there were significant soil nitrogen differences between these plots. In September 1958 the plots were sampled to a depth of 12 in. and total (Kjeldahl) nitrogen of the samples determined. These nitrogen contents are shown in Table 1; to express the values in lb. per acre it was assumed that an acre-6-in. of soil weighed 2 million lb.

Table 1. SOIL NITROGEN (KJELDAHL) UNDER FIVE-YEAR-OLD GRAZED PURE GRASS AND GRASS–LEGUME PASTURES AT UNIVERSITY COLLEGE, IBADAN, NIGERIA

Depth (in.)	Soil nitrogen under *Cynodon plectostachyum* and *Centrosema pubescens* (lb. per acre)	Soil nitrogen under *Cynodon plectostachyum* (lb. per acre)	Difference in soil nitrogen (lb. per acre)
0–2	770	510	260
2–4	460	370	90
4–8	770	610	160
8–12	600	550	50
0–12 (Total)	2,600	2,040	560*

Each value is the mean of three replicates.
* '*t*' test: $P = 0{\cdot}10$.

There were 560 lb. of nitrogen per acre-ft. more in the soil under grass–legume than in the soil under grass. This was a net gain over a five-year period and may reasonably be attributed to symbiotic nitrogen fixation by the *Centrosema*. On an average annual basis the *Centrosema* had fixed 112 lb. of nitrogen per acre-ft. Thus the average annual increment of soil nitrogen due to *Centrosema* in this tropical mixed pasture was of the same order of magnitude as those for temperate pasture legumes. For example, Russell[1] states that clovers and lucerne may add to the soil 150–200 lb. of nitrogen per acre per year.

It appears that, under suitable conditions, pasture legumes may play as important a part in the nitrogen economy of tropical soils as they do in the case of temperate soils.

FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

Monday, February 29

University of London (in the Physiology Theatre, University College, Gower Street, London, W.C.1), at 5 p.m.—Dr. Antoinette Pirie . "The Biochemistry of the Eye".* (Further lecture on March 7).

British Society for the History of Science (in the Lecture Theatre of the Science Museum, Exhibition Road, South Kensington, London, S.W.7), at 5.30 p.m.—Dr. W. Cameron Walker: "Foundations of Current Electricity and Electro-Chemistry".

Society of Chemical Industry, Surface Activity Group (at 14 Belgrave Square, London, S.W.1), at 5 30 p.m.—Dr. E. G. Cockbain: "The Colloidal Stability of Natural Rubber Latex".

Royal Geographical Society (at 1 Kensington Gore, London, S.W.7), at 8.30 p.m.—Mr. A. J. Cain: "The Oxford University Expedition to British Guiana".

Tuesday, March 1

University of London (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 1.15 p.m.—Dr. A. J. Arkell: "An Archaeologist Visits the Belgian Congo".*

Institution of Electrical Engineers, Measurement and Control Section (at Savoy Place, London, W.C.2), at 5.30 p.m.—Scientific Papers.

Royal Society of Medicine, Pathology Section (at 1 Wimpole Street, London, W.1), at 5.30 p.m.—Prof. L. S. Penrose, F.R.S. . "Human Genetics and Disease"; Dr. H. Lehmann: "Familial Deficiency of Pseudocholinesterase"; Dr. A. Holzel · "Galactosæmia—a Hereditary Disease".

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. A. Isaacs . "The Anti-Viral Action of Interferon". (Last of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation.)*

Institution of Mechanical Engineers, Automobile Division (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Mr. Wheeler G. Lovell: "The Chemistry of Future High-Compression Engines" (James Clayton Lecture).

University of London (in the Beveridge Hall, Senate House. London, W.C.1), at 6 p.m.—Sir Douglas Logan: Birkbeck College Haldane Memorial Lecture.

Plastics Institute (at the Wellcome Building, 183–193 Euston Road, London, N.W.1), at 6.30 p m.—Dr. N. Grassie: "Recent Investigations into Polymer Degradation".

Society of Chemical Industry, Plastics and Polymer Group (at 14 Belgrave Square, London, S.W.1), at 6.30 p.m.—Dr. A. Keller: "Some New Aspects of the Crystallization of High Polymers".

Wednesday, March 2

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Mr. F. I. G. Rawlins: "Scientific Methods in the Care of Works of Art".

Institute of Petroleum (at 61 New Cavendish Street, London, W.1), at 5.30 p.m.—Mr. Michel Estavoyer: "Corrosion Problems in the Lacq Field".

Royal Meteorological Society (at 49 Cromwell Road, London, S.W.7), at 5.30 p.m.—Dr. H. L. Penman: "Weather, Soil and Plant Factors in Hydrology".

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. G. Schramm (Tubingen): "Mutagenesis in Viruses".*

Institution of Mechanical Engineers, Nuclear Panel (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "The Role of Formal Education and Training |in Nuclear Power Developments".

Thursday, March 3

Royal Society (at Burlington House, Piccadilly, London, W.1), at 10.30 a.m.—Discussion on "Problems of Stellar Evolution", opened by Prof. F. Hoyle, F.R.S.

Institute of Refrigeration (at the Institute of Marine Engineers, The Memorial Building, 76 Mark Lane, London, E.C.3), at 5.30 p.m.—Dr. E. Baumgartner: "European Refrigerated Transport by Railway".

Institution of Electrical Engineers (joint meeting with the Institutions of Civil and of Mechanical Engineers, at Savoy Place, London, W.C.2), at 5.30 p.m.—Sir Hugh Beaver, K.B.E. . "The Engineer and Civilization" (Sixth Graham Clark Lecture).

British Psychological Society, Education Section (in the University of London Institute of Education, Malet Street, London, W.C.1), at 6.15 p.m —Annual General Meeting. Prof. Allen L. Edwards (U.S.A.): "The Effects of Social Desirability upon Personality Measurement".

Friday, March 4

Zoological Society of London (at Regent's Park, London, N.W.1), at 10.15 a.m.—Symposium on "Sensory Specialization in Response to Environmental Demands".

Linnean Society of London (joint meeting with the Systematics Association, at Burlington House, Piccadilly, London, W.1), at 10.45 a.m.—Symposium on "The Subspecies". Speakers include Prof. Valentine, Dr. Hawkes, Dr. Warburg, Mr. Ross, Dr. Galbraith, Dr. Clay, Mr. Stroyan and Dr. de Wolf.

Royal Astronomical Society (joint meeting with the Royal Meteorological Society, at the Royal Society of Arts, John Adam Street, London, W.C.2), at 2.30 p.m.—Geophysical Discussion on "The British Rocket Programme". Chairman: Prof. Sir H. S. W. Massey, F.R.S.).

Institution of Electrical Engineers, Medical Electronics Discussion Group (at Savoy Place, London, W.C.2), at 6 p.m.—Discussion on "Direct Writing Oscillographs" opened by Mr. A. Smale and Mr. S. N. Pocock.

Society of Dyers and Colourists (at the Northampton College of Technology, St. John Street, London, E.C.1), at 6 p.m.—Mr. J. H. Sharphouse: "Recent Developments in Leather Dyeing".

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Sir Charles Darwin, K.B.E., F.R.S.: "Some Episodes in Darwin's Voyage on 'The Beagle'".

Saturday, March 5

British Interplanetary Society (in the Lancaster Room, Caxton Hall, Westminster, London, S.W.1), at 2.30 p.m.—Symposium on "The Exploration of the Moon".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant Lecturer (preferably with research interest in polymer chemistry, carbonyls or high-pressure reactions) in Organic Chemistry—The Registrar, The Manchester College of Science and Technology, Manchester 1 (March 5).

Lecturer in the Philosophy of Science—The Secretary, The University, 38 North Bailey, Durham (March 7).

Lecturer in Physical Chemistry; and an Assistant Lecturer in Zoology—The Registrar, Queen Mary College (University of London), Mile End Road, London, E.1 (March 8).

Senior Scientific Officer, Physical Chemist (with a first- or second-class honours degree or equivalent) at Warren Spring Laboratory, D.S.I.R., Stevenage, Herts, for work on electrochemistry of surface and colloidal reactions, forming part of a programme of research on fundamentals of froth flotation and mineral processing—The Ministry of Labour, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting Ref. F.79/0A (March 11).

Assistant Lecturers (2) (interested in plant biochemistry, experimental work with marine algae or genetics) in Botany; a Lecturer or Assistant Lecturer in Inorganic Chemistry; an Assistant Lecturer in Physical Chemistry; and an Assistant Lecturer in Organic Chemistry; an Assistant Lecturer in Geography; an Assistant Lecturer in Pure Mathematics and an Assistant Lecturer in Applied Mathematics; a Senior Lecturer in Physics; an Assistant Lecturer in Vertebrate Embryology and an Assistant Lecturer in Invertebrate Zoology—The Registrar, The University, Hull (March 12).

Curator of the Gulbenkian Museum of Oriental Art and Archæology—The Secretary, The University, 38 North Bailey, Durham (March 12).

Hospital Physicist, Basic or Senior grade (preferably with a knowledge of radiotherapy)—The House Governor, King's College Hospital, Denmark Hill, London, S.E.5 (March 12).

Lecturer (preferably with industrial experience or an interest in applied physical chemistry) in Physical Chemistry in the Department of Applied Chemistry—The Secretary, Northampton College of Advanced Technology, St. John Street, London, E.C.1 (March 12).

Lecturer, Terminable Lecturers, and an Assistant in the Department of Mathematics—The Secretary, The University, Aberdeen (March 12).

Assistant Lecturer in Physics—The Secretary and Registrar, University College of North Wales, Bangor, North Wales (March 15).

Lecturer (with a special interest in one or more of the following fields: soils, conservation, or land use) in Geography—The Secretary, University College, Gower Street, London, W.C.1 (March 15).

Lecturer (preferably with a special interest in semi-conductors and their applications) in Applied Physics—The Secretary, The University, 38 North Bailey, Durham (March 18).

Assistant Lecturer in Endocrine Biochemistry, to work in the University Endocrine Unit at the Liverpool Radium Institute—The Registrar, The University, Liverpool, quoting Ref. CV/T (March 19).

Lecturer (with some experience in microscopic anatomy or electron microscopy) in Anatomy—Joint Clerk to the University Court, Queen's College (University of St. Andrews), Dundee (March 19).

Lecturer or Assistant Lecturer (with special qualifications in palæontology or stratigraphy) in Geology—The Registrar, The University, Sheffield (March 19).

Lecturer in Psychology—The Secretary, The Queen's University, Belfast (March 21).

Lecturer in Physics at the University of Cape Town, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (South Africa, March 22).

Chair of Metallurgy—The Registrar, University College of South Wales and Monmouthshire, Cathays Park, Cardiff (March 26).

Lecturer in Botany—The Secretary, The University, 38 North Bailey, Durham (March 26).

Lecturer (with research experience in physical oceanography or in an appropriate branch of physics or mathematics) in Physical Oceanography—The Secretary and Registrar, University College of North Wales, Bangor, North Wales (March 29).

RESEARCH FELLOW (with research experience in biochemistry or chemistry and interest in the physico-chemical aspects of biochemistry) IN THE DEPARTMENT OF PHYSICAL BIOCHEMISTRY, John Curtin School of Medical Research, Australian National University—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (March 30).

CHAIR OF MEDICINE tenable at Charing Cross Hospital Medical School—The Academic Registrar, University of London, Senate House, London, W.C.1 (March 31).

LECTURER or SENIOR LECTURER (with research experience in statistics) IN MATHEMATICS—The Secretary, The University, 36 North Bailey, Durham (March 31).

LECTURER IN PSYCHOLOGY at the University of Adelaide, Australia —The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, March 31).

PRINCIPAL (with high academic qualifications and appropriate educational and administrative experience) OF THE NORTHERN POLYTECHNIC—R. H. Currell, F.C.A., Northern Polytechnic, Holloway, London, N.7 (March 31).

SENIOR LECTURER IN THEORETICAL PHYSICS at the University of Cape Town, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (South Africa, March 31).

READER IN PHYSIOLOGY at King's College, Strand, London, W.C.2 —The Academic Registrar, University of London, Senate House, London, W.C.1 (April 1).

READER IN MATHEMATICS at King's College, Strand, London, W.C.2—The Academic Registrar, University of London, Senate House, London, W.C.1 (April 4).

ELECTRON MICROSCOPIST IN THE DEPARTMENT OF PHYSICAL BIOCHEMISTRY, John Curtin School of Medical Research, Australian National University—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, April 18).

HEAD (with a good honours degree, preferably in physics or chemistry, experience of teaching and examinations at G.C.E. advanced level and also at degree level) of the Department of Science, Zaria Branch, Nigerian College of Arts, Science and Technology—The Council for Overseas Colleges, 12 Lincoln's Inn Fields, London, W.C.2 (April 29).

LECTURER IN PHYSIOLOGY (HISTOLOGY)—The Secretary of University Court, The University, Glasgow (April 30).

ACADEMIC REGISTRAR (graduate in science or arts, with teaching, industrial and administrative experience, and preferably knowledge of the work of a major technical college)—The Principal, College of Science and Technology, Ashley Down, Bristol 7.

ASSISTANT CLINICAL BIOCHEMIST (basic grade)—The Group Secretary, Booth Hall Children's Hospital, Blackley, Manchester 9.

BIOCHEMIST TO WORK IN THE ENDOCRINE LABORATORY, Obstetric Unit, mainly on steroids—The Secretary, University College Hospital Medical School, University Street, London, W.C.1.

CHEMIST (with a good honours degree in chemistry or equivalent professional qualification, and preferably specialization or experience in public analyst work) IN THE GOVERNMENT CHEMIST'S DEPARTMENT, Tanganyika, for general analytical work in the fields of toxicology, food and drugs, and water, and the supervision of assistants—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.117/8/037.

GRADUATE (with a knowledge of animal nutrition and/or agricultural chemistry) AT THE ANIMAL HEALTH TRUST FARM LIVESTOCK RESEARCH CENTRE, Stock, Essex, to assist in biochemical investigations—The General Secretary, Animal Health Trust, 14 Ashley Place, London, S.W.1.

LECTURER (preferably with university teaching experience and an active research interest) IN BOTANY—The Registrar, Queen Mary College (University of London), Mile End Road, London, E 1.

LECTURER (qualified to teach botany to B.Sc. and Diploma in Technology level, and preferably special qualifications in plant physiology or plant biochemistry) IN BOTANY—The Registrar, Bradford Institute of Technology, Bradford 7.

STATISTICIAN (with an honours degree in statistics or in mathematics with a diploma in statistics, and interested in the field of physiology) AT THE MEDICAL RESEARCH COUNCIL CLIMATE AND WORKING EFFICIENCY UNIT, Oxford—The Secretary, M.R.C. Unit, Department of Human Anatomy, South Parks Road, Oxford.

THE WORTH OF THE INDIVIDUAL IN MODERN SOCIETY

THE annual reports of successive presidents of the Carnegie Institution of Washington have earned a high reputation for the prescience and imagination with which they survey the varied aspects of the inter-relations of science and society and the contribution which the independent research institution can make. Nor are such problems surveyed from a narrow or nationalistic point of view, and it is not surprising that these reports are read with as much appreciation by British as by American readers, or that there is frequently to be discerned a striking parallelism between the trend of thought in the president's report and that disclosed in such current addresses of British men of science as the anniversary address to the Royal Society, a Reith Lecture, or a university lecture like the Fawley Foundation Lecture at the University of Southampton. Dr. Caryl P. Haskins's current report* is no exception, and its opening section, in which he considers the challenge which is offered to men and nations by times of severe stress, of profound change and radical adjustment, such as those in which we live, may profitably be considered alongside some passages in Lord Adrian's recent Fawley Lecture, "The Risks of Progress".

Dr. Haskins begins by pointing out that hazard is not the only, or even the dominant, quality of such times, which offer far more than mere tests of ingenuity in living to be met by essentially conventional, if strenuous, feats of adaptation and accommodation. If met with boldness, with balance and dedication, and above all with independence of mind and spirit, such times may also be times of unmatched opportunities for new orders of growth and self-realization, the ultimate benefits of which could far outweigh the short-term perils that pre-occupy and shadow our generation. Earlier generations living in times of comparable stress and change recognized the uncertainty and danger of their lives, but they realized also the enormous challenge of their days. To-day a new eagerness and audacity can be sensed, and a flavour of the immense significance of individual effort and achievement has come forward to our day. Each period is coloured by a certain dynamic fluidity —a special ability, possibly a special eagerness, to embrace the condition of change for its own sake, regardless of its specific content—and all seem to have attached a higher value to the dynamic process of living in their society than to the material consequences. New ideas were valued and exciting, and their communication was as important as their genesis. Exploration, or the search for innovation in one or another realm of experience, was specially valued.

No patterns, of course, as Dr. Haskins reminds us, are ever precisely repeatable, and although it is not surprising that we should find in our own age certain parallels with other ages which have been characterized, in the perspective of history, as creative or successful, in certain ways, he rightly adds, our challenge differs from that confronting earlier periods so greatly in degree as perhaps to be of another kind. In no earlier society can the challenge to acuity of comprehension, to specialized skills, to generalized insight, to the fullest development of individual capability in every field, have been so imperative, nor can the demand and the opportunity for individual development have approached those of our own day. In our age surely the stimulus, the demand and the opportunities for innovation, for individual creativeness, have reached unprecedented heights.

Dr. Haskins next directs attention to a qualitative difference in the practical technical demands of our times. Earlier dynamic ages have probably put first in their technical strategy the search for sources of physical power. Now the very success of that quest suggests that in future other aspects of our conquest of Nature, concerned more particularly with understanding and control, will assume a more conspicuous place in our technology, as is already happening. In the future, they must emphasize further and give a keener incentive to a broader, perhaps subtler and deeper comprehension of Nature as a practical requirement of living.

Those observations point to the vital importance of education in the world to-day and to the soundness of the philosophy displayed in the first part of the recent Crowther Report. Dr. Haskins goes on to bring this out even more clearly when he shows that for nations, as for men, times of unusual stress and challenge are a supreme test, not alone of effectiveness in action, but also and primarily of inner cohesion and verve, of inner wholeness. The severest practical challenge can be met successfully by a people only in its own characteristic fashion, consonant with its own most deeply held values. Unless these are adequate and are undegraded, the whole strength and balance of a nation will be inadequate.

We are not, Dr. Haskins reminds us, immune from the dangers which swiftly eroded some of the great ages of the past. We are faced by practical technical challenges of a national and an international character in which the search for knowledge and understanding of Nature for its own sake is often linked with material achievements indispensable to our prosperity, or even essential for survival. In such a situation it is easy to mistake the end of the road for the road itself, and it is imperative accordingly that we should be clear about our deepest motivations, that we meet these challenges in our own way and by courses that will reinforce our own ethic. Whether we are individually directly concerned or not with scientific matters, we must comprehend the values that underlie the search for scientific verities and appreciate how vividly they mirror our more generalized ethic.

---

* The Report of the President of the Carnegie Institution of Washington, 1958–1959. Pp. 54. (Reprinted from *Carnegie Institution of Washington Year Book* 58, for the year 1958–1959.) (Washington, D.C.: Carnegie Institution of Washington, 1959.)

The three points of anchorage which Dr. Haskins picks out from the philosophy of American society for special emphasis are no less part of the philosophy and tradition of Britain. First, there is that primary dedication to the individual and to his creativeness, that over-riding commitment which reveals the national stature primarily as a function of the welfare and perfection of realization of the worth and stature of the individual. This, Dr. Haskins writes, has been America's particular national pride to cultivate and foster, and on it depend the fundamental orientation and integrity of her society.

The second and third, like the first, may equally be regarded as part of America's heritage from Britain. The basically religious culture of America is closely linked with the first element, and though the dedication to the individual may be identified too narrowly with the Calvinist tradition from New England, it is undoubtedly largely derived from roots that are not materialistic. The third well-spring is a deep respect for, and concern with, both learning and innovation, and especially the exploration of Nature. The American people have traditionally loved the challenge of technical change; but equally the search for natural knowledge purely for its own sake is deeply indigenous in American culture.

Dr. Haskins recognizes, of course that in doing this science does no more than any other creative intellectual activity; but nevertheless, in its dedication of individual effort, its primary seeking after universally communicable knowledge of the natural world, in the discipline of its economy and its parsimony, and in its sense of style, scientific research must be reckoned to-day as one of the essential bulwarks of the deepest national values of the United States. That is largely true of other Western democracies, and in those democracies also material success offers a strong and continuing threat to such a non-materialistic ethic. It is not only in the United States that society needs a more explicit image of the real nature of its deepest motives—an image to which science may have an important part to contribute.

At this point Dr. Haskins touches on the problem of the two cultures as outlined by Sir Charles Snow. Whether or not this gulf arises from the confusion of application with creation—of regarding the scientific process as primarily an ever-expanding fount of technical product—the most serious danger is not in the field of education or communication, but rather that the divergence of experience may set and harden a real and fundamental dichotomy of attitudes and values between the two worlds, and encourage an unbridgeable hostility between them. The threat of such a fundamental division between the scientific and non-scientific world arises primarily from the divergence or misunderstanding of values rather than from unfamiliarity of subject-matter. Such a sense of division is inherently dangerous, and Dr. Haskins emphasizes some of the more serious hazards.

First, noting the consistent exponential growth of fundamental research since the time of Newton, doubling in volume approximately every ten or fifteen years, and at an appreciably greater rate than many other activities, he suggests that such a range and sweep of scientific effort must involve not merely the re-making of our culture materially but also the depletion of other creative activities in art, literature and humanism. This, of course, is one of the aspects of university expansion, particularly with regard to scientists and technologists, which already causes much concern in academic circles and elsewhere. If the gulf between the realms of science and other departments of human activity is indeed unbridgeable, involving irreconcilable differences of value and motive, the position is serious, for it implies that science must inevitably be permanently competitive with other areas of human effort.

While this could reduce the multivariant range of skills and interests which society needs to-day—and must indeed seek to encourage and expand—Dr. Haskins can point to evidence on the other side. Good minds in science, for example, tend also to be naturally good minds in other fields, and often to seek spontaneously the common denominators among them. Again, some of the most impressive scientific disciplines of to-day can be traced back historically in an almost unbroken evolution of ideas to representations of beauty and order in Nature on the part of eighteenth-century observers, in a pattern which to-day we might characterize as more artistic than scientific.

Even more significantly, perhaps, Dr. Haskins refers to the way in which, one by one, over the years, the barriers of attitude, of ways of thinking and modes of attack which, since the time of Newton, have traditionally segregated the concerns of science, put them in contrast with, and set them apart as narrower and somewhat different from, those of the rest of the world, are, in the larger philosophical sense, being penetrated. Post-Newtonian scientists knew, or soon discovered, that they must restrict their framework of scientific investigation to a limited segment of the world if their methods were to be applied successfully, and they ultimately paid with a highly disciplined parochialism for added depth and penetration; the notion of an unbridgeable dichotomy between scientific and extra-scientific orientation and concerns may be in part a consequence. A dramatic widening of the areas of scientific concern, with a progressive lowering of old barriers, however, is one of the major characteristics of our age, and it is conceivable that our notions about the separateness of the concerns and the domain of science from the rest of the world may become further blurred and ultimately fade.

When and if that occurs, it will come about, not by one view of the world replacing another, but rather by a convergence on common interests and a common kingdom. Such a development may prove to be the most powerful of all levellers of barriers, the most effective of any bridges spanning the gulf between the scientific and non-scientific points of view in the years to come. Unlike Lord Adrian, Dr. Haskins is unconcerned by the way in which in our time academic science and its relation to technology and industry have been violently forced out of the pattern which Huxley prescribed for science in the

Victorian period. The risks of progress at which he looks are intellectual rather than physical, and he believes that our concern that the exponential growth of scientific effort may disastrously pre-empt our human resources of mind and spirit may prove to be largely irrelevant.

Uncommitted scientific research, however, has a broader and deeper task than the winning of new knowledge, and apart from its contribution to essential human values, within its framework of opportunities, its breadth of horizon, its range of concepts and of problems, it has an important general obligation to discharge. In a vast technological society such as ours, bigness rather than success threatens the sanctity and maintained sense of worth of the individual. Survival depends on skilfully and successfully marshalling the work of myriads of individuals into the achievements of organized groups, and it is far too easy to forget that the very essence of creativeness must lie with the individual as contrasted with the group; the greatest strength of the group may be, at another time and in another place, to develop the full consequences of the vision of the individual.

That, Dr. Haskins insists, in conclusion, is what the research environment must stand for. To provide for the probity and the freedom of choice and action, to furnish the dynamic facilities for broad contacts and wide communication; and simultaneously, the shielding and opportunity for isolation that are so important to innovation and so precious at its most sensitive and valuable point; to foster flexibility and growth in the disciplines with which it is concerned—these are important and essential tasks. Yet more widely and profoundly significant, however, is its duty of manifesting its spirit as a society devoted to and sustained by the earned dignity of the individuals composing it. This is indeed the image of our larger society, which, as that society must be constantly reminded, alone can give it meaning, autonomy and authority. However successfully such a society may avert the physical risks on which Lord Adrian touched, it will not long endure unless it looks within and ensures that spiritual renewal and maintenance of values for which Dr. Haskins pleads so earnestly and well.

ZOOLOGICAL BORDERLANDS

On the Track of Unknown Animals

By Dr. Bernard Heuvelmans. Translated from the French by Richard Garnett. Pp. 558+52 photographs. (London: Rupert Hart-Davis, Ltd., 1959.) 35*s*. net.

BOOKS, like fashions, seem to follow cycles. The past decade has seen the appearance of several works devoted largely to speculation on the identity of mysterious unknown animals, descriptions of 'living fossils', and accounts of the more striking of the zoological discoveries of the present and past century. Possibly the sensational discovery of *Latimeria* in 1938, and the interest aroused by reports of unknown ape-like creatures in the Himalayas, have helped to popularize such topical books. In his preface, Dr. Heuvelmans has acknowledged his indebtedness to earlier writers in the same field; but it must be acknowledged that his is the most comprehensive, the best written, and certainly the most challenging work of its kind. The amount of research, as indicated by the extensive bibliography, must have been enormous, ranging from early classical writers to modern travellers and naturalists. Whether Dr. Heuvelmans is discussing the legendary Nittaewo (the lost people of Ceylon), the abominable snowman himself, or the supposed great aquatic reptile of Central Africa, his net is spread far and wide to bring in all available accounts and evidence. His ingenuity in linking legends, native stories or hunters' tales to produce a composite picture of some animal not yet recognized by science is praiseworthy, and certainly produces a great deal of engrossing reading matter.

But enthusiasm for the subject, allied to a fertile imagination, has resulted in a certain one-sidedness of approach, and many of his suggestions and conclusions, ingenious as they may be, lead to a feeling that the reverse of the medal has not been shown, or has been too briefly mentioned. It is the author's expressed conviction that some at least of the larger animals believed to have been long extinct are still surviving, and that there are also still unidentified large creatures, known only from native reports, or other hearsay evidence, concealed in the less well explored regions of the Earth. The many important zoological discoveries of the past hundred years or more are, in his view, only an indication of many more yet to come, rather than the natural consequence of the rapid opening up of so many of the wilder places of the Earth during that period.

It is in the development and illustration of this theme that the author allows his antipathy to the professional zoologist to colour all his views and warp his judgment. It appears that the professional zoologist, almost without exception, has resolutely turned a deaf ear to all reports of unknown animals, and has stubbornly refused to consider the possible existence of any creature the bones or skin of which are not on the museum table. In defence of the maligned professional, it should not be necessary to point out that it is only in relation to the established and known that the unestablished and unknown can be considered, and that the essential reference works and catalogues listing the multitudinous life around us are largely the work of the professional systematists. The accusation that zoologists are more concerned with adding names to the literature on insufficient grounds comes ill from a writer who, in this book, proposes three new specific names and one new generic name on the most tenuous of evidence, while ignoring most of the established rules of taxonomic procedure. Dr. Heuvelmans defends his proposal of the new name *Dinanthropoides nivalis* (p. 178) for the abominable snowman (the evidence being photographs of tracks in the snow and photographs of a scalp not proved to be associated with the animal making the tracks) on the incorrect ground that "this procedure is not only universal in palæontology, but happens fairly often in zoology". In support, he quotes the first description of the giant panda, the alleged Andean wolf, the takahe (*Notornis*), the pygmy hippopotamus and the okapi. In actual fact none of these were named until tangible specimens, whether skins or skulls, were examined and compared.

This bias against the professional leads Dr. Heuvelmans to turn for support for his views to writers about whose reliability and status there can be widely differing opinions. Even the introduction by the well-known author and collector of live animals, Gerald Durrell, is coloured by the same bias. Incidentally the latter's statement that the okapi was known only as an extinct relative of the giraffe until it was discovered living is quite inaccurate, and his reference to the 'surprising' discovery of the king cheetah in Southern Rhodesia is less convincing when it is known that the animal is no more than a colour mutation of the common cheetah.

In a work of this scope and length there are inevitably a number of errors and inaccuracies. A more careful checking of references would have avoided many of these. But the most serious charge that can be made is the over-emphasis on hearsay and unsupported tales which are quoted as evidence for the existence of some hypothetical animal, and the arrangement of factual evidence to support a case. For example, Fig. 81 (p. 314) is a sketch, full face, of the head of the alleged South American anthropoid or Loy's monkey, based on the photograph which is the only material evidence. In the photograph of the dead monkey the jaw sags, resulting in an unnatural appearance. In the sketch, shown with mouth shut, the face is compared with a reconstruction by von Koenigswald, 1938, of the face of *Pithecanthropus*. We are then told that if one disregards the many features in the *Pithecanthropus* face which cannot be inferred from the bones, and must therefore have been invented, the shape of the face is the same in the two. The author continues—"Although it [Loy's monkey] has been photographed full face, one can see that its profile is more like that of a capuchin monkey" (rather than a spider monkey, with which this animal is identified by primate specialists). Such ingenious presentation of evidence does not give one a great deal of faith in Dr. Heuvelmans' ability to hold a fair balance.

Again, in the case of the king cheetah (pp. 419–420), the description by R. I. Pocock in 1926 of what was thought at the time to be a very distinct new species is used as an illustration of how unreported animals can survive in a settled area for many years without discovery. But Dr. Heuvelmans does not tell the reader that in 1939 Pocock published his own conviction that this was not a new species after all, but simply a pattern mutation of the common cheetah. An illustration of the printing at full length of stories which eventually prove to have a prosaic ending is found in Chapter 20, devoted to the possibility of pterodactyls and other prehistoric reptiles still existing in Africa. Ivan T. Sanderson's vivid account of an encounter with a great black flying creature in the Cameroons (p. 491) is followed by a long discussion of its possible identity. But the footnote (p. 494) in which Sanderson is quoted (*in litt.*) as saying that the 'thing' was a bat, reduces the value of this contribution to nil.

Misquotations are frequent. The water civet, *Osbornictis piscivora* (p. 64), was discovered in the Ituri Forest not by Glover Allen in 1919 but by the collectors Lang and Chapin (of Congo peacock fame) in 1913, and it was Dr. J. A. Allen who described it in 1919. A skin and skull purporting to belong to a Nandi bear sent to the British Museum (Natural History) came not from Nyasaland (pp. 399–400) but from Uganda, hence Dr. Heuvelmans' comment on the unlikely locality has no validity. Again, we are told at the conclusion of the Nandi bear section (p. 414) that "Ivan T. Sanderson says that in the British Museum of Natural History there is a piece of fur [*sic*—'peau' in the original French edition] covered with long brown hair which may come from the animal about which armchair experts are so sceptical". If the author had checked this statement with the Museum he would have found that in fact no such piece of skin is known there.

In the class of over-confident assertions are the following. "I have shown that the Earth may still hold plenty of large unknown animals" (p. 81); "Herds of hundreds or even thousands of mammoths could easily live there [in the Siberian taiga] without running the least risk of being seen by man" (p. 350); of the alleged pygmy gorilla, named by Elliot *Pseudogorilla mayema* in a notoriously unreliable work, he says (p. 63) "The existence of this species, about which we know so little, has never been in doubt". Reference to current African primate literature would have shown Dr. Heuvelmans that, on the contrary, this name has long been relegated to the synonymy of the ordinary lowland gorilla, *Gorilla gorilla*. Do elephants, rhinoceroses and hippopotamuses really make the Earth shake, as we are told (p. 449) after reading of a Belgian in the Congo who felt a violent earthquake when a mysterious giant beast moved off unseen in the forest?

The basic natural history is often unreliable. It is not true that (p. 197), apart from species imported by man—the dingo and the rats, and several bats which could have flown across the sea—there are no wild placental mammals in Australia. There is a varied native rodent fauna, including 17 genera with 79 species, which has evolved over a very lengthy period in that continent. There are no macaques in Central Africa (p. 358). The account of the habits and distribution of the sea otter, ***Enhydra lutris***, of the North Pacific coasts, in connexion with its suggested identification as the waitoreke of New Zealand mountain waters, is largely inaccurate. The "pack of 400 seen swimming down the Californian coast in 1938" (p. 248) (presumably on their way to the Antipodes) turns out on investigation of the source quoted to refer to a much lower number of resident sea otters recovering their former status on the Californian coast, and it would be interesting to know how the "large numbers [of sea otters] along the coast of southern Chile, which seems to imply an extraordinarily long migration" reported by a quoted observer, were identified. There is a local South American coastal otter, *Lutra felina*, found commonly in those waters, which probably accounts for this confusion.

Despite these numerous criticisms, I found this book, illustrated by many photographs and sketches, very readable and sometimes stimulating. One can part company with many of the author's conclusions without denying that he has produced a useful work. He may be reassured to learn, meanwhile, that zoologists are not all quite as blind and deaf as he suggests, and that while they are waiting for some of the animals so vividly described here to appear in the flesh, they are not entirely idle. In the five years, for example, since the publication of the original French edition of this book, no less than four distinct and quite unexpected new genera of small mammals (all small enough to be beneath Dr. Heuvelmans notice) have been described from tropical Africa, and no doubt other regions will contribute their quota in due course. R. W. Hayman

MARKET STRATEGY AND ECONOMIC SURVIVAL

Strategy and Market Structure

Competition, Oligopoly, and the Theory of Games. By Dr. Martin Shubik. Pp. xviii + 387. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1959.) 64*s.* net.

IN 1944 there appeared "Theory of Games and Economic Behavior", the pioneer work by von Neumann and Morgenstern, full of promise for a uniform and dynamic theory of the firm on a new game-theoretic basis. In the subsequent fifteen years, game theory was developed and applied in many directions, but not to any effect in the theory of oligopoly and monopolistic competition, of the firm under various market conditions. What was sown in 1944 is at last bearing fruit, ample evidence being provided by this text by Dr. Shubik. It is possible to envisage now the bridging of that wide gap, disturbing to so many economists, between the traditional theory of the firm and practical business as understood by institutional economists and business schools. This is not to say that Dr. Shubik has constructed the bridge. His book is still rather severely theoretical. But he does take into account many factors which have hitherto been rather baffling—the influence of the financial strength of a firm, its technical position and its corporate form—and he has so framed his theory that empirical work can be based upon it.

Dr. Shubik achieves two quite different objectives in dividing his book into two halves. In the first part he makes a game-theoretical exposition of existing theory and throws much new light on it. In a firm under pure competition or pure monopoly, the *entrepreneur* makes his decisions on his own and economic theory has long been able to handle the situation. Under what can be described either as oligopoly or as monopolistic competition, at least one firm in planning strategy on the market for a product must take into account the influence of at least one other firm on the same market. There is then a great variety of possible market structures, according to the varying number of firms and their different situations (for example, on transport costs), according to the extent of product differentiation, and according to the relative bargaining powers or market leadership of the firms. There is competition between firms but also co-operation, coalition and collusion. This is just the kind of situation to be exploited by game theory. Duopoly as analysed by Cournot and Edgeworth is such a special case that it cannot serve for generalization. The theory of monopolistic competition as elaborated by Chamberlin and Joan Robinson is piecemeal and lacking in the essential unifying principles. Dr. Shubik succeeds in his game-theoretical approach where the traditionalist development failed.

In the second part, Dr. Shubik attempts something even more important. This is a sketch of a truly dynamic theory of oligopoly, or rather the basis on which such a theory might well be built. He allows for imperfect information among the constituent firms on a market. His starting point is the concept of a particular type of game, the game of economic survival. A game of survival or ruin is well known as an extension of an ordinary zero-sum game, applied in successive periods until one player uses all his funds and is ruined. A game of *economic* survival is again a zero-sum game as long as the contestants survive (for example, splitting up a given market) but with a bonus to the ultimate survivor. On this view, the economic activity of the firm is to maximize something, generally the stream of dividends over time, but subject to attention being paid to survival. Not all the experts in this field go all the way with Dr. Shubik in his development of the theme, but none can deny that he is pursuing with great ingenuity something very well worth while. This is an important book, not only for game-theorists, but for all economists.

R. G. D. ALLEN

THE DARK AGE IN AFRICA

Old Africa Rediscovered

By Basil Davidson. Pp. 287 + 28 plates. (London: Victor Gollancz, Ltd., 1959.) 25*s.* net.

THIS book is an attempt to accomplish the well-nigh impossible; but because the author knows a great deal about the late prehistory of many parts of Africa and can put down his knowledge in a clear and interesting manner, it is well worth perusal. It has been said that a few years ago such a work would have been impossible owing to lack of information; it can equally be said that a few years hence such a work will be quite impossible, except in the form of many volumes, because of too much data. At the same time, the reader should clearly understand the scope of the book. It is true that in the short introductories there is mention of pluvials, early lines of migrations, etc., but the author is not really concerned with very early times, his interests centring on the epoch from about 500 B.C. to the opening up of the continent by the Europeans.

As this is, perhaps, the period least understood in most African regions, the book will be very much welcomed. Of necessity the areas dealt with are somewhat scattered, but the account of the pre-Portuguese civilizations, which flourished along the east coast, and which Dr. Mathew has done so much to reconstruct, is of especial interest. Much, however, has not been included. The bulk of the rock-shelter art, at least in the Union of South Africa, falls within the author's period—indeed some of the finest of the polychromes probably date no farther back than the sixteenth century A.D. *Pace* one carbon dating, it is quite likely that the same applies to the Nachikufan culture of Northern Rhodesia at least in its later phases. This is indeed mentioned but discussed as dating to 4000 B.C. But the dating of early cultures in Africa is a notoriously controversial subject and need not be pursued further here.

It is true that the spine of the Sahara desert has been well-nigh impossible for human migration since Gamblian (last pluvial) times, but subsequent wet phases, the last one of no vast antiquity, have permitted human occupation in the fringes bordering the spine both on the north and the south, and once again much of the rock-shelter art in these regions belongs to Mr. Davidson's period. The description of the ancient town of Meroe with its great slag heaps and the Kush civilization is very well set out, and to many readers the account of Bernard Fagg's splendid pottery figurines from Nigeria which up to now have not been well published will be welcome indeed. Quite rightly, Dr. Manny's work in West Africa is noticed, and the early history of Benin is not forgotten. As has been said, the civilizations which grew up along the east coast of Africa and the (to some extent) contemporary Rhodesian buildings are treated at considerable length. The history of the early Congo is scarcely mentioned, nor is that of Angola, though the publications of the Diamond Company there have shed some light on its obscure part. The Union of South Africa, except for a brief account of Mapungubwe, is also omitted.

These gaps (geographically) are numerous, but it is difficult to see how everything could have been included in one short volume. What the author has given us is excellent reading, and he is to be congratulated on attempting what for many would have seemed impossible. It is a work which many people who care about Africa will warmly welcome.

M. C. BURKITT

IMPORTANT RAW MATERIALS

Cellulose Pulp and Allied Products

By Dr. Julius Grant. (Incorporating the third edition of "Wood Pulp".) Pp. xvi+512. (London: Leonard Hill (Books), Ltd., 1958.) 50s. net.

REFERENCE books of any size are now usually assembled by editors from chapters written by different authors—each an expert on his own subject. "Cellulose Pulp" is a survivor from an older tradition, and is the work of one author. This gives a uniformity in style, lacking in a collection of edited chapters, but anyone essaying a subject with as vast a literature as cellulose pulp sets himself a difficult task.

This book incorporates the third edition of "Wood Pulp", which was first published in 1938. Wood is quite the most important source of cellulose pulp (about 90 per cent) of the total and most of the book is concerned with the manufacture of wood pulp. The central chapters cover this well and should be of use to the general reader who is not 'highly technical' in accordance with the author's wishes expressed in the preface. Chapter 2 on history is well done, but the author could have made more of the history of wood pulp technology itself. Without wood pulp paper would have been so scarce that Forster's (Compulsory) Education Act of 1870, and similar measures in other countries, would have been useless. It is no good teaching children to read and write without adequate paper supplies, and the figures quoted by the author for paper consumption and literacy in Asia and Africa show that the problem is still with us.

Appropriately enough the main untapped source for pulp is in the tropical forests, but it is not easy to get sound information about them quickly as an enormous variety of trees grow in mixed stands and they all have different pulping properties. There is a serious sampling problem, and it is also very difficult to forecast the nature of the secondary growth, which is most important if pulping is to be put on a continuous basis.

In briefly relating his subject to cellulose technology in chapter 3 the author has run into some difficulties. The explanations of 'micelles' on page 37 and 'tracheids' on pages 49 and 50 are so short that they are misleading. Chapters 20, 21 and 22 on uses of cellulose also suffer from enforced brevity. The rayon and allied industries, and the plastics industry too, may be surprised at the small space given to their special problems. In most parts of the book sufficient references are given to enable the scientific reader to look up detailed information elsewhere, but the references to the uses of pulp are thin considering the variety of processes mentioned.

These, however, are not major issues and it is hoped that the book will be widely read for its manufacturing section. Too few people realize how important pulp technology is to our civilization.

F. LYTH HUDSON

THE CASE FOR EXTRA-SENSORY PERCEPTION

The Sixth Sense

An Inquiry Into Extra-Sensory Perception. By Rosalind Heywood. Pp. 224. (London: Chatto and Windus, Ltd., 1959.) 21s. net.

IN this volume Mrs. Heywood, an active member of the Council of the Society for Psychical Research, has collected a mixed but well-arranged selection of those cases which seem to her and doubtless to many others to offer good evidence for extra-sensory perception. She is convinced that both in England and in the United States experiments have been conducted under rigid scientific conditions which have shown that it is possible for one person to become aware of another's thoughts and feelings where such information could not in any circumstances have been acquired by sensory means.

Beginning her study with a glance into the past, she briefly summarizes the early work of the Society for Psychical Research, stressing the value of its experiments and conclusions without, however, adequately dealing with the objections to its methods which were often voiced at the time. Proceeding with her analysis she discusses the work carried out on the problem of mediumistic communications, especially those associated with the names of Mrs. Piper, Mrs. Leonard and Mrs. Coombe-Tennant. The very puzzling "Cross-correspondences" are then dealt with, and the two chapters devoted to them form an excellent introduction, although the author fails to appreciate the reason why this material has never attracted the attention that it might deserve if we knew all the facts and not only some of them. The study is concluded by a short discussion of various quantitative experiments and a short summary of some of the explanations and hypotheses that have been offered.

As a popular and necessarily brief introduction to extra-sensory perception this book is to be recommended, although always with the proviso that the facts are as stated and that further knowledge of the conditions would confirm the interpretation put upon them. It is this lingering doubt about the accuracy of the records that tends to prevent so many scientific men from taking many of the statements of psychical research workers too seriously, and this hesitation is often better justified than at first appears.

In this book Mrs. Heywood has done little to allay such doubts. What she has done is to present a further stimulating and lucid study of extra-sensory perception which may prompt independent inquirers to initiate experiments on their own account, but only after an intensive study of the subject and of the pitfalls with which it abounds.

E. J. DINGWALL

TIZARD AND THE SCIENCE OF WAR*

By Prof. P. M. S. BLACKETT, F.R.S.
Imperial College of Science and Technology, London

The Air Defence Committee

IT is sad indeed that the newly founded institute for the study of war (the Institute for Strategic Studies) should so soon have to mourn the loss of one of its most distinguished members (*Nature*, 185, 209; 1960). I wish to attempt to assess the nature of Tizard's direct personal contribution to the Allied victory in the Second World War and to trace the great influence he exerted on the general study of war, which is, of course, the explicit object of the Institute for Strategic Studies. All men's careers have much that is accidental in them, and no doubt there was an element of chance in the selection in 1934 by the Air Ministry of Sir Henry Tizard, then rector of the Imperial College of Science and Technology, as chairman of the Committee for the Scientific Survey of Air Defence. But there was none in the brilliant and decisive manner in which Tizard exploited the opportunities thus given him, at a decisive moment of world history.

The military and political outlook of the middle 1930's was indeed ominous. The world economy was just beginning to stagger uncertainly out of one of the most disastrous slumps of history; Hitler had come to power in Germany and was openly preparing for war; the advance of aeronautical science and engineering had at last gone far enough to make it possible that air power might be a vital factor in a major war—if this were so, then the extreme vulnerability of Great Britain with her high population density and her close proximity to the mainland of Europe, which only too easily might fall into enemy hands, became of major military importance. As far as there was a military doctrine of the day, it seems to have been expressed in Baldwin's famous phrase in 1933 that "the bomber will always get through".

This, then, was the background to the first meeting in January 1935 of what became universally known as the "Tizard Committee"; its official terms of reference were: "To consider how far recent advances in scientific and technical knowledge can be used to strengthen the present methods of defence against hostile aircraft". In addition to the chairman there were originally only three members: H. E. Wimperis (then director of research at the Air Ministry), A. V. Hill (physiologist at University College, London) and myself, with A. P. Rowe (later to become the director of the famous Telecommunications Research Establishment) as secretary.

During its five years of existence—the Committee was dissolved during the first years of the War—four things of major importance were achieved, mainly through Tizard's vigorous and persuasive personality. Radar, which in Great Britain originated with Robert Watson Watt at the Radio Research Laboratory of the National Physical Laboratory, was energetically supported and, with the enthusiastic support of senior airmen, introduced secretly into the Air Force. When war came in 1939 the whole east and south-east coasts of England had their radar chains operational, and this was a decisive factor in the winning of the Battle of Britain in 1940.

The second indirect but very real achievement was to bring the senior officers of the Armed Services into much closer intimacy with the research and development scientists in the Government establishments. Tizard's gifts, which will be referred to again, of inspiring confidence in young and old, in those in authority and in those at the bench or on the gun-sites: his passion for getting things done and his flair for interpreting the military requirements to the bench worker, and the technically possible to the Service chiefs: all these greatly enlivened and made more productive the scientific and technical side of the Air Force in the first instance, and then by example the other two Services.

The third achievement was the creation of mutual confidence and understanding between serving officers and university scientists; so that, when need arose, and it did arise very soon, many of the best academic research workers flocked out of the universities into radar stations, and later into Service experimental establishments, where they became a vital part of the brilliantly creative, and sometimes obstreperous, teams, whose work had so profound an effect on the waging of the War.

The fourth achievement was the recognition that scientifically trained research workers had a vital part to play, not only (as of course was traditional) in the development of the weapons and gadgets of war but also in the actual study of operations. It was due to Tizard's personal initiative as early as 1936, before, in fact, radar data on approaching aircraft were available, that civilian scientists were attached to the Fighter Station at Biggin Hill to study the art of controlled interception, as it would have to be done, when a year or two later the radar chain would become operational. This experiment seems to have been the first official recognition that the actual operations of modern war are so complicated and change so fast that the traditional training of the serving officers and personnel is inadequate. In fact, many of the operational problems which arise when new equipment comes into service require for their solution the aptitudes of the scientific research worker: for he is trained to apply scientific methods to elucidate hitherto unknown and complex phenomena.

The Biggin Hill experiment was the first step towards the fully fledged Operational Research Sections attached eventually to all the major Commands of all three Services. A further important step was taken when, at the outbreak of the War, A. P. Rowe, then in charge of radar research at Bawdsey, sent a small group of scientists to Headquarters Fighter Command to study the actual use of the radar data so as to keep the radar scientists in the establishments briefed both on the actual performance of the sets in operations and on the real operational needs of Fighter Command. Out of this group grew the Fighter Command Operational Research Section as an integral part of the Command organization. Analogous developments took place at Anti-Aircraft, Coastal and Bomber Commands, and also at the Admiralty and the War Office. These developments implied a great measure of mutual trust and understanding between the senior Service officers and the often brash and initially very ignorant scientists—ignorant, that is, of most things that went on outside a university research department. This intimate relationship between professional fighting men in charge of operations and research scientists proved highly profitable, and some of the later operations of the War were carried out under a close scientific and statistical scrutiny. The pattern of organization and method worked out in Britain during the first years of the War stimulated similar developments in the United States. Hitler's Third Reich saw no such collaboration. No doubt the almost unbroken German military successes of the first war years confirmed the highly competent military staffs in the view that they had no need to seek help from outside scientists, however brilliant. When the tide of war swept against Germany it was too late. Luckily for the Allies, Germany never produced its Tizard.

---

* Tizard Memorial Lecture delivered on February 11 before the Institute for Strategic Studies.

The importance of bringing scientists into close touch with operations had been clearly foreseen during the early days of the Tizard Committee. It was well expressed by the Secretary of State for Air, Lord Swinton, then Sir Philip Cunliffe Lister. In his book "I Remember" he wrote: "There was nothing new in the use of men of science as advisors to Service Departments and to the Committee of Imperial Defence. . . . There was nothing new, therefore, in calling in science to help; but from the moment I went to the Air Ministry, I felt that in the air, with all its unknown possibilities, we wanted a much closer and more intimate relationship. The scientists who were to work with us must be from the start an integral part of the Air Staff". Of the Tizard Committee he wrote: " . . . they were at the heart of operational planning. That relationship was, and I believe always will be, the key to success in scientific co-operation".

Prominent among the senior Air Force officers who welcomed and co-operated closely with the Tizard Committee were Air Marshal Sir Cyril Newall, chief of the Air Staff 1937–40; Air Marshal Sir Hugh Dowding, Air Member for Research and Development 1930–36 and then commander-in-chief Fighter Command, and so the first operational user of radar; Air Marshal Sir Wilfred Freeman, who succeeded Dowding in 1936 as member for Research and Development; Air Marshal Tedder (now Lord Tedder), who was director-general for Research and Development during 1938–40; and Air Marshal Sir Philip Joubert, then air officer commanding Fighting Area and later commander-in-chief Coastal Command.

For the encouragement of the later developments of the application of scientific method to tactics and strategy, much credit goes to General Sir Frederick Pile at Anti-Aircraft Command, Admiral Sir George Creasy, then director of Anti-Submarine Warfare at the Admiralty, and Air Marshal Sir John Slessor, now a vice-president of the Institute for Strategic Studies. During Slessor's time as commander-in-chief Coastal Command 1943–45, the scientific analysis of the anti-submarine war became an accepted part of operational control, and statistics of air hours flown, rates of search, U-boat sightings, etc., were discussed at the fortnightly U-boat meetings at No. 10, Downing Street—once goading a senior officer to protest that wars were won by weapons and not by slide rules, so giving rise to the half-derisive but also appreciative term 'slide rule strategy'.

Unfortunately, Tizard published little about his own contribution to these developments, though no doubt much of great interest will be found in Whitehall files, when these become available to historians. So far as I know, his lecture to the Royal United Service Institution in 1946, entitled "Science and the Services", and his Haldane Memorial Lecture at Birkbeck College in 1955, entitled "A Scientist In and Out of the Civil Service", are almost all that are available: and in these, with characteristic modesty, there is little about his own achievements. So the history of these vital years has to be pieced together from personal memories.

Controversy on Priorities

Although the Air Defence Committee started up in January 1935 with only Tizard, Hill, Wimperis and myself as members, in July of the same year the Secretary of State for Air, under pressure from Mr. Winston Churchill, enlarged it by the addition of Prof. F. A. Lindemann (afterwards Lord Cherwell). It was not long before the meetings became long and controversial: the main points of dispute concerned the priorities for research and development which should be assigned to the various projects which were being fathered by the Committee. For example, Lindemann wanted higher priority for the detection of aircraft by infra-red radiation and for the dropping of parachute-carrying bombs in front of enemy night bombers, and lower priority for radar, than the other members thought proper. On one occasion Lindemann became so fierce with Tizard that the secretaries had to be sent out of the committee room so as to keep the squabble as private as possible. In August 1936, soon after this meeting, A. V. Hill and I decided that the Committee could not function satisfactorily under such conditions; so we resigned. A few weeks later Lord Swinton re-appointed the original Committee without Lindemann, but with Prof. E. V. Appleton, and a few months later with Prof. T. R. Merton, as additional members.

During the years 1935–39 the Committee investigated and assessed a large number of projects, good and bad; we visited many establishments and discussed all aspects of air defence problems with air marshals, with pilot officers and with scientists in their laboratories. Pre-eminent, of course, was radar, both ground and air-borne. The story of radar has often been told, and all I wish to emphasize is the vital part played by the confidence which Tizard did so much to build up between the senior airmen, the research workers and the responsible Cabinet ministers. The full backing of the Committee became an effective way of getting high priority given to a project. Without such mutual trust the scientific development of radar could not have forged ahead at such speed, nor would the tens of millions of pounds have been provided so rapidly and secretly by the Treasury to build the radar chain.

In 1937, Tizard was made chairman of another Committee, this time for the Scientific Survey of Air Offence, modelled on the lines of the Air Defence Committee. However, it failed to come to grips with the problems of the use of bombers and made no decisive impact. Possibly Tizard himself was too heavily involved in air defence problems easily to switch his interest: possibly the failure was partly due to the not very sympathetic response by those in the Air Force then concerned with bombing policy. Whatever the cause, I think it would be fair to hold that until the War was well advanced, Bomber Command was less scientifically minded than either Fighter, Coastal or Anti-Aircraft Command. Moreover, it was just this failure to think and analyse scientifically which delayed for too long the recognition of the extreme ineffectiveness of our early bombing offensive. Sir Winston Churchill tells how Prof. Lindemann in 1941 informed him that, of the bomber crews who thought they had found their target, it had been shown by analysing flash photographs that two-thirds were not within five miles of it. Once these facts were fully recognized, high priority was put on navigational aids of various kinds, and matters greatly improved.

Tizard's Mission to the United States

In November 1939, Tizard, then scientific adviser to the Air Ministry, suggested that A. V. Hill should go to Washington to act as scientific adviser to work with the Air Attaché, so as to get scientific help on defence problems from the United States. Since scientific developments were likely to play a major part in determining the issue of the War, the importance of attempting to get official approval for Britain to tap the vast scientific resources of the United States was very great. In a typically apt phrase Tizard described his policy as that of "bringing American scientists into the War before their Government". In this he succeeded in a startlingly successful manner. When A. V. Hill reached Washington, he realized that this objective could only be attained if a complete interchange of scientific secrets between the two countries could be arranged. With the help of the British Ambassador, Lord Lothian, President Roosevelt became convinced of the importance of such interchange, as were also the American Service chiefs. On the other hand, the task of convincing the British Government that it was useful and safe to entrust our most closely guarded secrets to the scientists and Armed Services of a then neutral country, with not a few anti-British elements in it, was not easy. But at last Tizard succeeded; and in September 1940, as the 'Blitz' on London started, the Tizard Mission, with Cockcroft as second in command, set out for the United States with the famous black box containing samples, blueprints and reports on nearly all important new British war devices. These included radar, fire control, under-water detection, aircraft turrets, Whittle's jet engine and, above all, a sample 9·1 cm. resonant cavity magnetron.

Within a few days American scientists had the magnetron working, to find it gave a thousand times the power formerly available. This remarkable invention, due to Randall and Boot working in Oliphant's laboratory at the University of Birmingham, was called by Watson Watt "a radically new and immensely powerful device which remains the heart of every modern radar equipment".

An assessment of the importance of this interchange of secret military information is given in James Phinney Baxter's book "Scientists Against Time", published in 1946 with a foreword by Vannevar Bush. The writer comments on the contents of the black box as "the most valuable cargo ever brought to our shores" and "the single most important element in reverse lease lend". He goes on: "In the early days of scientific interchange, the British gave more than they received". Later the debt was repaid many-fold; in particular, for example, by the superb centimetric anti-aircraft radar set *SCR*-584 and the proximity fuse which together led to such brilliant successes by Anti-Aircraft Command during the *V*.1 attack on England in 1944. The former set was a product of the famous Radiation Laboratory at the Massachusetts Institute of Technology, which was, in fact, founded as a result of a meeting of the Tizard Mission with American scientists in September 1940.

This imaginative act of trust, which Tizard and A. V. Hill first envisaged and finally forced through Whitehall, had immensely beneficial effects on the scientific aspects of the Allied war effort. Cockcroft reminds us that the Mission was magnificently organized by Tizard and that he had the inspiration to bring a mixed team of serving officers and scientists. For the first time our American friends heard civilian scientists discussing authoritatively the instruments of war and then heard the Service people following on with practical experience.

The Bombing Controversy

When Tizard returned to England in September 1940 on the completion of his American Mission, he worked full time at the Ministry of Aircraft Production and later became a member of the Air Council. The Air Defence Committee itself died a natural death, since an advisory committee of part-time members was not useful under fully mobilized war conditions.

There is little doubt that Tizard found less than satisfaction in what he could achieve during the years 1941 and 1942. In spite of his wide knowledge of the Government machine, he seems to have been genuinely disappointed to find that the Air Council rarely discussed strategy or tactics, but often minor administrative matters: he related that at one meeting of the Air Council the main business was the inspection of an exhibition of different designs of W.A.A.F. underwear! A deeper difficulty underlay the frustrations of this period. For it was not at all easy for a Service Ministry to incorporate a man as senior as Tizard in its taut, executive, war-time machine. On one hand he was too senior to do his own devilling among the files at the lower levels of the machine, where much of the real work of a department is done —to be sure, he was too impatient to have been very good at this—and on the other hand, he had too much self-respect to acquire influence by becoming a courtier. Tizard evidently felt that he was not wanted in Whitehall and so he accepted the presidency of Magdalen College, Oxford, where he remained, apart from some Government advisory work and several important visits abroad, until after the end of the War.

Shortly before he went to Oxford, Tizard became involved in a controversy about bombing policy which had far-reaching consequences. The interest of this story is not only its importance at the time, but also that it concerned problems of the theory and practice of bombing which, now with the advent of nuclear weapons, is giving rise to so much deep thought, subtle analysis and high controversy, carried on not least by members of the Institute for Strategic Studies.

As I remember it, what happened was this. In the early spring of 1942 the Prime Minister was extremely anxious that everything possible should be done by Bomber Command to help the hard-pressed Soviet armies at Stalingrad. About April a Cabinet paper (which was known to have been written in Lord Cherwell's office, Cherwell then being Paymaster-General and the Prime Minister's scientific adviser) was issued on the probable effect on Germany of the British bombing offensive over the next eighteen months, that is, until the early autumn of 1943. The paper laid down the policy of directing the bombing offensive primarily against the German working-class housing—middle-class housing was too spread out to be a good target and factories or military installations were too difficult to find and hit. So far as my memory goes, the paper claimed that it should be possible within the stated period to destroy 50 per cent of all houses in all towns of more than 50,000 population in Germany, if Britain concentrated all her efforts on the production of bombers and used them for this purpose. Tizard studied this paper in detail and concluded that the estimate of the number of houses likely to be destroyed in the next eighteen months was five times too high. At that time I was director of Operational Research at the Admiralty, and I was also asked to comment on the Cabinet paper. I came independently essentially to the same conclusion as Tizard—I think I estimated the error as six-fold. The main mistake made in the Cabinet paper was to assume that all bombers which would be delivered from the factories in the next eighteen months would in the same period have dropped all their bombs on Germany. The year or more from the completion of a bomber to the completion of its average operational life of twenty sorties had not been fully allowed for. The bombing survey after the War showed that the number of houses actually destroyed in the assigned period was only one-tenth of the estimate in the Cabinet paper: this agreed rather closely with Tizard's and my estimates, allowing for reduced numbers of bombers actually supplied to Bomber Command.

By this time a certain allergy to arithmetic was spreading in Whitehall, and our numerical forebodings went unheeded: the Air Ministry agreed with the Cabinet Office paper, and the policy of dehousing the German working-class population, with the object of lowering its morale and will to fight, became a major part of the British war effort.

The story goes that at that time in the Air Ministry it was said of anyone who added two and two together to make four, "He is not to be trusted; he has been talking to Tizard and Blackett". Less agreeable stories circulated: that anyone who made such calculations must be a defeatist.

So far as I know, Tizard never wrote anything of this period and spoke but sparingly; but he did comment after the War in his Royal United Service Institution lecture on the theory and practice of aerial bombing. "Experience has shown that a nation, with toughness, stamina and a will to live and work, can stand far more punishment in the form of bombardment of cities and homes than most people thought possible before the trial. No one thinks now that it would have been possible to defeat Germany by bombing alone. The actual effort in man-power and resources that was expended in bombing Germany was greater than the value in man-power of the damage caused. . . ."

If only Tizard's Offence Committee had succeeded as well as his Defence Committee, and if as a result a strong and trusted operational research section had been earlier established at Bomber Command, I think it likely that the numerical error on which the area bombing campaign was initiated would not have been made and that great advantage to the war effort would have resulted.

Whether or no this bombing controversy in 1942 was the decisive factor, there is little doubt that at that time there was not room enough at the top in Whitehall for both Tizard and Cherwell. The incompatibility of these two brilliant men, and one-time intimate friends, proved a calamity to the nation.

Too much, however, must not be made of personal factors, strong as these no doubt were. For the entry of academic scientists into fields of military strategy and tactics brings to them responsibilities for advising on courses of action on which the survival of one's country—or, to-day, in an age of nuclear weapons, the survival of civilization—may depend. So real differences of technical judgment become allied to differences of temperament and lead to lasting and often bitter struggles. The war-time controversy on bombing policy with conventional explosives and the strains that it engendered in Whitehall were but a minor foretaste of the still more bitter controversy, particularly in the United States, engendered by atomic weapons, which has left such a trail of personal antagonisms behind it.

Tizard in Whitehall, 1946–52

The result of the 1945 General Election with the consequent return of Cherwell to Oxford opened the way for Tizard to return to Whitehall. The opportunity soon presented itself, for in 1946 the new Government, headed by our President, Lord Attlee, invited him to become chairman of two new high-level advisory bodies, the Defence Research Policy Committee and the Advisory Council on Scientific Policy. Widespread acclaim from both scientists and military greeted both the formation of these bodies and the choice of Tizard to head them. Thus Tizard, for the third and last time, became a full-time Civil servant. What he achieved in the six years to his retirement in 1952 was by no means the least of his service to the nation, for there is no doubt that a great part of the credit for the growth to maturity of these two committees must go to him.

These last six years of his active life were in a real sense the fulfilment of his quarter-of-a-century-old belief in the importance to the life and prosperity of Great Britain of a close relationship between the administrative and scientific worlds, a belief which was one of the factors which led him in 1920 to forsake an academic for a Civil Service career.

It would probably be generally agreed that the Defence Research Policy Committee has proved a more effective instrument than the Advisory Council on Scientific Policy. This is certainly mainly due to the much narrower and administratively well-defined field of its activity. The executive authority residing in the Defence Ministry and the Chiefs of Staff, together with the related financial power of the Supply Ministries, gives them almost complete control of all defence matters, whether in the Government or in industry. So any advice from the Defence Research Policy Committee, on which these Government bodies are represented, is likely to be relevant and acted upon. Some of those who were intimately concerned with the working of the Committee hold that Tizard moulded it into the finest organization for co-ordinating the scientific and technical aspects of war policy which has ever existed in the Western world. During his time as chairman, from 1946 until 1952, Tizard's influence was exercised over a wide range of important and complex problems, including those arising from atomic weapons, super-sonic fighters, V-bombers and guided missiles. He shared much of the responsibility for developing the rocket range at Woomera, and when some Australians were worried that it would cost them a lot of money and perhaps no one would use it, he told them not to worry as it would attract work and men as a magnet attracts iron filings. A good example of his flair for the important practical action arose out of a discussion concerning the rocket and guided missile programme. After years of intricate debate on what the research and development programme should be, when a practical plan was eventually hammered out, Tizard ruled that the implementation of the programme should be carefully watched but that there should be no alteration or even discussion of the basic programme for two years. This ruling is reminiscent of his advice to fishermen: "Don't waste time changing flies and always know what the fishes are doing".

In his Haldane Memorial Lecture at Birkbeck College in 1955, Tizard referred to the creation of the Defence Policy Research Committee thus: "It was a revolution in organization. It was not until a short time before the Second World War started that scientists began to exercise an influence on the tactical use of weapons and later on strategy. I believe I can truthfully say that the very idea that they should interfere in such matters was repugnant to senior officers twenty years ago. It was the experience of war that caused the revolution and the appointment of the new Committee, far from being resisted by the Chiefs of Staff, was, in fact, initiated by them". "The Chairman . . . has full access to all relevant information, and attends the meetings of the Chiefs of Staff Committees not only when he is specially asked to do so but whenever he judges that his presence will be useful. No major recommendation on Defence Policy is made by the Chiefs of Staff without his knowledge and assistance".

The role of the Advisory Council on Scientific Policy, on the other hand, was much more difficult to define. Its advisory activities ranged over a wide field, including scientific and technological education and man-power, the organization of Government science and indirectly the efficiency of research and development in private industry. Taking into account the rigid autonomy of Government Departments and the privacy of private enterprise, the Advisory Council, with neither money nor executive authority, had from the beginning, and has still, a difficult task. Perhaps its main success has been in the field of scientific and technical man-power. Its relative lack of impact on the national life is not to be attributed to lack of ability of Tizard, but to the essential difficulty of injecting a small degree of direction into a social system where outside a few fields such as education and defence the word planning is not seldom used as a term of ridicule. These difficulties are currently receiving much public attention, stimulated by the vast scientific and technological power of the United States, by the much faster industrial growth of some of our European competitors and by the massive technological and economic advance of the highly directed economy of the Soviet countries. Here are problems galore for Tizard's successors on the Advisory Council on Scientific Policy to solve.

The changes that have taken place in the world of military science in the past twenty-five years, that is, since Tizard's Air Defence Committee was formed, have indeed been immense. The revolution in weapons is, of course, the most obvious, and the ultimate origin of the other organizational and psychological changes. In the 1930's it was certainly important in Great Britain to bring into the defence field from academic life as many highly trained and critical minds as possible; now in 1960 the outburst of analytical thinking and writing on military subjects by scientists, lawyers, historians, psychologists and philosophers, and, of course, by retired generals, is becoming almost overwhelming and is one of the fundamental causes of the foundation of the Institute for Strategic Studies. No serving officer could possibly find the time to read all the current literature; those amateurs like myself who write on these matters have no time to read all that the other amateurs write. The flood is greatest in the United States, where many universities have their military or foreign policy research groups or institutes, where brilliant academic minds analyse and dissect our present Western military discontents and are by no means shy of ingenious solutions. Traditionally, Britain has been averse to thinking about war in between fighting wars; once they are over we tend to forget about them until the next time. Even to-day there are only two academic posts in our universities concerned with military studies. The Institute for Strategic Studies is attempting, and I think successfully, partially to fill this gap.

This huge expansion of thinking about military subjects is, of course, largely due to nuclear weapons, and is to be welcomed as a sensible response to a highly complex and dangerous situation. On the other hand, I cannot convince myself that the practical content of the response has everywhere proved adequate to the challenge. The intellectual level of much of this discussion is of the highest, so high that I find much of it very hard to understand, and I wonder sometimes whether it is all rooted in military and political reality. The policies recommended by many of these studies seem not always to have been felt through to actual potential action. I think the essential prerequisite of sound military advice is that the giver must convince himself that if he were responsible for action, he would himself act so. During the War, when the Operational Research Group at the Admiralty had proved intellectually to themselves that big convoys were safer than small ones, before we advised the Navy to make this major change, we had to decide whether we really believed in our own analysis. I personally convinced myself that I did, by the conviction that if I were to send my children across the Atlantic during the height of the U-boat attacks I would have sent them by a big rather than by a small convoy. I think that occasionally analogous personal tests of belief in one's own recipes may be useful in the study of nuclear war. Perhaps part of the fault has been the relative silence of some professional fighting men, often may be for good Service reasons.

What I feel is needed now is more effective analytic activity within the Armed Services by those senior officers who would have, in the event of war, the actual responsibility of waging it—and conceivably of pressing nuclear triggers. All generals will agree that atomic war is much too serious a matter to be left to professors.

Tizard the Man

History has shown that Wimperis's choice in 1934 of Tizard as chairman of the famous Air Defence Committee was a very wise one: he had just the right mixture of academic and military background to enable him to build a bridge between these two very distinct worlds. Son of a captain in the Navy, who had been navigator to the *Challenger* Expedition and later Assistant Hydrographer, and who was also a Fellow of the Royal Society, the young Tizard had also been destined for the Navy but had been rejected because of eyesight. This, however, did not prevent him from becoming a pilot in the Royal Flying Corps during the First World War, where he rose to the rank of lieutenant-colonel and was awarded the Air Force Cross. Previously to this he had taken both mathematics and chemistry at Oxford, had spent a year in Berlin with Nernst, and had made researches in both physical chemistry and physics. Early in 1917 he was put in charge of all experimental flying at Martlesham Heath and later in the year went to headquarters of the Ministry of Munitions. In his lecture to the Royal United Service Institution in 1946, Tizard, commenting on his experiences at Upavon as a young Royal Flying Corps pilot, wrote of the "absence of any sign of interest on the part of the War Office . . . in the scientific development of the new fighting arm . . . as for air fighting, the enemy called the tune and we danced to it". Thus his early experiences in the Royal Flying Corps must have fixed as firmly in his mind the danger to the nation of technological inferiority in war as my experience in the Navy did in mine.

There is a well-known story of his Martlesham time. Just as he was about to take off to test a new Sopwith Camel fighter, a formation of Gotha bombers approached London. Tizard had the untested guns loaded and intercepted the bombers on their return, only to find that his guns jammed immediately. So he joined the formation and made notes about the speed and performance of the Gothas, which information was badly needed. He then waved good-bye. His most important contribution during the First World War was the development of a hitherto non-existent system of performance testing, so that afterwards no new design went into production without proper testing.

After the War he returned to Oxford and to physical chemistry, but only for a short time, as in 1920 he became assistant secretary of the Department of Scientific and Industrial Research, and secretary in 1926. Then in 1929 he became rector of the Imperial College of Science and Technology, where he remained until 1942. In 1933, he was appointed chairman of the Aeronautical Research Committee and held the post for ten years. He was thus very knowledgeable about all aeronautical matters.

With such experience and such interests it is not surprising that Tizard exploited so brilliantly the opportunity which Wimperis afforded him by making him chairman of that "grand body", as Rowe once called it. Tizard knew the Government machine well enough to realize that all committees could not achieve such great things, and in his Haldane Lecture one finds a good example of that dry wit which all his friends remember as one of his most endearing characteristics and which we all mourn to have lost. In writing of the early thirties and of the gradual growth of a machinery for scientific advice to the Government, Tizard refers to one committee in the following words: "The Committee on tsetse fly control was still sitting in 1938 without any noticeable effect on the expectation of life of these pests".

Tizard's outstanding achievement in bringing civilian scientists and serving officers into such fruitful contact was based on personal qualities of a high order. Though fundamentally of a conservative temperament and a great admirer of the virtues of tradition in national life, he was a radical in technological matters, and approached new problems and possibilities with courage, enthusiasm and originality. It is true that he often followed up too many ideas at the same time and sometimes bewildered his colleagues by alteration of course induced by the almost gad-fly quickness of mind. One reason for this was his instant readiness to look at anyone's bright ideas and to see whether they could be made to work. It is these qualities which perhaps led to him being considered a poor administrator by some people—it is true that he would sometimes chase some hare for a few weeks and then switch his interest suddenly to some more profitable quarry. However, these intellectual escapades were seldom fruitless and were an essential part of his method of spot-lighting the really important problems. When he himself had sifted the ideas thrown up by his own exuberant technical and administrative imagination he was exceedingly practical.

Throughout our long friendship, which began in 1934 when I became a member of the Aeronautical Research Committee of which he was then chairman—and what an admirable chairman he was— I have never failed to find stimulus, entertainment and enlightenment from his company. Though sometimes a little irritable, he was essentially warm-hearted and very wise. Of the individuals who have influenced me by their personality, I think Tizard comes next to Rutherford. As has already been emphasized, he had a most unusual ability to establish immediate and mutually stimulating contact with anyone doing a job; he seemed as genuinely interested in talking to a college porter, an aircraftsman or a young scientist as to a crack pilot, a professor or an air marshal. A visit with Tizard to an experimental establishment was an exhilarating experience: he left behind him a newer awareness of the tasks and a new keenness to get results.

Along with the great encouragement he so often gave to the younger men in the Services and in academic life, and his gift for inspiring them with his own enthusiasm for getting things done, his flair for setting the cat among the official pigeons, and for ignoring the normal channels, made him not always popular with the upper hierarchy. His sharp incisive wit was often exercised at the expense of the complacent, the pompous and the incompetent—among these he undoubtedly made enemies—but I have never heard of it being used at the expense of the young, the vigorous or the keen. There is a story which shows his ready wit, dating from the meeting of the British Association in Canada before the War. Tizard and a colleague inadvertently crossed over into the United States near Niagara. When challenged by a policeman, and not having their passports with them, they produced their Association membership cards. When the policeman told them that "The American Government doesn't recognize British Science", the lightning reply came from Tizard, "Oh, that's all right, neither does the British Government". As Linstead, the rector of Imperial College, recently wrote, Tizard himself played a major part in making the crack less applicable to-day.

In his Haldane Lecture, Tizard pays the highest tribute to Lord Haldane for his achievements over four decades ago, in making official circles in Britain first conscious of the national implications of the scientific-technological revolution. In a sense Haldane was the first British Minister for Science: Tizard was his disciple and we to-day are his. I will conclude by quoting to you, as expressing most aptly what many of his intimate colleagues feel about Tizard, what he felt about Bertram Hopkinson, professor of engineering at Cambridge, and one of the outstanding pioneers in Great Britain of the application of science to war, and whose death in an aeroplane accident in 1918 was a real calamity. Tizard wrote: "He had not only the position, but the qualities, to command respect from soldiers and scientists alike: and those who served under him, and who have been able to do anything for the Services in later years, have owed our own capacity largely to his leadership and inspiration".

EXPERIMENTS TO TEST EINSTEIN'S PRINCIPLE OF EQUIVALENCE

On January 30, the last day of the annual meeting of the American Physical Society in New York, three papers describing experiments designed to test Einstein's principle of equivalence were read. The principle announced by Einstein in 1911 states that a system in a uniform gravitational field is completely equivalent to a uniformly accelerated system, both for mechanical and for all other processes. This was suggested by the experimental result, which was first obtained by Galileo and more accurately by Eotvös in 1891, that gravitational and inertial masses are the same. From this principle, Einstein concluded that the rate of clocks at points of low gravitational potential is slower than at points of high gravitational potential, and deduced that spectral lines emitted from the Sun should show a shift to the red when compared with those produced on the Earth. He further deduced that the velocity of light is not constant in a gravitational field, so that light rays become curved, and that in all cases, in addition to an inertial mass, a gravitational mass $m = E/c^2$ is to be ascribed to energy.

If light travels in a system which has a uniform acceleration f, then the apparent Doppler velocity after a distance h is fh/c. Using the principle of equivalence, this implies that in the Earth's gravitational field the change of frequency of light is given by $\delta\nu/\nu = gh/c^2$. Alternatively, we may consider a description in which the rate of clocks changes in the gravitational field. Then, for the frequencies of the photon at the two points, we have $\nu_1 \approx \nu_0 (1 - \varphi_1/c^2)$ and $\nu_2 \approx \nu_0 (1 - \varphi_2/c^2)$ and $\delta\nu/\nu = \delta\varphi/c^2$, where φ is the gravitational potential, and $\delta\varphi = gh$.

It is interesting to consider the effects in a rotating system. Let us consider a system which rotates with angular velocity ω. Then a clock which is at rest in this system will be slowed down by an amount which increases as the clock is moved away from the axis of rotation. The time dilatation is given by:

$$t = \frac{\tau}{\left(1 - \frac{\omega^2 r^2}{c^2}\right)^{1/2}} \approx \tau\left(1 + \frac{1}{2}\,\frac{\omega^2 r^2}{c^2}\right)$$

where r is the distance from the axis.

An observer rotating with the system will not regard this as a special relativistic effect, since the clock is at rest in his frame; but at the clock he will observe a field of force, which he can describe by a potential, equivalent to a gravitational potential. Writing $\varphi = -\frac{1}{2}\omega^2 r^2$, we again obtain the expression $\delta\nu/\nu = \delta\varphi/c^2$.

It will be noticed that both these effects are second order in $1/c$, and are therefore extremely small. The expected shift in frequency of light from the Sun is about two parts in 10^6, and in the Earth's gravitational field, the shift amounts to 10^{-18} per cm. In a rotating system the shift can be made larger, but still not much greater than 10^{-12}, this limit corresponding to the maximum strength of materials. Repeated attempts have been made to observe the red shift in light from the Sun or from stars, but there are too many interfering processes of which little is known for convincing results to be obtained.

The situation has been completely changed by a discovery made in 1958 by R. L. Mössbauer, relating to the emission of γ-rays by nuclei in solids. It is well known that the natural width of many nuclear γ-rays, given by $\hbar/\tau$, where τ is the life-time, is extremely narrow. For example, a half-life of 10^{-7} sec. corresponds to a width of 10^{-8} volt. In a line of 10 keV., this gives a relative width of about 10^{-12}. But, in general, it is not possible to utilize this extreme resolution, because when the γ-ray is emitted, the nucleus recoils and the resulting γ-ray energy is shifted by the Doppler effect. If the nucleus were perfectly free, this would shift the line by a fixed amount; but in a substance at a finite temperature there is a large number of possible recoil velocities, resulting in a widening of the line.

Mössbauer showed that in the case of γ-ray emission from nuclei in a crystal, some γ-rays are emitted in which the recoil is taken up by the whole crystal, and therefore with a line-width which is determined by the life-time of the nuclear state. The fraction of γ-rays so emitted is given by the Debye-Waller factor, and depends particularly on the energy of the γ-ray, the elastic constants of the crystal and the temperature. It follows that when such γ-rays fall on a crystal containing the same nuclei as the emitting nuclei, there is a high probability that they will be absorbed by a resonance process. Mössbauer's original work was done with γ-rays from iridium. In this case, at 80° K., 1 per cent of the γ-rays emitted are 'recoilless'. Mossbauer showed that a relative velocity of a few cm./sec. between the source and absorber introduced sufficient Doppler shift to destroy the resonance. In September 1959, it was shown independently at Harvard and Harwell that the nucleus iron-57 emitted γ-rays showing the Mössbauer effect to a much more favourable extent. The Debye–Waller factor is in this case 63 per cent even at room temperature, and the line-width corresponds to a Doppler velocity of 0·01 cm./sec. It was realized both at Harvard and Harwell that this was a particularly suitable nucleus to use in experiments on the red shift.

The first of the three papers before the American Physical Society was read by Prof. Pound of Harvard University, and described work by himself and Mr. Rebka. He first gave an introduction to the gravitational effects similar to that given above, and showed how the effect discovered by R. L. Mossbauer offered the opportunity of testing the gravitational shift. The apparatus consists of a 400-mc. source of iron-57 mounted on a piezo-electric transducer, which is itself mounted on a hydraulic device which can provide velocities of the order of 0·0001 cm./sec. for calibrating purposes. Two counting systems were used, one a sodium iodide crystal close to the source, the other a group of crystals to obtain a large area, operated at a vertical distance of about 75 ft. A plastic bag containing helium was placed in the space between the source and the distant counters to reduce the absorption of the 14 keV. γ-ray. The transducer was operated sinusoidally, and the counts from the two counting-channels were switched into two pairs of counting systems by mercury switches, so that the pulses obtained with the source moving up were counted separately from those obtained with the source moving down. A dead time was provided to eliminate counts obtained during the switch-over period. The source on its transducer and the large counter were interchanged at intervals so that the expected sign of the asymmetry was changed. Prof. Pound showed a diagram with the asymmetries measured in the two counters in a series of two-hour runs taken in the six days previous to the meeting. The magnitudes of the asymmetries in the two counters fluctuated by larger amounts than could be accounted for by statistical fluctuations, but if averages were taken over all the runs, the measured difference in asymmetry between the counters was of the right magnitude. Prof. Pound emphasized that these results are preliminary, and that the experiments are being continued.

The second paper was read by Dr. T. E. Cranshaw and described a similar experiment performed in the Nuclear Physics Division at Harwell in collaboration with Dr. J. P. Schiffer and Dr. A. B. Whitehead. In this experiment, a 30-mc. source was mounted on a moving-coil transducer also operated sinusoidally. A gramophone pick-up was placed so that the needle was moved by the rod holding the source, and the output from this pick-up enabled the movement of the source to be monitored continuously. No dead-time was provided, the argument being that if the change-over was made when the source was moving slowly, the measured asymmetry is insensitive to the exact instant of switchover. Only one counter, a proportional counter of 6 in. diameter filled to $\frac{1}{4}$ atm. with krypton was used. Krypton is a particularly suitable gas, because it has an absorption edge just below the 14-keV. line, and so a comparatively low pressure can still give a high efficiency. Two counting channels were used, one fed from the proportional counter, and one fed with pulses from a pulse generator, and both were switched simultaneously in phase with the velocity of the source. The counts from the pulse generator were used to correct the counts from the proportional counter for inequalities of the time intervals. The results from two runs of counting were given, the source being always above the counter with an evacuated tube separating the two. In each run, cycles of four operations, including reversing the phase of the driving current in the transducer, were performed so that each part of the counting apparatus was used to count all four sets of pulses. In this way asymmetries of the apparatus were balanced out. In the first run at 12·5 metres, 30 cycles of 8 hr. each were carried out, and the asymmetry obtained corresponded to a Doppler velocity of $3\cdot9 \times 10^{-5}$ cm./sec. In terms of the expected shift, this gives the result 0·96 ± 0·43. The error quoted is that given by statistical fluctuations, and a χ^2 test on the separate 8-hr. runs showed deviations not appreciably greater than could be expected from the statistics. The second run at 3 m., consisting of 8-hr. cycles, was performed as a somewhat redundant test to ensure that the cycling procedure did indeed eliminate systematic errors. The average of these runs was of the expected magnitude, but the fluctuations in the individual points were about twice as large as those expected from statistics. This was attributed to the effects of the increased counting rate with the source at such a short distance from the detector. These experiments will also be continued with a stronger source to obtain a more precise result.

The third paper was read by Dr. J. P. Schiffer, who is a visitor at Harwell on a Guggenheim Fellowship from the Argonne National Laboratory, and described an experiment also carried out at Harwell on a rotating system in collaboration with Drs. H. J. Hay, T. E. Cranshaw and P. A. Egelstaff. The apparatus consisted of a source of iron-57 deposited on an iron cylinder 0·8 cm. in diameter, clamped rigidly between two circular 'Dural' plates of 6 in. diameter. At a radius of 6·6 cm. near the circumference of the plates, a 'Perspex' strip was fixed carrying an iron-57 absorber. The whole system was rotated at speeds up to 500 cycles per sec., giving accelerations of 65,000 times terrestrial gravity. Any shift in the energy of the γ-rays would be observed as a decrease in their absorption, that is, by an increase in the counting rate. The observed change in counting rate as a function of angular velocity followed the variation predicted by the theory of relativity with approximately 10 per cent accuracy due to counting statistics.

The two types of experiment together constitute an illustration of the principle of equivalence. The first type is the only one involving real gravitational fields and this by itself constitutes a test of a prediction of this principle. The rotor experiment can be understood within the framework of special relativity alone. It is, however, the first experimental test of a relativistic effect in a rotating, and therefore accelerated, system of co-ordinates. Theoretical physicists are not completely agreed about the significance of this latter experiment.

OBITUARIES

Dr. Oliver E. Buckley

Dr. Oliver E. Buckley died on December 14. He will be remembered for many things in the science and technology of electricity. His early years were notable for researches on such diverse topics as the Hall effect, ionization manometers, magnetic materials and submarine cables. His later years were occupied with important government advisory committees and boards. In between came an outstanding but quietly accomplished achievement that will increase in stature as the years go by. This was his work in assuring that basic research will have a secure place in the industrial laboratories of the future. It was he who took over from Dr. F. B. Jewett, the first president of the Bell Telephone Laboratories, a group of scientists who had already given promise of what basic research could do for an industry. Dr. Buckley saw and appreciated this promise. It was he who protected this group from pressures to digress into development. It was he who made it into a recognized function of the Laboratories' activities. It was he who turned it over in mature form to his successor, Dr. Mervin J. Kelly, when he retired from the presidency of the Laboratories in 1951 and as chairman of the Board in 1952.

Dr. Buckley was born in Sloan, Iowa, in 1887. He received the B.S. degree from Grinnell College in 1909 and the Ph.D. from Cornell University in 1914. He immediately joined the Western Electric Company as a research physicist. He soon developed an ionization manometer which was an important tool in the early work on vacuum tubes. Taking an interest in new magnetic materials, he was quick to recognize possibilities in the use of permalloy to increase the speed of telegraph transmission on submarine cable. When perminvar came along, he envisaged a submarine cable capable of transmitting human speech. This project was carried far enough to show that it was quite practical from a technical point of view. The economics of the times determined its fate. Dr. Buckley's interest never flagged, however. In 1932 he started a group working on a multichannel system employing repeaters powered at relatively low voltage with current sent through the cable itself. While this project was never completed in the original form, the work done on it was basic to the cables that now are in operation carrying many conversations across the Atlantic, to Alaska, to Hawaii and soon across the entire Pacific.

When the Western Electric Company's engineering department became Bell Telephone Laboratories in 1925, he was appointed assistant director of research. In 1933 he became director of research and in 1936 executive vice-president. He served as president from 1940 until 1951 and as chairman of the Board until he retired in 1952. During this time many technical advances were made. These included the wave-guide, the transistor, information theory and applications including plastic cable sheaths, automatic message accounting, nation-wide dialing, and micro-wave relay networks.

In the course of his career, Dr. Buckley received many honours and served on a number of important committees. He was a member of the General Advisory Committee of the Atomic Energy Commission, 1948–54, was appointed by the President to be the first chairman of the Science Advisory Committee, and was a member of the National Inventors' Council. He received the Medal for Merit, the nation's highest civilian award, in recognition of his contribution during the Second World War. He was a Fellow of the American Physical Society, the American Association for the Advancement of Science, the Acoustical Society of America, the American Academy of Arts and Sciences, and the American Institute of Electrical Engineers, of which he was vice-president during 1946–48. He was a member of the U.S. National Academy of Sciences, the New York Academy of Sciences, the Franklin Institute, and the American Philosophical Society, of which he served as vice-president in 1954–55.

In the face of these and other achievements, honours and activities, Dr. Buckley retained his characteristic friendly enthusiasm and love for people. He knew a great many of them, and knew how to work with them. To-day, more and more, we see industrial laboratories engaged in basic research. A large share in promoting this belongs to Dr. Buckley. By example in his own laboratories, by logic and inspiring discussion on boards and in committee meetings, and by personal contacts he made people see the need for this type of research and the harvests to be reaped from its cultivation. He has sowed well. The reaping will increase with the years.

F. B. Llewellyn

Captain Guy Gardner

Had he lived a little longer, Captain Guy Gardner's name would have been better known to archæologists in Great Britain than can be the case before the important record, in book form, of his prolonged excavations at the great proto-historic site of Mapungubwe in the Transvaal is available. His death in Johannesburg on Christmas Eve, aged seventy-eight. emphasizes the evils of over-delay in publication, in this case beyond the author's control. For the work was done in six consecutive seasons between 1935 and 1940, and written up during and after the ensuing war years. Its speedy publication is surely now a duty imposed on academic bodies in the Union of South Africa with or without a Government subvention.

Gardner was not a professional archæologist, and, indeed, had his first taste of field-work with me in the Faiyum in 1927–28. But though farming in Natal had been his livelihood ever since he settled in South Africa as a young man, he had loved history and archæology, particularly classical, all his life ; and in the Graeco–Roman remains of my Faiyum concession he rejoiced in his introduction to the reality of the beloved. "The Desert Fayum", Chapter 31, contains his unaided report, illustrated by plans and by drawings of pottery which at the time were the first substantial groups known securely dated to the reign of Ptolemy II.

A more ambitious opportunity followed. The now-famous kopje site of Mapungubwe Hill, accidentally discovered in 1932, had been partially dug by the late Neville Jones and J. F. Schofield in 1934 ; it had disclosed an iron-age Bantu culture, rich in gold ornament, yet the work of predominantly non-negroid people. This presented unresolved archæological difficulties of interpretation and date manifest in the ensuing publication, "Mapungubwe: Ancient Bantu Civilization on the Limpopo".

Continued research was obviously imperative. General Smuts in a London meeting urged my acceptance of the task; but my reply was to the effect that, on Zimbabwe experience, I preferred passionless archæology. South Africa, I felt, should be encouraged to produce its own excavators. The choice fell on Guy Gardner, who devoted unreservedly his time and energies to six seasons of arduous work, with only occasional European help. Were it not for his letters home, and for his published presidential address to the South African Archæological Society in 1958, and articles in the *South African Archæological Bulletin*, little would be known of his results or his opinions upon them; and even so, obscurities abound for lack of detail. In bare outline we know of his examination of cemeteries and deeply piled middens at the foot of a kopje named Bambandyanalo adjacent to Mapungubwe Hill. The culture, characterized by fine pottery and unusual burial ceremonials, is not that of Jones's and Schofield's people on Mapungubwe, though both populations fall into the Boskopoid–Bush category of South African anatomists, which Gardner terms 'Proto-Hottentot'. His excavations, when published, will have the great advantage over the earlier ones in that carbon-14 samples will introduce fixed dates (within their own wide margins of uncertainty) both for the 'gold users' of the Hill and for the less opulent but more interesting people of Bambandyanalo, who may be at least a thousand years old.

Guy Gardner's meticulous methods of excavation and record, graphic as well as verbal, are a guarantee that a mine of hitherto unknown information awaits impatient readers of his *magnum opus* to be.

G. CATON THOMPSON

NEWS and VIEWS

Physiology at Bedford College, London :
Prof. Margaret Murray

THE retirement of Prof. Margaret Murray from the chair of physiology at Bedford College prematurely because of ill-health is a great misfortune to many. She has been associated with Bedford College for forty-two years, as a student when she gained first-class honours in physiology and as demonstrator and as lecturer in biochemistry until in 1947 when she became professor and head of the Department. More than anyone else she has been responsible for the steady progress of physiology for science students in London, and the University owes her much for her services. She has been not only a member of the Boards of Studies in Physiology, and of Biochemistry, but also served on the Board of the Faculty of Science and on innumerable special committees, to which she always gave most conscientious attention. She was chairman of the Special Advisory Board on Dietetics, Nutrition and Household Service for many years and was a member of the Committees of the Medical Research Council on Dental Diseases and on Goitre. She has been a member of the Committees of the Physiological and Biochemical Societies and on the Editorial Board of the *Journal of Physiology*. Her opinions, if sometimes dogmatic, were clear, unafraid, to the point and always respected. Prof. Murray has a wide field of interest on the biochemical side of physiology. Her researches have earned her a high reputation in the scientific world, for her painstaking accuracy is known to all. Her intercollegiate classes on "Blood" were a model of what such classes should be, involving as they did an enormous amount of preparation. In later years she has taken a special interest in the prevention of dental decay by fluorine and its possible hazards, and in the prevention of goitre in hot countries by the use of sodium iodate. In 1937 she was awarded the D.Sc. of the University and now she has been granted the title of professor emeritus.

Prof. W. F. Widdas

DR. W. F. WIDDAS, reader in physiology in King's College, London, has been appointed to succeed Prof. Murray. He qualified in medicine in Durham in 1938 and after a short time in practice volunteered for the Royal Army Medical Corps. He served with the British Expeditionary Force until Dunkirk and later held staff appointments at Northern Command and at the War Office with the rank of major. In 1947 he joined the staff of Prof. A. St. G. J. Mc. Huggett at St. Mary's Hospital Medical School, where he worked with a team on fœtal physiology and rapidly became senior lecturer. Dr. Widdas's special interest has been the physico-chemical aspect of physiology, with special reference to the transfer of substances across animal membranes, and he has made notable contributions in this field. He was awarded the Ph.D. (London) in 1953 for a study of the kinetics of glucose transfer into the red cells of adult and fœtal animals, and in 1958 the D.Sc. for his further researches. In 1955 he moved to King's College, where he became reader in 1956. There he has not only been a very active teacher of large classes of medical and science students but has also conducted a very popular intercollegiate course in cell permeability for the B.Sc. (special). He has continued his studies on the red cell and by a most novel method extended his work to cardial muscle, which he has shown loses water during contraction. It is of interest that Dr. Widdas is the twelfth member of the staff of the Department of Physiology of King's College to become a professor in recent years.

Scientific Department of the National Gallery :
Mr. F. I. G. Rawlins, C.B.E.

MR. F. I. G. RAWLINS, scientific adviser and deputy keeper at the National Gallery, will retire at the end of March after twenty-five years service. After graduating at Cambridge (Trinity College) and research at the University of Marburg, he held a number of posts at Cambridge where he was also engaged in research in infra-red spectroscopy. He was the first vice-president and secretary-general of the International Institute for the Conservation of Museum Objects, and is technical director of the Central Council for the Care of Churches and a member of the Cathedrals Advisory Committee. He was the first scientific adviser to the National Gallery, and from very small beginnings he has built up a department which has made notable contributions in its special field. Mr. Rawlins was responsible for the arrangements for the transport of the pictures from the Gallery at the outbreak of war and for providing them with a place of refuge in a quarry in Wales where they were stored under carefully controlled conditions of temperature and humidity. He was successful in securing a grant from the Nuffield Foundation for scholarships at the Gallery. The scholarships proved of such value that the Treasury has assumed responsibility for these posts. The research that has thus been initiated by him at the National Gallery and carried on under his direction may well lead to fundamental improvements in methods of conservation. Mr. Rawlins was made C.B.E. in this New Year Honours.

Mr. R. H. G. Thomson

MR. R. H. G. THOMSON, who succeeds Mr. Rawlins at the National Gallery, has been research chemist (senior scientific officer) there since 1955. Born in 1925, he was educated at Charterhouse and Magdalene College, Cambridge, where he obtained a first-class in both parts of the Natural Sciences Tripos. He stayed on to read English, before joining Dr. Charles Singer in the preparation of "A History of Technology" to which Mr. Thomson was himself a contributor. He is a *rapporteur* of the Scientific Laboratories Committee of the International Council of Museums, and presented a paper at its Copenhagen meeting in 1959 entitled "Picture Varnishes To-day". This aroused considerable interest, and marked substantial progress in a highly specialized field. It is a major theme for further fundamental research in the National Gallery Laboratory. Mr. Thomson has recently become editor of *Studies in Conservation* (the journal of the International Institute for Conservation of Historic and Artistic Works) which brings him into touch with a wide circle of investigators, both in Great Britain and abroad. He is assured of the best wishes of friends and colleagues as he enters upon his new responsibilities.

Geological Society of London Awards

THE following awards for 1960 of the Geological Society of London have been announced: *Wollaston Medal* to Prof. C. E. Tilley, professor of mineralogy and petrology in the University of Cambridge, for his distinguished researches in mineralogy and petrology especially with relation to metamorphism; *Murchison Medal* to Dr. A. G. MacGregor, formerly assistant director of H.M. Geological Survey (Scotland), for his work in vulcanology and petrology and problems of the metamorphic rocks in Scotland; *Lyell Medal* to Dr. Doris Reynolds for her work on the rocks of Northern Ireland and her contributions to petrogenesis; *Prestwich Medal* to Sir Vivian Fuchs in recognition of the geological work of the expeditions which he has led in many parts of the world; *Wollaston Fund* to Mr. M. A. Calver, of H.M. Geological Survey, for his work on faunas of the Coal Measures, especially of the North of England and the Midland Valley of Scotland; *Murchison Fund* to Dr. D. V. Ager, lecturer in palæontology in the Imperial College of Science and Technology, for his researches on brachiopods and on Mesozoic stratigraphy; a *moiety of the Lyell Fund* to Dr. J. D. Lawson, lecturer in geology in the University of Birmingham, for his work on the stratigraphy and palæontology of the Ludlow rocks of the Welsh Borderland; *another moiety of the Lyell Fund* to Dr. R. H. Cummings, lecturer in geology in the University of Glasgow, for his researches on the morphology and evolution of the Carboniferous Foraminifera.

British Scientific Attachés

IN a written reply to a question in the House of Commons on February 3 regarding scientific attachés, the Minister of Education, Sir David Eccles, as representing the Minister for Science, said that five scientific attachés are now attached to British embassies abroad. The attaché at Washington is accredited also as scientific adviser (civil) to the High Commissioner in Ottawa. The attaché at Paris is accredited also to Berne and carries out liaison duties in Italy and the Benelux countries. The attaché at Bonn is accredited also to Vienna. The attaché at Stockholm is accredited also to Copenhagen and Oslo, and carries out liaison duties in Finland. In addition, a scientific adviser to the High Commissioner for the United Kingdom is stationed in Delhi. Attachés or advisers are thus accredited to eleven United Kingdom embassies or High Commissioners' offices.

Appointment of Scientific Officers for United States Embassies

THE U.S. Department of State has announced the appointment of seven additional scientists for its science programme. Three of those appointed are assigned as science officers in New Delhi, Buenos Aires and Rio de Janeiro, four as deputy science officers in London, Stockholm, New Delhi and Tokyo. The men selected are: Earnest Watson, dean of the faculty, California Institute of Technology, as science officer for New Delhi; Neal Weber, professor of zoology, Swarthmore College, as science officer for Buenos Aires; Harry W. Wells, chairman, Upper Atmospheric Section, Carnegie Institution of Washington, as science officer for Rio de Janeiro; John B. Bateman, United States Army Chemical Corps, as deputy science officer for London; William Littlewood, United States Navy Hydrographic Office, as deputy science officer for Stockholm; David C. Rife, International Co-operation Administration Adviser to the Government of Thailand, and formerly professor of zoology, Ohio State University, as deputy science officer for New Delhi; and Marshall Crouch, professor of physics, Case Institute of Technology, as deputy science officer for Tokyo. This is the second series of appointments to be made for the science programme of the Department of State under Wallace R. Brode, science adviser to the Secretary of State. The first appointments assigned science officers to U.S. Embassies in London, Paris, Rome, Bonn, Stockholm and Tokyo (see *Nature*, 183, 15; 1959).

Anglo-American Space Research

QUESTIONED in the House of Commons on February 15 regarding the Government's future policy towards space research, the Minister of Aviation, Mr. Duncan Sandys, as representing the Minister for Science, said that the plans for Anglo-American co-operation referred to in the Prime Minister's statement of May 12 and of the Minister of Supply's statement of July 29 were developing satisfactorily and we were proceeding with the preparation of the instruments to be carried in the first satellite. Vertical soundings and experiments in the ionosphere were being carried out in co-operation with Canada and Australia and all Commonwealth countries had been invited to give suggestions on all aspects of the programme and were being kept fully informed of progress. Britain was also going ahead with design studies of the modifications which would be needed to allow Blue Streak and Black Knight to be used for launching satellites and meanwhile Britain would make any use she could of test firings to obtain further information about conditions in the upper atmosphere.

U.S. Planning Committee on Planetary Sciences

The Executive Committee of the American Geophysical Union of the National Academy of Sciences has formed a Planning Committee on Planetary Sciences. The purpose of the new committee will be to accommodate the increasing number of American Geophysical Union members engaged in planetary and space research by expanding the Union's activities in this field. The following committee officials are announced: Homer E. Newell, jun. (deputy director, Office of Space Flight Programmes, National Aeronautics and Space Administration) as chairman; Robert Jastrow (Theoretical Division, Goddard Space Flight Center) as secretary. Other members of the committee are Philip H. Abelson, Leroy R. Alldredge, J. W. Chamberlain, Thomas Gold, J. G. F. MacDonald, Hugh Odishaw, Allen Shapley, E. H. Vestine, Harry Wexler and Charles A. Whitten.

School Children in Africa

More than half the world's children are now in school. Unesco figures, collected over a three-year period, estimate that there are approximately 550,000,000 children aged 5–14 years in the world to-day, but only 300,000,000 of them are in school. During the early 1950's, the world passed the half-way mark in getting school-age children into classrooms. The enrolment figure was 48 per cent in 1950 and 55 per cent in 1954. Many countries to-day still show low enrolment figures, especially in Asia and Africa; but it is in these countries that enrolments are increasing the most. In the Belgian Congo, for example, the number of primary school pupils rose from 145,000 in 1930 to 1,060,000 a quarter of a century later (*South Afr. J. Sci.*, 55, No. 7; July 1959). Enrolment in Ghana rose from 55,000 in 1932 to 508,000 in 1954. Girls' education is no problem in Basutoland where the difficulty lies in getting more boys into school. Owing to the economic pattern of Basuto life, where boys are traditionally herdsmen, girls outnumber boys in class by two to one.

Contemporary Physics

Two numbers of the new journal, *Contemporary Physics*, have so far appeared, and there are excellent articles in both (Taylor and Francis, Ltd., 18 Red Lion Court, London, E.C.4. 27*s*. (4 dollars) per vol. of six parts; 5*s*. (75 cents) per part). The journal aims at interpretation and review—to maintain the highest level of scientific content, but at the same time to present the content in such a way that the young graduate, and the teacher needing a refresher course to bring him up to date with modern developments, may understand without undue difficulty. The editor has succeeded in obtaining first-rate authors to write articles on interesting and topical subjects, but generally the standard is rather high and the text too burdened with fearsome mathematics and frightening graphs. There are exceptions, of course, like the articles on skidding friction by Barbara Sabey, of the Road Research Laboratory, and on diamond by Prof. S. Tolansky; but the reader turning with expectation to Sir Harrie Massey's article on space research may well be put off by the fact that it contains no illustrations at all. It is conceivable that it will be the university teacher and the more advanced physicist who will spend many enjoyable hours reading *Contemporary Physics*. The article, "Molecular Beams", by Prof. O. R. Frisch, for example, is an excellent introductory survey to the subject which will neither dismay a postgraduate research physicist working in some other field of physics, nor give him the impression that the author is talking down to his reader.

Specific articles in both numbers are devoted to historical or educational aspects of physics. In No. 1 (October 1959), Dr. C. Kellner discusses Alexander von Humboldt and the organization of international collaboration in geophysical research; Mr. H. V. Beck, the selection and design of experiments for alternating current teaching; and in No. 2 (December 1959), F. Lester describes a course in the physical sciences for teachers in training; Sir John Cockcroft, the newly founded Churchill College; and L. R. B. Elton the vexed question of a clearing-house to help students to find admittance to honours courses in physics. *Contemporary Physics* deserves to do well; perhaps, without departing too much from its initial standard, its content could be made more appealing in form and less suggestive of another learned society journal, so that it may reach the wider public for which it is intended and which it richly deserves.

Botanica Marina

Scientific periodicals are already so numerous that the appearance of a new one inevitably arouses misgivings. There does, however, seem to be a very good reason for the birth of *Botanica Marina*, the first number of which has recently appeared (Cram, de Gruyter and Co., Hamburg, 1959). As Prof. Drescher-Kaden points out in the introduction, classical botany has for hundreds of years been essentially *Botanica Terrestris*, but recently both planktonic and benthic marine algae have been attracting more attention than formerly. Their intrinsic interest is great and their practical importance large and increasing, so it is obviously desirable to have a journal for the publication of work on them. The editorial committee, which is truly international, must inspire faith in the future of this journal, while the contents of the first part give an indication of the range of studies to be included—cell physiology, chemistry, statistical ecology and what might be called 'straight phycology'.

It would be interesting if in some future number we could be given an account of the debt botanists owe to the work of zoologists and chemists in the investigation of marine phytoplankton. It must be considerable. *Botanica Marina* looks like becoming an essential periodical for every library with marine interests and a useful one for such others as can afford it.

Technological Education and the Nuffield Foundation

The Nuffield Foundation has made an imaginative and constructive approach to senior colleges of technology which should do much to raise the standards of technological education in Great Britain. In a letter to the principals of those colleges which provide advanced sandwich courses, the director, Mr. Leslie Farrer-Brown, has indicated that the Foundation would be prepared to consider any requests for financial help which would lead to improvement in the quality of technological education provided by the colleges. The Foundation in no way seeks to limit the way in which senior colleges of technology will develop and hopes that each will grow in a manner in which it can best serve the needs of industry. As education for technology must be given parity in technical institutions and in industry, there is room for considerable experiment about the ways in which this should be organized. So, too, with the teaching methods which have yet to be evolved. Among a number of tentative proposals, Farrer-Brown indicates that "perhaps, in suitable cases, the attainment and maintenance of high standards of teaching and the complementary training in industry, might be fostered if teachers of their colleges and their associated educational staffs in industry had the opportunity to study educational methods at technological institutions overseas". In the first place principals have been invited to submit informal proposals.

Leverhulme Trust

THE second report of the Leverhulme Trustees classifies the awards made during the first twenty-five years of the activities of the Leverhulme Trust Fund (The Leverhulme Trust. Analysis of Grants 1932–1955: Second Report. Pp. 18. London: The Leverhulme Trust, 1959). Of the total of £854,358, £179,400 was awarded to universities and centres of higher education; £84,000 to learned societies, research institutions, etc.; £132,700 to schools; £3,600 to archæology; £54,000 to the arts; £28,300 to architecture and town planning; £115,300 to medical research; £58,600 to trade charities; £26,400 to trade educational grants; £40,800 to miscellaneous grants, with £131,258 on the Advisory Committee, individual research awards and grants. No capital grants or contributions are made to appeals of a general nature. Long-term grants are, as a rule, excluded, and broadly speaking the Fund goes mainly to the furtherance of research in the universities, teaching hospitals and other centres of higher education, the Trustees' primary concern being to foster new ideas which may lack support from other sources.

Scientific Research in Schools

THE Committee on Scientific Research in Schools which was established by the Council of the Royal Society on March 7, 1957, reports that interest shown by schools in undertaking research projects has increased and all the research projects originally supported by Shell Research, Ltd., have now been transferred to the Committee. There are now forty-eight schools undertaking scientific research; some of the schools have more than one project under way and a total of fifty-seven separate research projects are now being administered compared with twenty-five projects last year. Various requests for advice have also been received from another two schools and these are under consideration. During the year a sum of more than £2,000 has been granted to those carrying out research. The Council of the Royal Society has provided a sum of £2,000 and Shell Research, Ltd., have given an additional £127 10*s*. in addition to their support of research in two schools. A scheme has also been arranged with the Director of the National Physical Laboratory, whereby, during the summer holidays, schoolmasters selected by the Science Masters' Association can visit the Laboratory and carry out some scientific work there. All research projects with which the Committee is dealing are carried out with the specialist advice and assistance of Fellows of the Royal Society and by others who have agreed to act as advisers. The Committee has been stimulated by the continued and growing response to its scheme and looks forward both to receiving further requests from schoolmasters and schoolmistresses and to the continued support of the Fellows of the Royal Society and others in acting as advisers and assistants in the extension of its activities. This enterprising scheme should do much to raise the standard of science teaching in schools.

The Geological Survey of Great Britain

THE Summary of Progress of the Geological Survey and Museum for 1958 records much work in the field and offices. With regret, however, it directs attention to the shortage of trained cartographical draughtsmen, who are so important in the preparation of the publication of geological maps. This regret is indeed shared by many who have to wait for such long periods to see the results of the field and subsequent reports that have been prepared by the geologists. Primary survey has been carried out in several areas and revision was continued mainly in areas of economic importance, particularly the coalfields. Statistics of mapping are given for the quinquennium. Exploratory boring is now an important part of the work of the Survey and the results of various geophysical methods are interesting. The Survey has continued as geological consultant to the United Kingdom Atomic Energy Authority, and an airborne radiometric survey of the remainder of Cornwall, much of Devon and part of Somerset has been undertaken. The Museum attracted nearly 390,000 visitors, and re-organization of the reserve mineral and economic collections and research upon them continued.

A Technique for Capturing Birds and Mammals

CAPTURING large numbers of wild birds and mammals for the purpose of marking the animals for ecological and behavioural studies is usually a difficult task. A paper by Ronald F. Labisky describes a technique which was found effective for capturing pheasants (*Phasianus colchicus*) and certain other animals by using bright lights at night to blind them temporarily ("Biological Notes", No. 40. Natural History Survey Division, University of Illinois). The capturing of pheasants by night-lighting, also called 'jack-lighting' or 'shining', has been employed in practical game management since the late 1920's. Oscar Johnson reported that workers in South Dakota captured about 10,000 pheasants during the winter of 1926–27, and 12,000 pheasants during the winter of 1929–30, by 'shining' roosting birds with motor-car headlights. More recently, workers in Idaho, South Dakota, Nebraska and California have employed night-lighting in capturing pheasants. In Illinois, one of the problems in pheasant research has been that of capturing and marking a large enough number of wild pheasants to permit investigations of behaviour, population dynamics and movements. While bait trapping of wild pheasants is successful in many States, it is difficult, or frequently impossible, in east-central Illinois during autumn and winter; this difficulty is probably the result of an abundant year-round food supply and moderate winter weather.

In order to facilitate the pheasant research programme in east-central Illinois, a mobile night-lighting rig was designed. The night-lighting apparatus was also found to be useful for observing and studying the behaviour of animals during the hours of night. This study technique is particularly valuable when many animals have been marked for individual recognition.

Stone-fruit Viruses

In serological and physical studies of stone-fruit viruses, R. S. Willison, M. Weintraub and J. H. Tremaine have reported that strain *Y*.4 of the cherry yellows virus was purified from cucumber by four methods (*Canadian J. Bot.*, 37, No. 6, 1157 ; 1959). These differed mainly at the clarification stage. Two of the methods, which are given in detail, yielded infective preparations. The virus was usually inactivated by freezing. Ultra-violet absorption spectrum analysis, and particle-size and sedimentation-rate determinations, supported by infectivity tests, indicated that, in these infective preparations, the virus replaced most if not all of the components found in comparable extracts from healthy sources. The agar-gel diffusion technique was used for precipitin tests. Virus antigen from cucumber sources reacted with homologous antiserum or with antiserum derived from infected cherry petals and vice versa.

Letters written by Frédéric or Irène Joliot-Curie

P. Biquard, writing on behalf of the Association Frédéric et Irène Joliot-Curie, Institut du Radium, 11 rue Pierre-Curie, Paris 5e, asks if readers of *Nature* possessing letters written by Frédéric or Irène Joliot-Curie would inform him. It is one of the aims of this Association to publish such correspondence, and it would like to receive such letters, or photocopies. The letters will only be published if their owners give the necessary authorization.

Classical Languages in Oxford Entrance Requirements

Congregation at Oxford has approved a scheme proposed by the Committee for Admission to the University for new entrance requirements. The position of Latin and Greek was the topic of widest interest in the new proposals, under which Latin would no longer be essential. The Committee for Admission recommended exemption from Latin for those who have a pass at Advanced Level in a General Certificate of Education examination or a college award in mathematics or science. This proposal was accepted, and a statute embodying the decision will be brought before Congregation next term. To become effective, the statute will require a two-thirds majority.

Colombo Plan Appointments

In a written answer in the House of Commons on February 12, the Minister of State for Commonwealth Relations, Mr. R. Thompson, stated that in consultation with the Government of India, the United Kingdom Government is arranging to recruit and provide, under the Technical Co-operation Scheme of the Colombo Plan, ten members of the professorial staff of the College of Engineering and Technology in the University of New Delhi, and two science workshop supervisors. It is intended that the professorial appointments should be for average periods of five years.

Announcements

Sir Harry Melville, secretary of the Department of Scientific and Industrial Research, will formally open the new laboratories of the Coil Spring Federation Research Organization in Sheffield on March 24 (see *Nature*, 184, 777 ; 1959).

The twenty-fourth meeting of the European Federation of Chemical Engineering will take the form of an International Symposium on Distillation, which will be held in Brighton during May 4–6. Further information can be obtained from the Institution of Chemical Engineers, 16 Belgrave Square, London, S.W.1.

Under the auspices of the Laboratory Animals Centre, a symposium on the Provision of Animals for Cancer Research will be held at the Royal Society of Medicine on May 23. Further information can be obtained from the Secretary, Laboratory Animals Centre, Medical Research Council Laboratories, Woodmansterne Road, Carshalton, Surrey.

The Department of Mechanical, Civil and Chemical Engineering, Royal College of Science and Technology, Glasgow, is organizing a symposium on Nuclear Reactor Containment Buildings and Pressure Vessels during May 17–20. Further information can be obtained from the Secretary of the Royal College of Science and Technology, Glasgow, C.1.

The Royal Microscopical Society is arranging a two-day meeting in conjunction with the Electron Microscopy Group of the Institute of Physics, to be held in Leeds on March 31 and April 1, to discuss "Co-ordination of Light and Electron Microscopy". Application forms can be obtained from the Secretary, Royal Microscopical Society, Tavistock House South, Tavistock Square, London, W.C.1.

The seventh international congress of the European Ceramic Association is to be held in London during May 23–28. The purpose of the conference is to establish opportunities for the discussion of common interests and problems between specialists from all parts of western Europe. Further information can be obtained from the organizing secretary, Mr. H. O. Cox, 36 Victoria Street, London, S.W.1.

The Chemical Society, the Institute of Petroleum, the Royal Institute of Chemistry and the Society of Chemical Industry are jointly organizing a symposium to be held in the Chemistry Lecture Theatre, the University of Manchester, on March 24, on the Industrial Chemistry of the Lower Olefines. Further information can be obtained from Dr. P. J. King, Department of Chemical Engineering, Manchester College of Science and Technology, Sackville Street, Manchester 1.

Dr. Marie Boas's book "Robert Boyle and Seventeenth Century Chemistry" (Cambridge University Press, 30*s*. net ; see *Nature*, 183, 850 ; 1959) has been awarded the Pfizer Prize of the History of Science Society for the best book on the history of science by an American author published in 1958. "The Rotation of the Earth", by Prof. W. Munk and Dr. G. J. F. MacDonald of the University of California, has been awarded the Monograph Prize of 1959 of the American Academy of Arts and Sciences for a work on a physical or biological subject. This book, a Cambridge Monograph on Mechanics and Applied Mathematics, will be published by the Cambridge University Press this autumn.

DEPARTMENT OF CHEMICAL TECHNOLOGY, UNIVERSITY OF BOMBAY

THE Department of Chemical Technology of the University of Bombay has just celebrated its silver jubilee, and it is thus an opportune time to review briefly the development of this Department and its impact on Indian industries. Its foundation may be largely attributed to the vision and enthusiasm of Sir M. Visvesvaraya, who, as chairman of a Government of India committee, recommended as long ago as 1921 that a faculty of technology be instituted in the University of Bombay and that a College of Technology be established in Bombay City. It is probable that the practical difficulties associated with so large a scheme delayed its fulfilment, for it was not until 1930 that the matter was raised again in a more modest way, with the result that in 1934 the University started two new two-year courses, one in textile chemistry and the other in chemical engineering, to each of which twenty chemistry graduates might be admitted annually. The choice of subjects was a wise one: chemical engineering for its general applicability to all industries, and textile chemistry because of its value to the immense cotton industry of the Bombay Presidency. The first graduates were well received by industry, and the demand soon became far greater than the supply.

Moreover, many private individuals and associations, seeing that this was the beginning of a new era in industrial development, made handsome contributions for the endowment of chairs and readerships, or for the establishment and equipment of specialized laboratories. These have amounted so far to £280,000, and in conjunction with large government grants have made possible the erection on a 14-acre site of a group of laboratories of the most modern type on a unit basis, which allows extension or subdivision with a minimum of disturbance. Special features are the large quantity of small-scale plant and high-class instruments intended mainly for research work. There are a well-equipped workshop and a spacious drawing office in which all students have to work, and the library contains about 8,000 modern technical works and more than 200 periodicals to which readers have free access.

The two sections with which the Department started were originally housed in part of the Royal Institute of Science, which gave little room for expansion; but as soon as the success of the project was assured, preparations were made to build the new laboratories and to add more sections to the Department. Starting in 1943 when the laboratories were ready, new branches were gradually added, and there are now seven two-year courses of study open to chemistry graduates which lead to the degree of B.Sc. (Tech.). These are textile chemistry, and the technology of pharmaceuticals and fine chemicals, food, intermediates and dyes, oils, fats and waxes, plastics, and pigments, paints and varnishes. Chemical engineering is now a four-year course, starting from intermediate, for which the degree of B.Chem.E. is awarded, and there is also a three-year degree course from intermediate in pharmacy. In addition, emphasis is laid on research and work for higher degrees, and there are now 125 postgraduate students out of a total of about 525. Members of the Department have published in all more than 700 scientific notes, articles and papers, mostly on experimental work conducted in the laboratories. The Department also acts as a test house for the textile industry and undertakes sampling, analysis, the investigation of technical difficulties and more comprehensive schemes of industrial research for outside bodies.

The number of students has increased in a remarkable manner. Starting with 109 admitted during the first five years, it rose to 380 ten years later, and during the past four years it has been 785. The proportion taking a degree is very high, more than 1,500 of the 1,700 admitted having been successful. These graduates are much sought after; up to the end of 1957, the last year for which detailed figures are available, 762 were engaged in the manufacturing industry out of a total of 1,316.

Unfortunately, this healthy expansion is threatened by circumstances which must already be a source of anxiety to the authorities—the almost world-wide problem of staff. In Bombay the chairs of textile chemistry, food technology and chemical engineering are all vacant, and in the last-mentioned section one readership is vacant and one lecturer is on study leave, leaving one reader and a temporary lecturer to deal with a four-year course to which forty-five or even more students are admitted annually. It is evident that adequate teaching of the wide range of subjects contained in the syllabus cannot be maintained without a large increase of staff. Other sections are suffering in the same way, although to a smaller extent, and the trouble has been mitigated slightly by members of the staff of other institutions, seventeen of whom are generously helping by giving part-time assistance. It would seem that a satisfactory state of affairs will not be reached until the Department's own graduates and those of similar establishments have increased in numbers and experience to such an extent that the small percentage who take up teaching (augmented perhaps by higher salaries) will be sufficient to provide an adequate staff.

The effect of the introduction of 1,500 trained scientists with an acquaintance with industrial conditions and a specialist knowledge of certain technical operations into the country, followed by more than 150 every year, cannot fail to exert a profound influence on the economy of Bombay and indeed of the whole of India. When it is considered that a large proportion of these men have, in addition, a research outlook which may lead to important improvements, it is difficult to form any estimate as to the changes which may result. It suffices to say that these changes can be only for the good and likely to give the utmost satisfaction to all who so wisely gave their time and their money to further the cause of technical education. H. E. WATSON

THE BRITISH COUNCIL

THE annual report of the British Council for 1958–59 includes a brief tribute to the late chairman, Sir David Kelly, the customary appendixes, particulars of university interchanges, courses and study tours, etc., arranged by the Council in the United Kingdom or overseas, exhibitions and publications, analysis of estimates and accounts, and an assessment by the director-general, Sir Paul Sinker, of the main tasks confronting the Council (The British Council. Annual Report 1958–59. Pp. vi+114+9 plates. London: British Council, 1959). Over the past five years, the Council's gross income, derived mainly from public funds, has almost exactly doubled, from £3 million to £6 million. Its work is carried out in about seventy countries, now some four-fifths in the developing areas of the world, especially in the Near and Middle East, South and South-East Asia and Africa, rather more than half of this being devoted to the recently independent countries of the Commonwealth and to Colonial territories, and the fifth, devoted to Europe, includes an important extension to the German Federal Republic.

Sir Paul Sinker emphasizes three tasks as of pre-eminent importance: educational work, especially but not exclusively in the teaching of English; the fostering of personal contacts between British and overseas people, especially between opposite numbers in the educational, scientific, professional and cultural fields; and helping to ensure that English reading matter is as widely available as possible in the countries with which the Council is concerned. In educational work he comments that the recruitment of British teachers for overseas posts has been a main point of growth during the past two years, and the Council has been concerned to ensure good salaries and living conditions, reasonable security and opportunity for obtaining a suitable job on return. All this has meant additional work for the Council's representatives overseas, and since 1957 these posts have been increased by twenty-five of an educational character. The filling of university posts has presented special difficulty. As regards personal contacts, besides some 40,000 overseas students in Britain, the Council looks after, every year, some 5,000 senior visitors, and Sir Paul directs attention to the proportionate increase in the number of visitors for scientific and technical purposes and to the very considerable increase in the Council's responsibilities for administration of the United Kingdom fellowships and similar schemes on behalf of the Government and other authorities. More than 2,000 Fellows and Scholars a year are cared for under various schemes, and the Council is also responsible for organizing a smaller but important outward flow of specialist tours from the United Kingdom. On the printed word, Sir Paul Sinker stresses the key importance of the library in a British Council centre and the advances on a wide front which have been made possible by the Government announcement on June 22, 1959, regarding the export of British books, etc. Finally, he refers briefly to the opportunities which arise as Colonial territories attain independence and also to those offered by educational television.

The general survey of the year notes that the Council's responsibilities are likely to be increased as a result of the Commonwealth Educational Conference in July 1959, as it is probable that the Council will be asked to assist in implementing the main recommendations of the Conference. About half the £1·5 million by which the Council's grants have been increased since 1957 has been used to implement the decisions announced in the first White Paper regarding the teaching of English overseas. Eighty teachers have been recruited for specific posts, mainly in India, Pakistan, South East Asia, the Middle East and Africa, and almost double this number should be recruited in 1959–60 and a further seventy teachers supplied by the provision of financial assistance to schools. Besides 100 scholarships awarded to bring overseas teachers to the United Kingdom for training, a further 68 are being awarded in 1959–60, and the Council has been encouraged by the growing interest of British universities in these problems. Qualified lecturers and tutors are needed, however, at summer schools for teachers of English both at home and abroad, and a further problem is the provision of material for English language teaching.

Agreement was reached with the government authorities of several countries, notably Pakistan, to extend full Council services to their students in Britain, and during the year 7,500 overseas students were met on first arrival. Some 101 specialist tours, advisory visits and delegations, included one to Poland by Prof. J. N. Davidson, the first of several visits of biochemists arranged at the invitation of the Polish Academy of Sciences, and another to India by Sir Harry Platt. Prof. R. M. Kenedi, of the Royal College of Science and Technology, Glasgow, was invited to visit Lima Engineering University to lecture, assist in organizing programmes of studies and advise on purchase of equipment, and a British engineering library has been opened in the Institute of Higher Studies, Buenos Aires. Under the Commonwealth Scheme of university interchange, awards were made to permit ten short visits for consultation and lectures and 47 travel grants were made to university teachers and postgraduate research workers: under the foreign scheme 121 short visits and three longer visits were arranged, besides 57 visits under the younger research workers interchange scheme. Of 5,153 overseas visitors in the United Kingdom under the auspices of the British Council, 996 were in science and technology, 1,255 in education, 1,152 in social science, and 974 in medicine, 739 coming from the Middle East, 562 from South-East Asia and the Far East, 347 from Latin America, 1,232 from Central and East Europe, and 953 from West Europe. Of the 7,487 students met on arrival, 459 were found permanent accommodation in Council residences, 310 in university halls of residence and hostels, and 3,215 in lodgings. Transit accommodation on first arrival was arranged for 1,877 in Council residences and in lodgings for 1,178, while temporary accommodation was arranged for another 1,354 in Council residences and 4,686 in lodgings, and 9,749 students enrolled at Council centres, 2,353 attending vacation courses of 7–15 days, 1,340 week-end courses, and 8,778 study visits to factories, museums, etc.

CYCLICAL ACTIVITY IN ENDOCRINE SYSTEMS

COMPARED with members of most learned bodies, Fellows of the Zoological Society of London have always been well served—more so than many have realized—in regard to the collections, the library, and the gastronomic and other facilities that they are privileged to enjoy. Additionally, in recent months, there has begun a most welcome series of one-day symposia which will in future take the place of a proportion of the ordinary scientific meetings of the Society. These symposia are not too narrowly specialist, and they are open to all zoologists whether Fellows of the Society or not.

The second such symposium, on "Cyclical Activity in Endocrine Systems", was convened by Prof. E. J. W. Barrington, and held on December 8.

The first two papers dealt with the cyclical activity of the fish thyroid. Dr. A. J. Matty (Nottingham) pointed out that although recently a number of reports have indicated a seasonal change in the thyroid, most have been derived from histological data. Only in one species has hormonal iodine been determined. Variation from species to species both in degree and time of thyroid activity made few generalizations possible, although it is possible in some instances to correlate a seasonal thyroid change with locomotory and migratory changes. Some fish appear to have a more active thyroid during spawning, and Dr. Matty suggested that, as the gland does not seem directly to stimulate gametogenesis, the relationship is due to the influence of the thyroid on protein metabolism, for example, on gonad growth or the development of viviparous young. The thyroid in fish has been shown to influence growth, metamorphosis and integument development and, as current researches have demonstrated that nitrogen metabolism is influenced by thyroxine, it was suggested that a principal role of the piscean thyroid is the control of protein and nucleoprotein metabolism.

Dr. D. R. Swift (Windermere) made a general survey of the external factors which could affect the thyroid and its demonstrated cyclical activity. He emphasized that we do not know what the epithelial cell height and uptake and loss of radioiodine mean in terms of actual activity of the gland and that it was difficult therefore to compare the results obtained by workers using different methods. Dr. Swift suggested that the thyroid undergoes two periods of high activity, one period coinciding with the maturation of the gonads, with which it may be in fact concerned. The second period of high activity occurs as part of what is called the basic cycle of thyroid activity in these animals. This activity of the gland appears to be inversely proportional to the water temperature. It was suggested that temperature plays a major part in the control of the thyroid, but that the length of the photoperiod may influence the gland at low temperatures. It was stressed that it is the change in the environment which is important. Obviously, in Nature, the fish never experience a constant one.

Dr. P. G. W. J. van Oordt, a welcome visitor from Utrecht, is primarily interested in the Amphibia. He spoke of the influence of internal and external factors in the regulation of the anuran spermatogenetic cycle. He concluded that spermatogenesis depends on two so-called final factors, first (as would be expected) the gonadotrophic activity of the pituitary, and secondly, the sensitivity of the germinal epithelium to gonadotrophic hormone. Each such factor is influenced by one or more 'intermediate' factors. These include, for example, a gonadotrophin secretion-inducing agent produced by the preoptic nucleus of the hypothalamus. The male sex hormone is also influential. In Amphibia with a potentially continuous spermatogenetic cycle this activity is primarily regulated by the external temperature. This basic factor, together with the internal rhythm, determines the seasonal changes in the spermatogenetic activity of Anura with a discontinuous spermatogenetic cycle *sensu stricto*.

Dr. A. J. Marshall (London) next discussed cyclical phenomena and corresponding behavioural adaptations in relation to the environment in birds. While paying due regard to the importance of day-length changes as a regulatory factor, he remarked that if we viewed the avifauna of the world, light is important only in species for which it is important that it should be important. A whole range of widely unrelated species would be extinguished by natural forces if they were compelled to reproduce at any particular phase of the cycle of the Sun. In perennially lush areas, it is often biologically beneficial—and possible—for species to have more than one breeding season per year. There is a fascinating, as yet unwritten, story of the changes in behaviour that have gone hand in hand with the neural and endocrine changes dictated by the environment and natural selection.

The complexity of endocrine cycles in vertebrates was emphasized by Prof. E. J. W. Barrington, who gave illustrations from the work of his Nottingham group to show the difficulties encountered in attempting to demonstrate a one-to-one relationship between a particular cycle and a particular function. He concluded that an essential part of the study of such cycles must be the means by which they are coordinated and brought into relationship with the external environment. This involves, in particular, a study of the pituitary and its relationships with the central nervous system. The evolution of the trophic control exerted by the adenohypophysis is one aspect of such a study, and he discussed from this point of view the relationship which has recently been claimed to exist between the adenohypophysis and the endostyle in the ammocoete larva. Results obtained at Nottingham suggest that it is by no means clear that such a relationship is demonstrable on the present evidence. Finally, he considered the problem of the relationship between the hypothalamus and adenohypophysis in teleosts and gave evidence suggesting that (contrary to what has previously been supposed) the vascularization of a particular area of the floor of the infundibulum has at least some of the characteristics of a median eminence, and that glial secretory cells are found in the same area. Identifications of such areas in other fish, and a study of any cyclical variations which they may show, should shed much light on the regulation of endocrine cycles in the lower vertebrates.

Dr. G. W. Harris (London), who thoughtfully made it a condition of his appearance that he would not have to write a paper, dealt comprehensively with comparative aspects of the functional relationships of the hypothalamus and adenohypophysis. He paid a graceful tribute to the pioneer work of the late F. H. A. Marshall in the field of reproduction physiology.

The final two papers were concerned with invertebrates. Dr. M. J. Wells (Cambridge) gave an account of some of his work on the optic glands and the ovary of *Octopus* and described a hormonal system which regulates the onset of sexual maturity. In cephalopods, maturation of the gonad depends upon release of a protein secretion from the optic glands. These are in turn governed by an inhibitory nerve supply originating in the highest centres of the central nervous system. The optic glands can be activated (causing precocious sexual maturity) by severance of this nerve supply, or by peripheral blinding. 'Ripening' of the oviducts and oviducal glands is independent of ovarian maturation. The system is single-stage; the state of these secondary structures is not under the control of sex hormones. The brain-optic gland system of cephalopods has obvious analogues in chordates and arthropods; the factors determining the convergent evolution of mechanisms for delaying the onset of sexual maturity were discussed.

The final paper was by Dr. D. B. Carlisle (Plymouth) on moulting cycles in Crustacea. The act of moulting in arthropods, said Dr. Carlisle, must not be considered as an isolated event but as the most spectacular moment in a continuous cycle of metabolic activity. Each moulting cycle is basically like the one before it, and many of the stages have now been shown to be under hormonal control. Secretion of the 'moult inhibiting hormone' by the endocrine complex of the eye-stalk promotes the formation of new tissues and prevents the Y organ from secreting more than 'marginal' amounts of its hormone. Once this eye-stalk hormone ceases to be secreted the Y organ releases a single 'dose' of a moult-promoting hormone. This initiates the preparations for the moult which, once under way, are co-ordinated by a moult-accelerating hormone from the X organ. The amount of water taken in at the moult itself is regulated by a further eye-stalk hormone. Many other hormones act upon particular moults and modify them in some way, acting mainly upon the stage of proecdysis and making the succeeding moult in some way unique: the moult of puberty and the moult at which a female becomes furnished with the brooding characters are examples. In the same way that the originally similar segments of the vertebrate body have been progressively and uniquely modified (in, for example, the head) so the originally similar moults of arthropods have been modified, until we have what Dr. Carlisle called 'the startling difference' between the larval and imaginal moults of Lepidoptera.

Prof. J. Z. Young, who was chairman of the invertebrate session, enlarged upon a statement made by the final speaker concerning the complications of modern endocrinology. Prof. Young said that the presence of a multiplicity of hormones was the natural consequence of the fact that they were sent out, broadcast through the body and each needed to be addressed to a particular target. No such multiplicity of chemical mediators was necessary in the nervous system, where addresses were specified by connexions. The discovery of more and more distinct hormones was a sign of the maturity of the subject. Endocrinologists were learning to understand the code with which their complicated system operated.

The symposium concluded with a general discussion and a summary by Sir Solly Zuckerman. The papers will be published soon as one of the *Symposia of the Zoological Society of London*. A. J. MARSHALL

AERODYNAMIC CAPTURE OF PARTICLES

A SYMPOSIUM on this subject was held during January 13–14 in the laboratories of the British Coal Utilization Research Association at Leatherhead.

Although this might be thought to be a field of very limited appeal, yet, as evidenced by the wide interests of the fifty scientists present, the impingement of small particles carried in a stream of air and falling on to a solid surface placed alongside or in the way of the flow is a problem which concerns a number of industries, as well as having meteorological implications ranging from the icing of aircraft wings and motor-car windscreens to defence against microbiological warfare.

The wide scope of the applications of this study can be seen by looking through the list of titles offered at this symposium. In 'pure' meteorology one studies cloud formation and collision of raindrops, in applied meteorology the wash-out by rain of particulate matter, whether this be the product of industrial air pollution or of an atomic explosion. A number of cognate problems arise in the laying of mine dusts by water sprays. Then we have the impact of water drops or ice crystals on large moving surfaces such as aircraft wings or turbine blades; when both the obstacle and particles are on a smaller scale we have the action of the gas-mask filter (one of the earliest applications).

The coagulation of particles carried by a stream of air or water is, of course, of great interest and involves many applications where solid or liquid particles have to be transported from place to place, for example, in the industrial process of fluidization.

The basic theory of much of this work stems from Albrecht, who worked out in 1931 the proportion of particles carried by a stream of air which would be intercepted by a cylinder placed athwart the stream. The particles tend to follow the stream lines as they approach the cylinder, but their mass makes them continue in a forthright direction. If their resistance in the stream is given by Stokes's law, that is, direct proportionality to velocity and viscosity, their actual paths depend on this balance between inertia and viscosity in a parameter resembling a particle Reynolds number. This 'particle parameter' has been used continually in capture problems since (and deserves the attribution of Albrecht number).

The conference, opened by a short address of welcome from Dr. Idris Jones, director of research of the National Coal Board, was divided into three sessions. The first morning covered fundamental aspects, a number of developments of the Albrecht thesis, using modern mathematical devices and including other types of flow around the obstacle than the potential one (H. Herne). Prof. P. R. Owen had devoted a considerable study to the process by which a turbulent wind-stream deposits particles on the roof of a tunnel, while Dr. D. J. Brown had studied the behaviour of particles in the process of froth flotation. Dr. T. Gillespie, who had come from the United States to attend the symposium, described his interesting series of researches on the role of electric forces in collision processes.

The afternoon session was devoted to practical applications of capture techniques. Accounts were given of the deposition experiments on radioactive particles and gases carried out at the Atomic Energy Research Establishment (A. C. Chamberlain); on particulate filters—one of the earliest applications—at the Chemical Defence Experimental Establishment (R. G. Dorman); on fish-curing smokes at the Herring Industry's Research Station (W. W. Foster) and two applications in the aircraft industry, namely, impingement of water drops on a surface at supersonic speeds (D. C. Jenkins and J. D. Booker) and on turbine blades (D. L. Martlew).

In the final session the papers dealt with collisions of particles with rain-drops, and of drops with each other. The difficult calculations on the relative motions of particles of comparable size—when the flow pattern around each contestant must be known—had been made by Dr. L. M. Hocking; but other papers were primarily experimental. A long and careful series of experiments by W. Walton and A. Woolcock and less-extensive ones by Dr. R. G. Picknett involved the measurement of the pick-up by a single water drop on which small particles impacted. Finally, the effect of the efficiency of the pick-up process when the particles are wettable and can be engulfed or pass completely through the water drop was discussed both theoretically (by C. S. Pemberton) and experimentally (by B. Oakes).

At the conclusion of the third session, Mr. W. Walton (National Coal Board) thanked the staff of British Coal Utilization Research Association for offering the symposium the hospitality of its conference rooms and laboratories, the work in which the visitors were able to inspect before leaving.

Lively discussions followed the reading of the papers. The whole proceedings are to be published by Pergamon Press, Ltd. and should form an interesting volume in a field which has not been heretofore covered by a book.

E. G. RICHARDSON

THE SHUTTLE-BOX BEHAVIOUR OF ALBINO RATS DURING PROLONGED EXPOSURE TO MODERATE-LEVEL RADIATION

By DR. JOHN E. OVERALL*, DR. W. LYNN BROWN† and DR. LOREN C. LOGIE‡

The Radiobiological Laboratory, University of Texas, and the United States Air Force, Austin, Texas

THIS series of investigations was commenced in an effort to test conclusions reached by other investigators[1,2] that radiation is a 'noxious stimulus' capable of resulting in avoidance conditioning. In three independent attempts to reproduce 'spatial conditioned avoidance' at this Laboratory, no success was obtained. In each of these experiments, albino rats were on alternate days exposed to 1 r. per min. of X-radiation while confined in a black compartment. During subsequent test periods, the rats were given free access to black and white shuttle-box compartment. No significant avoidance of the black compartment was observed in any of the three experiments when the behaviour of the experimental subjects was compared with that of control subjects.

Although no 'conditioned avoidance' was observed n the initial experiments, it could not be concluded that rats are unable to perceive radiation. A more sensitive procedure would seem to be one that allows rats to choose between two shuttle-box compartments —one located in a radiation field and the other shielded from radiation by a lead screen. Because rats normally prefer the darker of two compartments, it was considered appropriate to use shuttle-boxes with one dark and one light compartment and to place the darker compartment in the exposed area. Dose-rates of 0, 1, 2 and 4 r. per min. were employed in this experiment. The results clearly indicated that the experimental animals spent less than a normal amount of time in the usually preferred darker compartment. It was concluded that the presence of radiation in a normally preferred surrounding results in reduced preference for that surrounding; however, no conclusion concerning the nature of the mechanism responsible for the change was possible. Did the rats perceive the radiation, or its immediate consequences, and associate it with the black compartment? Did physiological changes resulting from the radiation produce stimuli which simply overshadowed the normal preference for the dark compartment?

A new experiment was designed which was like the preceding one except that it involved three groups: (*a*) 'radiation experimental' with exposure in the darker compartment and no exposure in the lighter compartment; (*b*) 'non-radiation control' with no exposure in either compartment, and (*c*) 'radiation control' with exposure in both the lighter and darker compartments. The brightness contrast between the two compartments was systematically varied in five steps from black-white to black-black. Both male and female rats were used. It was reasoned that if the previously observed change in shuttle-box behaviour had resulted from the rats learning to discriminate between the exposed and non-exposed areas, then the 'radiation experimental' subjects should again evidence this change, but the 'radiation control' groups should behave no differently from the 'non-radiation controls'. On the other hand, if radiation-produced stimuli simply overshadowed the normal brightness preference, then both of the radiation groups should differ from the 'non-radiation controls' but not from each other. The results clearly favoured the latter alternative, and it was concluded that most of the change in preference for the normally preferred environment was the result of a generalized response to altered physiological state and did not result from the perception of radiation and the learning of an avoidance response. This type of change was significantly more pronounced among female rats. Although the results clearly indicated that the preponderance of the observed effect did not depend upon a perceptual-learning mechanism, the probable presence of such a mechanism was suggested by the results. The two rats in the 'radiation experimental' group which were placed in shuttle-boxes with two otherwise identical black compartments spent an average of only 19 per cent of the time in the exposed compartment. Using a pooled estimate of error derived from the complete results, this value was significantly below chance.

† Department of Psychology, University of Texas, Austin, Texas.

‡ Captain, U.S.A.F., School of Aviation Medicine, Brooks Air Force Base, Texas.

An experiment was designed using only shuttle-boxes with two identical black compartments. Both male and female rats were used and, in an effort to identify the mechanism responsible for the previously noted sex differences, both male and female gonadectomized rats were also included. For half the rats the left-hand compartment was shielded, and for half the right-hand compartment was shielded. The response of normal animals to the two shield positions was significantly different from that of the gonadectomized animals, that is, on the average the normal animals moved in the direction of the shielded compartment while the gonadectomized rats indicated a slight trend in the opposite direction. Actually, all the observed shift among normal animals was attributable to the normal male group, with normal females indicating virtually no change.

A replication of the black-black shuttle-box experiment with 20 additional normal male rats yielded mean differences in the direction of the shielded compartment almost identical with those for norma males in the preceding experiment; however, large variance resulted in no statistically significant result in this later experiment.

A final experiment to be mentioned involved shuttle-boxes with one black and one medium-grey compartment. For half the rats the black side was shielded and for half the grey side was shielded A statistically significant shift in the direction of the shielded compartment was observed; and the magnitude of the observed shift was greater for male rats, although the sex differences were not statistically significant.

The results of these later experiments in which the only difference between the two treatments is a difference in the location of a protective lead shiel strongly suggest that a perceptual mechanism may take a minor but real role in the behavioural respons of albino rats to low-level radiation and that thi perceptual response is stronger in male rats. Thi latter conclusion is in contrast to the stronger "non-perceptual" response among female rats which wa noted in earlier experiments, and which was incidentally verified in the last mentioned experiment throug comparison with a non-radiation control group.

Radiation exposure produces changes in the amoun of time that an albino rat will spend in a normally preferred surrounding. Two mechanisms are suggested. The major determinant of the change is a generalized response to a radiation-induced physiological state. A perceptual-learning mechanism may take a minor role in the behavioural change observe in male rats.

The dose-rates employed in all experiments excep the one where additional dose-rates are specifically stated was 1 r. per min. in the air inside the shuttle-box compartments.

This work was conducted at the Radiobiologica Laboratory of the University of Texas and th United States Air Force, Austin, Texas, and wa supported (in part) with funds provided unde Contract *AF* 41(657)–149 and the School of Aviatio Medicine.

ENERGY-LINKED REDUCTION OF MITOCHONDRIAL PYRIDINE NUCLEOTIDE

By PROF. BRITTON CHANCE and DR. GUNNAR HOLLUNGER*

Johnson Research Foundation, University of Pennsylvania, Philadelphia

IN thermodynamic computations of reactions in biological systems[1] it has been customary to assume that the formation of reduced pyridine nucleotide proceeds in an exergonic reaction in which the free energy of the oxidation-reduction couple $(AH_2 \dashrightarrow A)$ is sufficiently negative with respect to reduced pyridine nucleotide itself that no extern energy source is required to drive the reaction[1]. Th article presents experimental results suggesting th the reduction of mitochondrial pyridine nucleoti can be accomplished by oxidation-reduction coupl having potentials several hundred millivolts high than that of the pyridine nucleotide couple[1–

*Permanent address: University of Lund, Sweden.

This discovery opens up new possibilities for utilization of substrates of high oxidation-reduction potential for pyridine nucleotide reduction with subsequent oxidation in various energy-yielding or synthetic reactions. It also indicates that the respiratory chain can utilize energy conserved at some sites to drive energy-requiring reactions at others.

The remarkable effect of succinate upon the reduction of intramitochondrial pyridine nucleotide was observed early in studies of rat liver mitochondria[4-6] and has recently been studied by Klingenberg *et al.*[18]. This reaction differs sharply from the fumarate oxidation of reduced pyridine nucleotide in non-phosphorylating Keilin and Hartree particles[7]:

$$\text{Fumarate} + \text{DPNH} + \text{H}^+ = \text{DPN}^+ + \text{succinate} \quad (1)$$

The reverse of this reaction requires an energy expenditure since the reductant couple ($A'\text{H}_2 \dashrightarrow A'$) affords insufficient free energy to reduce pyridine nucleotide:

$$\text{DPN}^+ + A'\text{H}_2 + X \sim I = \text{DPNH} + \text{H}^+ + A' + X + I \quad (2)$$

The driving force for such a reaction could be a high-energy intermediate of oxidative phosphorylation ($X \sim I$), which provides the energy required by the difference of oxidation-reduction potentials between the $A'\text{H}_2 \dashrightarrow A'$ couple and the pyridine nucleotide couple. In effect, $X \sim I$ raises the potential of pyridine nucleotide or lowers that of $A'\text{H}_2$ sufficiently to allow the reaction to proceed to completion[8]. This article illustrates the kinetics of reduction of pyridine nucleotide by succinate, particularly in kidney and heart mitochondria, where the extent of reduction of pyridine nucleotide by succinate greatly exceeds that of the usual diphosphopyridine nucleotide-linked substrates. The nature of the substance reduced is identified by spectroscopic and fluorometric data. In addition, the pathway of electron transfer is shown to involve carriers of the respiratory chain, the whole cytochrome chain for oxidation, and part of the chain for reduction. The great sensitivity of the reaction to energy expenditure (for example, by adenosine diphosphate) or to uncoupling of the phosphorylation clearly demonstrates the energy requirements for this reaction. In addition, a direct demonstration of a metabolic recovery process following energy expenditure in pyridine nucleotide reduction has been made.

Material and Methods

Rat liver[9] and guinea pig kidney mitochondria[10], and rat heart sarcosomes[11,12] were prepared by methods described elsewhere. The spectrophotometric[13,14] and polarographic[15] apparatus have been described previously.

Fluorometric measurement of the extent of reduction of mitochondrial pyridine nucleotide[16,17] is used to considerable advantage in rat heart preparations where this component is more difficult to observe than in rat liver preparations. It should be noted that Klingenberg *et al.*[18] (see particularly their Fig. 3*b*) have confirmed the difficulty of making measurements of reduced pyridine nucleotide in rat heart preparations due to the change in absorbancy at 320 mμ[12]; the fluorometric method has much to recommend it for assays of reduced pyridine nucleotide where partial depletion of mitochondrial pyridine nucleotide has occurred and where the chemical method may fail to demonstrate its presence[18].

Succinate-linked Reduction of Pyridine Nucleotide

The data of Figs. 1 *A* and *B* provide examples of spectrophotometric and fluorometric recordings of pyridine nucleotide reduction in kidney and heart mitochondria. The recordings of Fig. 1*A* were obtained with the double-beam spectrophotometer set at measuring wave-lengths appropriate for the reduction of pyridine nucleotide (340 or 350 mμ) and at a nearby reference wave-length (374 mμ). The same phenomenon can be recorded fluorometrically with 366 mμ excitation and 443 mμ measurement[17]. Treatment of the mitochondria in state 1 with adenosine diphosphate gives state 2, a more highly oxidized state of pyridine nucleotide. Addition of 4 m*M* glutamate causes pyridine nucleotide reduction (downward deflexion of the traces) and initiates respiration until the added adenosine diphosphate is exhausted, when a further reduction of pyridine nucleotide is observed (state 4_g). The process may be repeated with a second addition of adenosine diphosphate, as in Fig. 1*B*. In both cases addition of 4 m*M* succinate causes a large, rapid downward deflexion of the trace which these studies indicate to be due to an increased reduction of pyridine nucleotide (state 4_s). Addition of adenosine diphosphate to the mitochondria treated with glutamate and succinate causes an oxidation of the reduced pyridine nucleotide (state 3_s). These experiments demonstrate that the extent of reduction of pyridine nucleotide by succinate considerably exceeds that obtainable with glutamate alone. Mitochondria isolated from ascites tumour cells also show this effect[19]. Bücher and Klingenberg have demonstrated the reduction of pyridine nucleotide in locust sarcosomes by α-glycerophosphate[20,21]. More recently, Klingenberg *et al.*[18] have confirmed our studies on heart and kidney mitochondria. Other pyridine nucleotide-linked substrates of the citric acid cycle have no greater effect than glutamate, and the succinate effect is

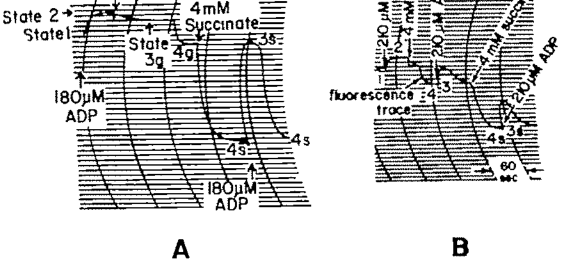

Fig. 1. Comparison of the effects of glutamate and succinate on pyridine nucleotide reduction in guinea pig kidney (*A*) and rat heart mitochondria (*B*). The time-scale increases from left to right; the reagents and states of the mitochondria are indicated in the figures. *A*, spectrophotometric recording at 350–374 mμ; *B*, fluorometric recording, 366 mμ excitation, 443 mμ measurement. Mitochondria suspended in isotonic medium, 26°. (Expts. 658a–10, 791–1)

sensitive to malonate (50 per cent inhibition for malonate/succinate = 0·35).

The pathway of the succinate-linked pyridine nucleotide reduction is not the main pathway of electron transfer; the maximal rate of reduction is about equal to the state-4 rate of oxygen utilization or roughly one-fifth the state-3 rate. Nevertheless, this pathway appears to have considerable theoretical interest and may be of physiological importance.

It is important to clarify the results obtained previously with rat liver mitochondria[22]. In this material, succinate causes reduction of pyridine nucleotide, but its effect is not appreciably in excess of that caused by β-hydroxybutyrate. In more recent comparisons of the effects of glutamate and succinate on rat liver mitochondria, similar to those of Fig. 1, the ratio of the increment on adding succinate (4_s–4_g) to the effect of glutamate alone (4_g–2) is only 0·22. The corresponding average values for heart and kidney mitochondria are 2·1 and 3·3 respectively. The discovery of a large amount of triphosphopyridine nucleotide in mitochondria[20,23] affords an explanation for this difference: apparently triphosphopyridine nucleotide is affected similarly by succinate and β-hydroxybutyrate and thereby obscures accurate spectrophotometric detection of differences in the effect of these two substrates upon the diphosphopyridine nucleotide of liver. For this reason, kidney and heart mitochondria are more suitable for spectrophotometric and fluorometric studies than are liver mitochondria. In previous studies we noted a much smaller pyridine nucleotide–cytochrome *a* ratio in rat heart than in rat liver mitochondria when using α-oxoglutarate as substrate[12]. The larger pyridine nucleotide reduction obtainable with succinate now gives a ratio of ~ 9 : 1, which is about half that for liver mitochondria[24].

Nature of Reduction Product

Spectrophotometric and fluorometric data. To identify the material reduced by succinate and oxidized by adenosine diphosphate, as indicated in Fig. 1, we have recorded spectra representing absorbancy differences between state 4_s and state 3_s in succinate-reduced mitochondria. Fig. 2 also represents studies of two preparations, one from guinea pig kidney (*A*) and one from rat heart (*B*). The increased absorbancy on adding succinate to substrate-free mitochondria (state 2) to give 340 mμ absorption (state 4) is indicated in Fig. 2*A*. Fig. 2*B* shows that the addition of adenosine diphosphate to succinate-treated mitochondria (state 4) causes a band with a maximum at 340 mμ to disappear (note the negative values of the ordinate). The peaks of the spectra are close to 340 mμ, as would be expected for the oxidation and reduction of pyridine nucleotide. Other studies show the succinate-reduced material to have a fluorescence maximum at 443 mμ[16].

It appears that the succinate-reduced material has the physical properties characteristic of the reduced state of pyridine nucleotide. Since, as indicated below, the material so reduced can be oxidized in an amytal-sensitive reaction by the respiratory chain, it is concluded that a reduced form of pyridine nucleotide is formed in this reaction. It is further concluded that the reduced form is bound to some ligand, for example, a protein, because the fluorescence maximum is at 443 mμ[25,26]. Thus this material is denoted DPNH ~ *I*[27] although Slater currently uses the description DPN ~ *I*H (cf. refs. 29, 35). Actually, the two forms could resonate. There are no data available to indicate the chemical nature of ~ *I*. We found that DPNH ~ *I* was refractory to acetoacetate[30,31] or to ferricyanide[32] oxidation, and Purvis believes that it is refractory to low concentrations of alcohol dehydrogenase[33] (but compare below and ref. 34). The interesting possibility that ubiquinone–coenzyme *Q* may be the ligand[35] remains an unsupported hypothesis and now appears to be inconsistent with the reduced pyridine nucleotide and ubiquinone contents of guinea pig kidney mitochondria, which are in the ratio of about 4 : 1 (ref. 36).

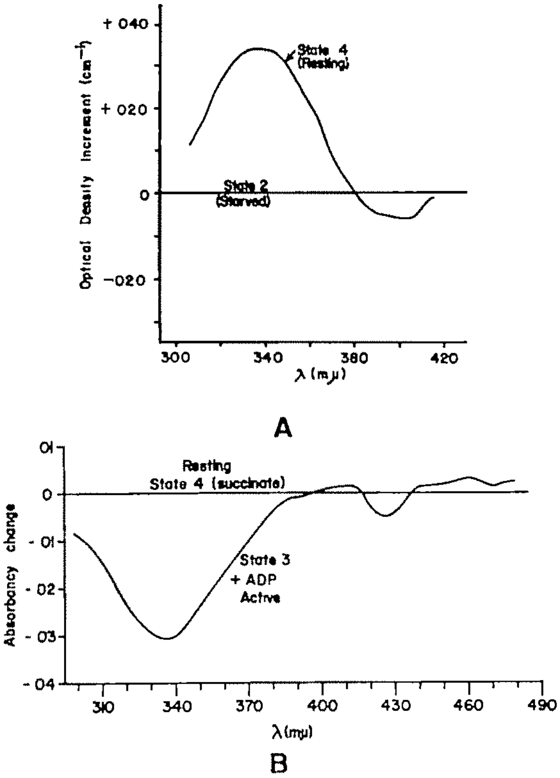

Fig. 2. Spectroscopic changes caused by succinate addition to 'starved' guinea pig kidney mitochondria (*A*) and adenosine diphosphate addition to succinate-treated rat heart mitochondria (*B*). Conditions similar to Fig. 1. (Expts. 664*b*–1, 771*c*–3)

Chemical data. Chemical determinations of the material reduced by succinate, particularly in the kidney mitochondria, are in agreement with the conclusion above[18,37] (also Bücher and Klingenberg, personal communication). The increased absorbancy obtained on adding succinate to the kidney mitochondria is very nearly equal to the decrease of absorbancy caused by adding alcohol dehydrogenase and acetaldehyde to a neutralized sodium carbonate extract of such mitochondria. Thus, it can be said that nearly the same amount of material reduced by succinate in the guinea pig kidney mitochondria can be re-oxidized by dilute yeast alcohol dehydrogenase and acetaldehyde in an extract. This result differs from that obtained by Purvis[38] and Slater[26], who used rat liver mitochondria. It also indicates that diphosphopyridine nucleotide is involved, in agreement with Bücher and Klingenberg[18] (and personal communication). Thus, succinate acts as a powerful reductant of mitochondrial diphosphopyridine nucleotide.

Pathway of Reduction and Oxidation

It is now appropriate to consider the pathway for reduction and oxidation of mitochondrial pyridine nucleotide by succinate. The fact that the oxidation-reduction of succinate-reduced diphosphopyridine nucleotide closely follows the increases and decreases of respiratory activity accompanying the state 4–3–4 transitions suggests that this component is closely associated with the respiratory chain. The oxidation of reduced diphosphopyridine nucleotide has been found to be sensitive to cyanide, antimycin-*A*, and amytal. It can therefore be concluded that pyridine nucleotide reduced by succinate is oxidized by the same pathway as the pyridine nucleotide reduced by the usual diphosphopyridine nucleotide-linked substrates.

Pyridine nucleotide reduction could be activated by a decrease in the velocity of its oxidation or by an increase in the velocity of its reduction, either along the usual pathway or by the activation of a new pathway. We have carefully examined the possibility that the addition of succinate decreases the flow of oxidizing equivalents to reduced pyridine nucleotide by reducing the steady-state oxidation-level of cytochrome *b*. In this case, addition of excess cyanide should cause pyridine nucleotide reduction at a rate exceeding that caused by addition of succinate. This has not been observed in freshly prepared mitochondria with either cyanide or hydrosulphide as inhibitor. In mitochondria depleted of endogenous substrate, addition of cyanide after glutamate causes a slow and incomplete reduction of pyridine nucleotide, whereas addition of succinate causes a complete and three times as rapid reduction. These experiments appear to eliminate a decrease of reduced pyridine nucleotide oxidase activity as a complete explanation. Thus we have considered the succinate effect to be an activation of pyridine nucleotide reduction. Since the increased rate of pyridine nucleotide reduction by succinate is slowed by amytal (see below), we can eliminate an increase of glutamic dehydrogenase activity. The succinate-linked effect probably results from an activation of pyridine nucleotide reduction through an amytal-sensitive flavoprotein interaction, essentially a reversal of electron transfer between cytochrome *b* and reduced pyridine nucleotide via flavoprotein (cf. ref. 18). The reducing equivalents may flow from succinate directly or from glutamate via a small amount of directly reduced pyridine nucleotide[39] to the larger pool of pyridine nucleotide. The above-mentioned results with cyanide and the unpublished results of Klingenberg and Bucher (cf. ref. 18) on α-glycerophosphate support the former view which is embodied in the equations which follow. Ubiquinone–coenzyme *Q* is not yet included in these equations, but experiments on non-phosphorylating preparations would place it next to flavoprotein[40], in which case the conclusions reached here would be unchanged since direct transfer through ubiquinone, as through flavoprotein, would be insensitive to antimycin *A*.

The pathway for the reduction of the material is also indicated by its inhibitor sensitivity. The malonate and amytal sensitivity of the pathway of reduction of pyridine nucleotide which is demonstrated by spectroscopic experiments suggests a transfer pathway similar to that of equation 3, where interaction between flavoproteins (fp_1 and fp_3) causes the reduction of pyridine nucleotide:

$$\begin{tikzcd}
 & & & c_1 & & & \\
 & & & {} & \text{antimycin-}A \arrow[l] & & \\
 & & & b \arrow[uu] & & & \\
 & \text{malonate} \arrow[d] & & & & \text{amytal} \arrow[d] & \\
\text{succinate} \arrow[rr] & {} & fp_1 \arrow[rr] \arrow[uur] & & fp_3 \arrow[uul] & {} & \text{DPN} \arrow[ll, leftrightarrow]
\end{tikzcd} \qquad (3)$$

Such a pathway is in accord with the suggestions of Beinert[41], who favours the idea of direct transfer between flavoproteins. The reduction of diphosphopyridine nucleotide by a diaphorase preparation has recently been studied by Massey[42] and by Searls and Sanadi[43]. However, the tenfold increase in the speed of reduction of cytochrome *b* in the amytal-treated material, together with the fact that the reduction of pyridine nucleotide is slower in the presence of antimycin-*A* than in the presence of cyanide, suggests that reducing equivalents for diphosphopyridine nucleotide pass through the respiratory chain at the level of cytochrome *b*:

$$\begin{tikzcd}
 & & & c_1 & & & & \\
 & & & {} & \text{antimycin-}A \arrow[l] \arrow[d] & & & \\
\text{succinate} \arrow[rr] & {} & fp_1 \arrow[r] & b \arrow[uu] \arrow[rr] & {} & fp_3 & {} & \text{DPN} \arrow[ll, leftrightarrow] \\
 & \text{malonate} \arrow[u] & & & & & \text{amytal} \arrow[u] &
\end{tikzcd} \qquad (4)$$

Since the site of action of antimycin-*A* is between cytochromes *b* and c_1, it is suggested that an inhibition of the ability of cytochrome *b* to transfer reducing equivalents along the chain has occurred. In the case of pyridine nucleotide reduction, antimycin-*A* would be inhibiting the ability of cytochrome *b* to transfer reducing equivalents to the flavoprotein, fp_3, involved in this reduction reaction (see equation 4). The pathways indicated by this equation are in satisfactory accord with the kinetic data on the effect of the indicated inhibitors upon the kinetics of cytochrome *b*, flavoprotein, and pyridine nucleotide, and represent a working hypothesis for discussions of this reaction.

These pathways of equation 4 are written in the usual abbreviated symbolism for the respiratory chain in equation 5:

$$\begin{tikzcd}
 & & \text{succinate} \arrow[r] & fp_1 \arrow[dr] & & & & & & \\
\text{glutamate} \arrow[r] & \text{DH} \arrow[r] & \text{DPNH} \arrow[r] & fp_2 \arrow[r] & b \arrow[r] & c_1 \arrow[r] & c \arrow[r] & a \arrow[r] & a_3 \arrow[r] & O_2 \\
 & & \text{DPNH} \arrow[r, leftrightarrow] & fp_3 \arrow[ur, leftrightarrow] & & & & & &
\end{tikzcd} \qquad (5)$$

This scheme indicates that the pathway for the oxidation of succinate-reduced diphosphopyridine nucleotide proceeds by the same pathway as the reduction. However, this reduced diphosphopyridine nucleotide could equally well diffuse to another set of respiratory carriers and be oxidized there.

Comparison of Succinate and Glutamate Reduction

The chief result of the experiments so far is to show that a larger reduction of diphosphopyridine nucleotide occurs by a succinate-linked pathway through the respiratory carriers than can be achieved by diphosphopyridine nucleotide-linked dehydrogenases. A simple kinetic explanation based upon a greater speed of reduction by succinate appears to be inadequate: the glutamate reduction of diphosphopyridine nucleotide in state 3, as indicated by the respiratory activity, exceeds the rate at which succinate can activate pyridine nucleotide reduction, as illustrated in Fig. 1; fp_2 is rapidly reduced but cannot transfer its electrons rapidly to fp_3 and pyridine nucleotide without the mediation of succinate. Thus an adequate kinetic explanation depends upon a greater rate of electron transfer through fp_2 in the presence of succinate than in the presence of glutamate alone. Also, explanation for the partial reduction of the pyridine nucleotide linked to fp_2 by glutamic dehydrogenase activity is required.

An explanation suggesting that diphosphopyridine nucleotide is reduced by the diphosphopyridine nucleotide-linked dehydrogenases of the mitochondria and triphosphopyridine nucleotide by the succinate-linked pathway has no foundation in the chemical analyses of the kidney mitochondria, which show the presence of very little triphosphopyridine nucleotide[18].

A hypothesis based on chemical difference between the glutamate- and succinate-reduced diphosphopyridine nucleotide in mitochondria which are linked to their reductase system is indicated in the equations below:

$$\text{Glutamate} \dashrightarrow \text{DH} \dashrightarrow \text{DPNH} \sim I \quad (6)$$

$$\text{Succinate} \dashrightarrow (\text{Carriers}) \dashrightarrow fp_3 \dashrightarrow \text{DPNH} \sim I' \quad (7)$$

We here distinguish between the kinds of pyridine nucleotide by the nature of the ligand which inhibits electron transfer in state 4, that appropriate to the glutamic dehydrogenase pyridine nucleotide being designated I and that appropriate to the succinate-linked component being designated as I'. Thus, glutamate has direct access to DPNI and can reduce it directly. Succinate, acting through the respiratory carriers, activates DPNI' through its specific flavoprotein (fp_3). This mechanism explains the way in which succinate and glutamate can reduce different amounts of pyridine nucleotide on the basis of chemical specificity. There are two observations that require an elaboration of this hypothesis. In anaerobiosis, the full amount of diphosphopyridine nucleotide is slowly reduced in the absence of added succinate. Also succinate reduces the total diphosphopyridine nucleotide of the kidney mitochondria in the absence of added glutamate. Both these effects could be explained by diphosphopyridine nucleotide-reduced diphosphopyridine nucleotide transhydrogenase activity[44], which is insufficient to be active aerobically but which nevertheless acts on the two forms of diphosphopyridine nucleotide of equation 6, above, in anaerobiosis.

A slow glutamate-linked transhydrogenase activity would afford a better basis for a kinetic explanation of the different degrees of diphosphopyridine nucleotide reduction by glutamate and succinate. Such an activity could well utilize the pathways of equation 5, fp_1 being more effective than fp_2 in the reduction of pyridine nucleotide via fp_3.

An alternative hypothesis is that diphosphopyridine nucleotide is specifically bound to glutamate- and succinate-linked reducing sites. Such a condition would immediately satisfy the larger reduction of pyridine nucleotide by succinate and a smaller reduction by the usual glutamate-linked and other substrates. Evidence for the binding of mitochondrial pyridine nucleotide has already been presented above from fluorometric experiments. This apparently simple hypothesis becomes more complicated when it is considered that all diphosphopyridine nucleotide-linked substrates apparently reduce the same amount of pyridine nucleotide (α-oxoglutarate, glutamate, malate, β-hydroxybutyrate). Thus, the pyridine nucleotide bound at the glutamate site must be readily available to the other diphosphopyridine nucleotide-linked dehydrogenases (but not to the succinate-linked pathway). Preliminary evidence that adenosine diphosphate (and uncoupling agents) may inhibit the binding of pyridine nucleotide to its succinate-linked site is afforded by fluorometric data which show diminished fluorescence of pyridine nucleotide in anaerobiosis where adenosine diphosphate can accumulate.

There is apparently no difficulty in providing adequate binding sites for pyridine nucleotide at the succinate-linked site, since it is not unusual to have four molecules of pyridine nucleotide bound to a single protein[45].

Compartmentation of an identical chemical species of pyridine nucleotide would also explain the experimental data; it is conceivable that the glutamate-linked material is bound to the cristæ and the succinate-linked material to the matrices. It is necessary to assume that such compartments are slowly equilibrated in anaerobiosis, and that the matrix material can reach fp_3 but not glutamic dehydrogenase in aerobiosis.

Of these hypotheses only the simple kinetic explanation appears inconsistent with available experimental data. Those hypotheses involving: (1) a slow glutamate-linked transhydrogenase activity; (2) chemical specificity; (3) bound pyridine nucleotide; and (4) structural compartmentation must remain under active consideration.

Energy Expenditure in Reduction of Diphosphopyridine Nucleotide

The data above suggest that pyridine nucleotide reduction is associated with not only the reducing power of succinate but also the electron transfer from succinate to oxygen. In fact, the maximal rate of succinate-linked pyridine nucleotide reduction is about equal to the rate of electron transfer in state 4. This correlation, combined with the high sensitivity of the reaction to uncoupling agents, has led us to investigate whether there is a demonstrable energy requirement for this reaction. First, we shall consider the thermodynamic properties of such an energy-linked reaction.

Thermodynamic potential. In considering the energy requirements for the succinate-linked reaction, it is highly desirable to indicate the thermodynamic potential against which this reaction can occur. The graph of Fig. 3 indicates a titration of diphosphopyridine nucleotide of kidney mitochondria with succinate in the absence of fumarate and in the presence of 30 mM fumarate. In the absence of added fumarate, 190 μM succinate gives half-maximal reduction. To obtain an estimate of the potential

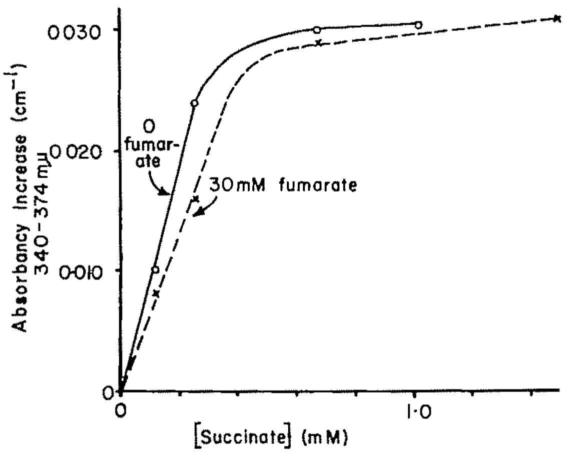

Fig. 3. A titration of pyridine nucleotide of guinea pig kidney mitochondria with succinate in the absence and in the presence of 30 m*M* fumarate. Mitochondria pretreated with 4 m*M* glutamate and then titrated with succinate (cf. Fig. 1). (Expt. 715*d*)

against which this reaction will occur, the titration is repeated in the presence of 30 m*M* fumarate; in this case, 215 μ*M* succinate gives half-maximal reduction. This increase in succinate concentration is so small that the question may be raised as to whether the system is in equilibrium (the fumarate/succinate ratio differs by roughly 10^4 in the two titrations (see also refs. 29, 46)). If we assume an equilibrium, the redox span ranges from 34 mV. (ref. 2) to − 320 mV. (ref. 3) or a total of 354 mV. Even if the assumed equilibrium is proved incorrect, it is clear that the reaction has a considerable energy requirement.

Effect of uncoupling agents. If the overall process involves a high-energy intermediate,

$$\text{Succinate} + \text{DPN}^+ + X \sim I \dashrightarrow \text{fumarate} + \text{DPNH} + X + I + \text{H}^+ \quad (8)$$

uncoupling agents should inhibit the reaction. Table 1 summarizes the concentration of uncoupling agents giving half-maximal effects. It is seen that extremely low concentrations are effective in inhibiting this reaction. More detailed studies identify an inhibition of the reduction as opposed to an activation of the oxidation because of the effects of the uncoupling agent.

It can be seen that the concentration of mitochondrial reduced pyridine nucleotide can be regulated over wide ranges by balancing the reductive effect of succinate against the oxidizing effect of adenosine diphosphate or of substances such as thyroxine which act at such low concentrations that the phosphorylation efficiency would be largely unaffected.

Table 1. CONCENTRATIONS OF UNCOUPLING AGENTS* GIVING 50 PER CENT INHIBITION OF THE RATE OF DPN REDUCTION BY 4 m*M* SUCCINATE (K_m). GUINEA PIG KIDNEY MITOCHONDRIA, SUCROSE-SALT MEDIUM, 26°

* DBP, Dibromophenol; DNP, Dinitrophenol; DIC, Dicoumarol; DIB, Butyl-3,5-diiodo-4-hydroxybenzoate.

Effect of adenosine triphosphate. In view of the postulated requirement of the succinate-linked reduction for a high-energy intermediate, it appeared reasonable that the addition of adenosine triphosphate would accelerate the reduction reaction. Mitochondria in which the extent of reduction was inhibited ~ 50 per cent by 24 μ*M* dibromophenol were treated with a high concentration of adenosine triphosphate (0·8 m*M*), but no measurable increase of reduction was observed. Apparently the added adenosine triphosphate caused no increase in the concentration of intermediates suitable for reducing the pyridine nucleotide.

Effect of phosphate. In an effort to determine whether the reduction reaction is driven by an $X \sim I$ or an $X \sim P$ compound, the succinate-linked reduction was demonstrated in a phosphate-free medium and found to proceed unchanged in rate or extent. Control experiments based on the lack of a spectroscopic response to the addition of adenosine diphosphate suggested that less than one-twelfth the required amount of $X \sim P$ (see calculations below) could have been present under the experimental conditions.

Recovery from energy expenditure. Equation 8 suggests that the breakdown of $X \sim I$ would result in an activation of oxidative recovery to restore the energy expended in reduction of diphosphopyridine nucleotide. If mitochondria are treated with a low concentration of azide (50 μ*M*), changes in the steady state oxidation-reduction level of the cytochromes due to activation of electron transfer in oxidative recovery are sensitively indicated[47] (Fig. 4). Mitochondria pretreated with glutamate and azide are in state 4. Addition of succinate causes a downward deflexion of the fluorometric trace which corresponds to increasing reduction of pyridine nucleotide. Simultaneously, the trace corresponding to cytochrome *a* shows a cycle of reduction and oxidation which suggests that oxidative recovery is initiated upon adding succinate.

The experiment of Fig. 4 can be made quantitative if a known amount of adenosine diphosphate is added to compare its effect with that of the succinate. Thus, 110 μ*M* adenosine diphosphate is added, giving a larger and longer cycle of reduction of cytochrome *a* than did succinate. (The fluorescence trace shows that, in this instance, reduced pyridine nucleotide

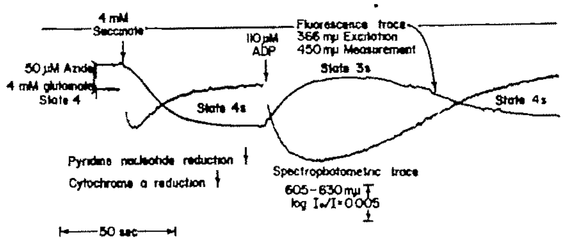

Fig. 4. A demonstration of recovery from energy expended in the reduction of pyridine nucleotide by succinate. Rat liver mitochondria pretreated with 4 m*M* glutamate and 50 μ*M* azide. Energy recovery is indicated by the cycle of reduction and oxidation of cytochrome *a* (measured at 605–630 mμ) caused by the succinate-linked reduction of pyridine nucleotide. 110 μ*M* adenosine diphosphate is added to calibrate the energy recovery (10°). (Expt. 9706–13)

is oxidized, as is the usual case in the state 4-to-3 transition.) A comparison of the areas under the curves corresponding to addition of adenosine diphosphate and succinate reveals that 8 per cent of the area corresponding to 110 μM adenosine diphosphate is caused by succinate addition. In other words, a resynthesis of a high-energy intermediate corresponding to the utilization of 9 μM adenosine diphosphate (22·5 mμmoles) is required. If the amount of mitochondria is varied, a straight-line relationship between the amount of mitochondrial protein and the amount of respiratory resynthesis is found, suggesting that a stoichiometric relationship exists between energy expenditure and pyridine nucleotide reduction. Finally, computing, by suitable calibrations based upon absorbancy changes at 340 mμ, the number of adenosine diphosphate equivalents required to form 1 mole of reduced diphosphopyridine nucleotide, a ratio of $\sim$ 3 : 1 is obtained. It is further found that pretreatment of the mitochondria with amytal does not reduce the energy expenditure upon succinate addition to zero; 30 per cent remains. Thus, for the specific reduction of diphosphopyridine nucleotide by succinate, 2 adenosine diphosphate equivalents are required. We may make preliminary assignments of the energy expenditure at the sites indicated by the following equation:

$$\text{Succinate} \dashrightarrow fp_1 \dashrightarrow b \underset{\overset{\uparrow}{X \sim I}}{\dashrightarrow} fp_3 \underset{\overset{\uparrow}{X \sim I}}{\dashrightarrow} \text{DPNH} \underset{\overset{\uparrow}{X \sim I}}{\dashrightarrow} \text{DPNH} \sim I \qquad (9)$$

This suggests that the succinate-linked reaction not only reduces pyridine nucleotide to the level of − 320 mV. but, further, forms a high-energy bond between it and its ligand, I. However, the technique used in the assay of the adenosine diphosphate equivalents formed is a novel one and some confirmation by independent means would appear to be desirable.

It is not surprising that the energy expenditure in this reduction is high relative to the one adenosine triphosphate equivalent obtained in the oxidation of reduced diphosphopyridine nucleotide because the reduction reaction must pay the full cost of the reaction. For the span between fp_3 and DPNH $\sim I$, the energy conserved as adenosine triphosphate in the oxidation reaction appears to be about one-half of the energy cost of reduction. In this sense, this experiment gives us a rough estimate of the efficiency of oxidative phosphorylation in this part of the chain.

'*Energy transferase*'. It is apparent that high-energy intermediates formed in the cytochrome portion of the chain by succinate oxidation can be used to reduce diphosphopyridine nucleotide. It is also true that glutamate treatment of the mitochondria increases the speed of the succinate-linked reduction, suggesting that the high-energy intermediate formed from diphosphopyridine nucleotide can also participate in diphosphopyridine nucleotide reduction. This is a sort of transhydrogenase activity. In addition, such reduced diphosphopyridine nucleotide can, by its oxidation, form other high-energy intermediates. Thus, there can be an equilibration of high-energy intermediates in the respiratory chain, essentially an 'energy transferase' activity as suggested some time ago by Lipmann[48]. The existence of such a reaction further suggests that intermediates of various energy contents may be used to increase the ratio of reduced to oxidized diphosphopyridine nucleotide until the potential of the system is sufficient to form an intermediate capable of phosphorylating adenosine triphosphate. Such a possibility greatly widens the range of sites that can be considered for energy conservation and may ultimately make the assignment of a particular phosphate bond to a particular redox couple unrealistic. Thus, even more attention may be focused upon the experimentally observed loci, namely, the three sites at which inhibitory interactions are identified by the crossover theorem[49].

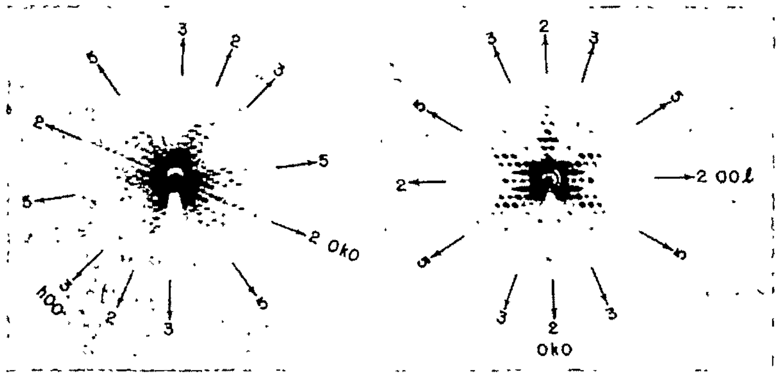
VIROLOGY

Sub-Units in Southern Bean Mosaic Virus

Two results have emerged from preliminary X-ray diffraction studies of single crystals of southern bean mosaic virus. The first, and the more important one, is information about the structure of the virus particle proper, and the second about the packing of the particles in the crystal. Each particle is composed of identical sub-units, and the particles are arranged in hexagonal close-packing to form the crystal. The fact that this virus, like other small 'spherical' ones previously studied, is composed of sub-units again confirms the hypothesis made by Crick and Watson[1]. They suggested that the protein sub-units pack in cubic point-group symmetry and that there are either 12, 24 or 60 such units depending on whether the symmetry of the particle is tetrahedral, octahedral or icosahedral.

Southern bean mosaic virus crystallizes in the orthorhombic system with a probable space group of $C222_1$. There are four particles in the unit cell of dimensions $a = 295$ Å., $b = 508$ Å. and $c = 474$ Å. Because the ratios of cell dimensions are $b/a = \sqrt{3}$ and $c/a = 1{\cdot}61$, and all interparticle distances are probably equal, the virus particles must be hexagonally close-packed in the crystal. Thus, the centre-to-centre distances of the particles in the crystal are 295 Å. This diameter of virus is essentially the same as the value of 286 Å. obtained from small-angle scatterings of X-rays by southern bean mosaic virus particles in suspension[2].

Diffraction patterns of the wet crystals grown in distilled water show reflexions down to spacings of 5 Å., indicating relatively high crystal perfection, with one virus particle very similar if not identical to another. Two of the patterns, $hk0$ and $0kl$, are shown in Figs. 1*a* and *b*. The conspicuous features of these patterns are the regions of high intensity which correspond to the transform of the individual particle. Although the lattice imposes 222 symmetry on the particle, the positions of the high-intensity streaks (rotation axes marked in Fig. 1) are those of the 532 axes of the cubic icosahedral point group. The three perpendicular two-fold axes are parallel to the *a*-, *b*- and *c*-axes of the orthorhombic lattice.



(*a*) (*b*)

Fig. 1. 2° precession photographs of southern bean mosaic virus crystals taken with the X-ray beam parallel to (*a*) the *c*-axis and (*b*) the *a*-axis. The orientations of the five-, three- and two-fold rotation axes of the icosahedral point group 532 are indicated and coincide with the directions of the strongest intensities

If the virus has true icosahedral symmetry, it must be composed of sixty identical or nearly identical protein sub-units. Should the sub-units differ by one or two amino-acids, this would not be detectable in the X-ray patterns. Each sub-unit would have a molecular weight of 85,000, as calculated from the 21 per cent nucleic acid[3] and the molecular weight of the virus of $6{\cdot}63 \times 10^6$ (ref. 4). However, these units may be sub-divided. From amino-acid analysis it is known that the protein chain has a minimum molecular weight of 27,000 (ref. 5). Thus, there are probably three similar protein chains in each of the sixty equivalent units of molecular weight 85,000. The ribonucleic acid, by analogy with the other viruses and from preliminary small-angle scattering of X-rays, is probably located within the protein framework. Little is known about it from the X-ray observations at this stage of investigation, except that if it is not a randomly oriented chain it must have at least four sub-units subject to 222 symmetry. That there may be four sub-units merely means that these units are similar structurally but not chemically.

Southern bean mosaic virus resembles tomato bushy stunt[6], turnip yellow mosaic[7], and polio[8] in that all these particles are probably composed of sixty identical or near-identical protein sub-units which pack in icosahedral symmetry to form the framework of the virus. However, at present, neither the shape of the protein sub-units nor that of the virus itself is known about any of the particles examined. By comparing the data for all these particles, it can be seen that southern bean mosaic virus differs from the other three. The diffraction patterns have a different aspect since the streaks of high intensity are much broader for southern bean mosaic virus. It is not unlikely that the shape of the sub-unit affects the sharpness of the streaks.

Another dissimilarity is in the number of interparticle contact points in the lattice. The other plant viruses crystallize in the cubic system, giving body-centred packing with the contact points of the particles along the three-fold axis of both the cell and the particle. Polio virus, although it crystallizes in the orthorhombic class, packs in a lattice which is scarcely distinguishable from body-centred cubic. In the case of southern bean mosaic virus, due to the hexagonal close packing there are four different contact points: two in the hexagonal plane, one of which is along one of the twofold axes of the cell, and the other along the cell diagonal, close to a five-fold axis of the particle. The contact points of one particle to its three neighbours in the next layer are of two kinds and differ from those in the plane.

More detailed results will be published in the *Contributions from Boyce Thompson Institute*.

PHYSICS

Pumping Effect of a Gas Discharge High-Vacuum Pump

SIX years ago Foster *et al.*, of the California Radiation Laboratory, constructed a high-vacuum pump with high pumping speed (3,000–7,000 litres/sec.) based on the principle of transport of ions during a discharge in a magnetic field[1]. The limiting pressure reached was less than 1×10^{-8} mm. mercury and the residual gases were free of hydrocarbon vapour. This pump at first caused much interest, but was soon forgotten in favour of more economic pumps based on the pumping effect of evaporated titanium[2].

In our laboratory we have studied some properties of this pump[3]. In the first place, it was necessary to construct a gas discharge pump for experimental work on a small scale, so that it would be relatively easy to make constructional alterations. The discharge tube was made of hard glass (diameter 42 mm., length 1,200 mm.); the inlet opening was at the centre of the tube, the two outlet openings being at the respective ends and connected to a rotary pump by a two-way stop-cock. At both ends an electrode system was point-welded to molybdenum seals. Each electrode system consists of a cathode (a heated tungsten filament and molybdenum target) and a molybdenum ring anode fixed to two long molybdenum tie-beams enclosed in glass. In direct proximity to the anodes in the direction towards the centre, the tube was narrowed for a length of about 5 cm. to a diameter only a little larger than the diameters of the holes in the anodes (28 mm.). The solenoid of the vacuum-pump, which was run by a d.c. power supply (consumption 4 kW.), was placed on the outside of the tube. Parts of the solenoid which were in the neighbourhood of the outlets had more turns of wire than the others; in this way it was possible to obtain a sufficient intensity of the magnetic field throughout the region of the outlet openings, which was necessary for focusing the discharge without the necessity for using an internal solenoid (as in the apparatus of ref. 1). The combination of ring anodes and narrowing of the tube makes it unnecessary to have the anodes very close to the discharge tube.

The second problem was to find the dependence of the pumping speed on pressure by varying the inlet opening (that is, for different diameters of the inlet opening, for different distances between the solenoids and therefore for different intensities of the magnetic field in the region of the inlet opening). The pumping speed was deduced from the pressure drop, which was measured by a cold-cathode ionization gauge and by a McLeod gauge, both of which were connected to the evacuated region. The maximum pumping speed with an inlet opening containing three tubes of total cross-section 1·9 cm.^{2} was 18 litres/sec. (ref. 3). In this case the distance between the solenoids was 12 mm. The maximum pumping speed for one tube of 3·2 cm.^{2} cross-section was 34 litres/sec.; in this case the distance was 32 mm. The mean intensity of the magnetic field was 1,250 Oe., anode voltage 280 V. The dependence of pumping speed on pressure is shown in Fig. 1*a*. The pumping speed reaches a maximum for pressures of the order of 10^{-5} mm. mercury and decreases to the limiting pressure of 8×10^{-7} mm. mercury of this system.

According to present views, there are two processes involved in this pump: the transport of ions from the region of the inlet opening through the anodes into the regions of the cathodes, and sorption processes. Foster *et al.*[1] attributed the pumping effect to the transport of ions. This explanation was criticized and the effect was attributed to sorption processes, since pumping continued even after the fore-vacuum pump was disconnected. In order to show how the two effects participate in the total pumping effect the following experiments were carried out.

It was found that pumping continues (in agreement with Foster *et al.*[1]) even after the disconnexion of the rotary pump. During the measurement of the pressure drop in the evacuated system, which was carried out from the moment of closing the stop-cock connecting the discharge pump with the rotary pump, the pressure drop in the outlet openings was also measured by a gauge. This gauge showed a drop in pressure, which was, however, much smaller than

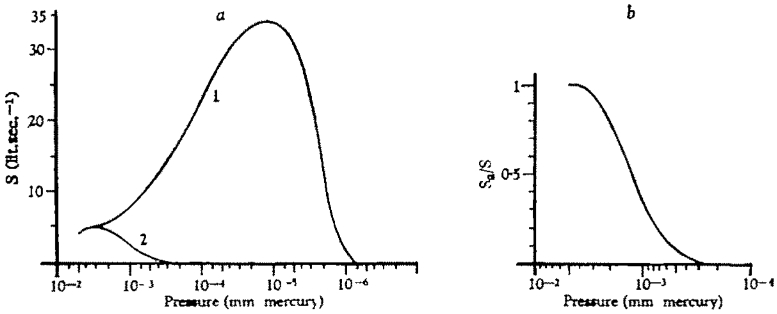

Fig. 1. Course of the pumping speed and the fraction of the total pumping effect allotted to the sorption mechanism in dependence on pressure. (*a*) Curve 1, pumping speed in the evacuated region; curve 2, pumping speed in the fore-vacuum region. (*b*) Dependence of the fraction of the total pumping effect caused by the sorption mechanism on pressure

the corresponding drop in the evacuated region. By comparing the pumping speeds in the evacuated and fore-vacuum region (Fig. 1*a*) it is found that the pumping speed S_a in the fore-vacuum region (which cannot be attributed to the transport process) as a fraction of the total pumping speed S is strongly dependent on pressure (Fig. 1*b*), and for pressures less than $2 \cdot 4 \times 10^{-4}$ mm. mercury the pump evacuates on the principle of transport and recombination of ions. It is plausible that the transport of ions becomes of importance at pressures where the mean free path becomes greater than the linear dimensions of the tube. (The values of pumping speed in the fore-vacuum region were also evaluated from the drop in pressure, that is, assuming constant volume of gas; this supposition is not quite correct, because molecules constantly flow from the high-vacuum region into the fore-vacuum region; that is why the cited values of pumping speed are only approximate.)

Finally, an experiment was carried out in which one of the anodes was inclined from its position. Hence the focused discharge was also inclined, so that a gap arose between the discharge column and the wall of the tube in the narrowed region of the tube connecting the fore-vacuum with the high-vacuum region. In the space of this gap (shaded by the inclined anode from the discharge column) molecules could enter from the fore-vacuum region into the high-vacuum region and could not be ionized on their path. By measurement it was actually found that in this case the value of the pressure in the high-vacuum region was almost equal to the pressure in the outlet openings. This effect could not be attained if the evacuation was based on sorption processes.

I wish to acknowledge the help given by Prof. V. Kunzl and Dr. L. Eckertová, of the Department of Electronics and Vacuum Physics, in the preparation of this communication for publication.

Optical Scanning of Liquid Concentration in Flow Studies with Porous Models

It is often convenient to employ laboratory models for the study of fluid behaviour in oil reservoirs. Typical experiments may concern the flow of two liquids miscible with one another. Basically, this calls for measurements of concentration as a function of time and position. If the liquids can be distinguished by some parameter, a corresponding method of observation may suggest itself. Thus, Beran[1] employed radioactively tagged liquids in his models, while Rifai[2], de Josselin de Jong[3] and others measured the electrical conductivity of salt solutions flowing through packed beds.

Such methods have the advantage of allowing the entire model to be monitored, but they suffer in varying degrees from lack of resolution. The porous medium is generally simulated by a packing of granular material. Retention of a realistic permeability requires that the grains be kept relatively fine; hence the main obstacle to optical scanning resides in the fact that thick packings are normally opaque.

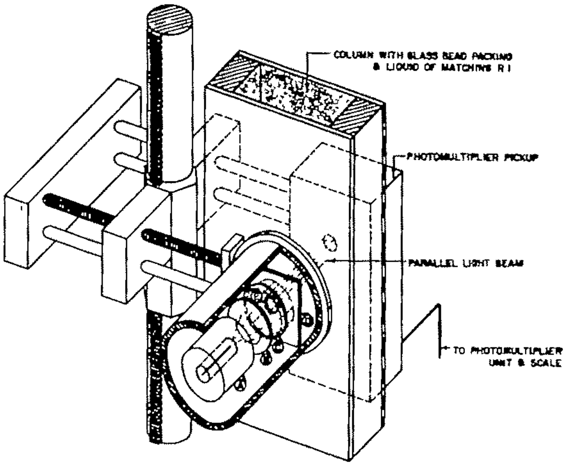

Fig. 1. Scanning unit for dispersion studies. *A*, Point source; *B*, heat filter; *C*, lens; *D*, interference filter; *E*, exit stop

In the method here described, the refractive indices of liquid and packing substance are chosen to be identical at the laboratory temperature, thus enabling a three-dimensional model to transmit light. Optically matched systems of this kind are called Christiansen filters[4,5], and are essentially a suspension of low-dispersion particles, for example, optical glass, in a highly dispersive liquid. Light transmission will be restricted to a narrow range of wave-lengths at the intersection of the two dispersion curves. The system thus acts as a monochromator the region of transmissivity of which will shift if the temperature of the liquid is changed.

In the present arrangement (Fig. 1) the above principle applies with changed emphasis. Thus, the light is rendered monochromatic prior to entry into the flooded model, which is maintained at constant temperature. At the exit face, the pencil passes through a narrow aperture into the photomultiplier unit, which registers constant intensity in the presence of a single liquid phase. When two inter-miscible liquids are under study, one of the components is identified by a dye, thus allowing concentration profiles in the mixing zone to be mapped colorimetrically.

A number of applications of the Christiansen system to model studies have been suggested (Steber and Marsden[6], van Meurs and van der Poel[7], Heller[8]). The last-named employed a matrix of ground crystalline calcium fluoride, which offers the advantages of a low refractive index ($n_D = 1 \cdot 4338$) and optical isotropy. Spherical glass beads have been chosen here as an alternative packing material, being hard, chemically inert and available in bulk, besides offering surfaces which may be readily conditioned from water-wet to oil-wet preference. Anisotropy, however, now arises due to small deviations between spheres, of the order of 0·001 unit from the mean refractive index. In the present model (Table 1), where the search beam axis may cut as many as 300 glass-liquid interfaces, the above variation will suffice to cause scattering and absorption of most of the incident light. This disadvantage has been rendered unimportant by prefiltering, careful collimation and use of a sensitive detector.

The container was assembled from plates of '*CR*-39' ('Homalite') thermosetting plastic. Set up vertically, the column is first flooded with clear

liquid (Table 1). In the simpler initial experiments this is displaced with an identical mixture, which in addition carries oil-soluble dye. Both phases are injected through a two-chamber unit at the base, designed to produce at time zero of the experiment a sharp and level interface between the two liquids.

The light from an argon-sealed arc is rendered yellow by a Bausch and Lomb transmission-type interference filter, with peak at 5890 Å. and half-width 80 Å. The collimated pencil is about 1·8 mm. in diameter, that is, one order of magnitude larger than the glass beads. A much narrower beam would probably register local inhomogeneities in the matrix. Lamp and photomultiplier pick-up move as a unit for scanning along two co-ordinates (Fig. 1), thus allowing transverse as well as longitudinal dispersion to be monitored in models of suitable width.

Finally, the necessary temperature control may be deduced from a curve of relative beam intensity I/I_0 versus temperature T of the clear liquid, with maximum brightness at the matching value (25° C). It is more convenient first to plot the variation of I/I_0 as a function of refractive index, with T constant. This has been done by mismatching clear mixtures in the porous model, and using the temperature gradient, $\Delta n/\Delta T$ (Table 1), to convert the result into the required curve (Fig. 2). In our arrangement, an increase in dye concentration (c) from 50 to 51 per cent will reduce I/I_0 by 1·7 per cent, and this in turn corresponds to a temperature fluctuation of less than 1° C. In a typical mixing zone of 10 cm. length (c = 10–90 per cent), the colour contrast involved should be just observable. Consequently, temperature errors of ±1° C. or more affect the measurements and must be avoided through suitable controls.

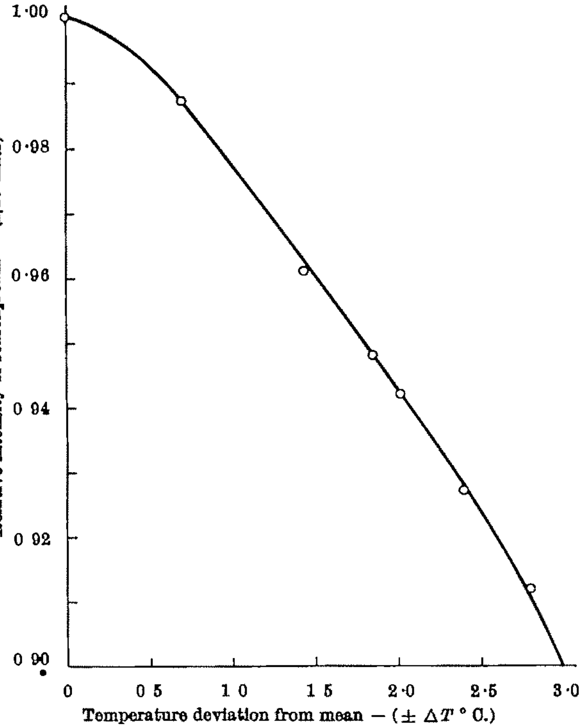

Fig. 2. Reduction in the brightness of the search beam due to temperature deviations from the matching value (for $n_D^{25} = 1·5408$)

The method is adaptable to a variety of interesting problems in reservoir physics; but it will be applied initially to a theoretical study of miscible flow. Solutions to the differential equations of two alternative statistical models are available[9], and the experimental method described should be well suited to furnish the data on which to base a decision.

I am indebted for much valuable advice to Mr. J. W. Young, manager of production research, Imperial Oil, Ltd., Calgary, and Prof. H. E. Gunning of the Chemistry Department, University of Alberta, Edmonton. My thanks are also due to Dr. W. N. McKay, of this Laboratory, for the viscosity determination quoted in Table 1.

Gallium Arsenide Tunnel Diodes

ESAKI, or tunnel, diodes[1-3] in gallium arsenide have been made in this Laboratory. Zinc-doped gallium arsenide was prepared by diffusion to give a concentration of 9×10^{19} impurity atoms/cm.^{3} and tin pellets were alloyed on to this material to form a junction. The diameter of the pellets varied from 0·003 to 0·015 in.

Diodes made in this manner have shown negative resistances of between 0·1 Ω and 4 Ω, with a wide range of peak currents from 70 m.amp. to 7 amp. The highest ratio of peak to valley currents observed was 30 : 1, and the average value was about 15 : 1. The voltages at which the peak and valley currents occurred were not constant but varied from device to device, from 0·13 to 0·50 V. for the peak current, and from 0·35 to 0·55 V. for the valley current. These variations can be partially explained by the presence of series resistance of about 0·1 Ω, probably in the contacts to the devices.

The diodes were found to switch across the unstable negative resistance region in a time of less than 1 mμsec., this being the limit of the measuring equipment. When the diodes were mounted in a strip-line designed to resonate at a frequency of about 400 Mc./s., relaxation oscillations were observed. The fundamental frequency varied with d.c. bias voltage over the range 300–560 Mc./s. and in all cases harmonics were seen up to 1 kMc./s., which was the upper limit of the receiver. 5 milliwatts output power was obtained.

We wish to thank the Admiralty for permission to publish this communication.

GEOPHYSICS

Micropulsations in the Earth's Magnetic Field Simultaneous with Pulsating Aurora

Some preliminary results have been obtained from an investigation being undertaken at College, Alaska, concerning the correspondence of the Earth's magnetic field micropulsations[1] with pulsating aurora for the purpose of explaining the physical mechanism giving rise to the phenomena. Fig. 1 illustrates the nightly coincidence of micropulsations, measured with a 6-ft. diameter magnetic north axis loop antenna of 21,586 turns and 3914-Å. auroral pulsations from 70° of sky measured with a lens, interference filter, photo-multiplier system. Fig. 2 shows an occasion of simultaneous oscillations from the two phenomena.

Messrs. A. Belon, C. Deehr, M. Rees and G. Romick, of the Geophysical Institute Optics Division, have aided me in the development of the experiments.

An Expanding Earth with Loss of Gravitational Potential Energy

Recently, and independently, Carey[1] and Heezen[2] have concluded that the Earth is expanding. The first question asked of such a hypothesis usually takes the form of an inquiry as to the source of energy for such an expansion. This question is based on the assumption that the gravitational potential energy of the Earth is inversely proportional to its radius, and the assumption in turn is presumably based on the well-known equation (see, for example, Loney's "Statics", p. 359).

$$E = -\frac{3}{5}\frac{GM^2}{a}$$

where E is the gravitational potential energy, G the gravitational constant, M the mass and a the radius of the Earth. However, the equation refers only to a sphere of uniform density, and one possibility that appears to have been overlooked is that a non-uniform Earth can expand and lose gravitational potential energy at the same time.

The following expressions for density ρ_r versus radius r in the Earth have been obtained by fitting linear density distributions of the form: $\rho_r = \rho_0(1 - kr)$ to each section of Bullen's[3] model B of the Earth:

$0 < r < 1{\cdot}250 \times 10^8$ cm.	$\rho_r = 17{\cdot}900(1 - 1{\cdot}29162 \times 10^{-9} r)$
$1{\cdot}250 < r < 1{\cdot}389$,,	$\rho_r = 42{\cdot}078(1 - 5{\cdot}14625 \times 10^{-9} r)$
$1{\cdot}389 < r < 3{\cdot}471$,,	$\rho_r = 13{\cdot}408(1 - 7{\cdot}53631 \times 10^{-10} r)$
$3{\cdot}471 < r < 6{\cdot}291$,,	$\rho_r = 7{\cdot}505(1 - 7{\cdot}69678 \times 10^{-10} r)$
$6{\cdot}291 < r < 6{\cdot}338$,,	$\rho_r = \text{constant} = 3{\cdot}34$
$6{\cdot}338 < r < 6{\cdot}371$,,	$\rho_r = \text{constant} = 2{\cdot}79$

If spherical symmetry is assumed these distributions give the right mass, $5 \cdot 977 \times 10^{27}$ gm., and a slightly high moment of inertia, $8 \cdot 120 \times 10^{44}$ gm. cm.^{2}; the discrepancy between this value and the generally accepted one is immaterial for the purposes of the present argument. The gravitational potential energy of an Earth with the above density distributions is $- 2 \cdot 47949 \times 10^{39}$ ergs.

If in the past the density distribution in the Earth was of the form $\rho_r = \rho_0(1 - kr^2)$ from $0 < r < a$, where a is its past radius, then assuming that the mass has remained constant and that the surface density of the Earth was $2 \cdot 85$ gm. c.c.$^{-1}$, one model with a higher potential energy but a smaller radius than the present Earth is $a = 6 \cdot 27 \times 10^8$ cm. and $\rho_r = 10 \cdot 197(1 - 1 \cdot 83275 \times 10^{-18} r^2)$. The potential energy of this model is $-2 \cdot 47464 \times 10^{39}$ ergs and its moment of inertia is $8 \cdot 036 \times 10^{44}$ gm. cm.^{2}. If there are no external or internal sources of energy the Earth will tend to proceed from a higher state of potential energy to a lower state, and one way it could do this would be to expand to its present form. Thus expansions of the order of 100 km. seem quite possible without postulating any source of energy. The Earth will, in fact, lose energy during the expansion.

If it is assumed that the mass of the Earth has remained constant and that $\rho_a = 2 \cdot 85$ gm. c.c.$^{-1}$ then Earth models of smaller radii but higher potential energies can be found for any value of $n \geqslant 1$, where $\rho_r = \rho_0(1 - kr^n)$. The higher the value assumed for n the greater is the possible expansion. Furthermore, for each value of n the range of models with likely density distributions covers models with higher or lower moments of inertia than the present Earth. If density distributions which, on present evidence, seem improbable are postulated, then expansions of the order of 1,000 km. are possible. Expansions are also possible even if the region $0 < r < 3 \cdot 471 \times 10^8$ cm. is kept constant and only the mantle and crust are changed.

In this communication no attempt has been made to postulate possible mechanisms. These, and other possible models, will be discussed in a fuller account elsewhere.

BIOPHYSICS

Effect of Ultra-violet Light on the Shape and Size of Deoxyribonucleic Acid

SEVERAL investigators[1,2] have found that the viscosity of solutions of deoxyribonucleic acid is reduced by irradiation with ultra-violet light of 254 mμ. This change could be the result either of main-chain scission which reduces the length of the molecules or of an increase in flexibility which allows the molecule to take up a more coiled configuration and thereby reduces the volume occupied in solution, as measured by the radius of gyration.

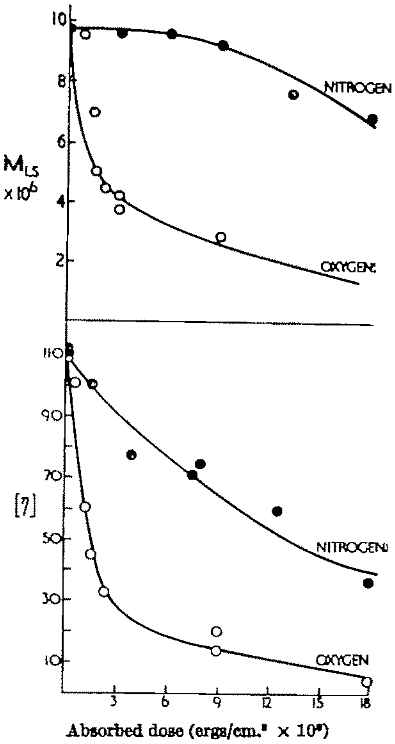

Fig. 1. Changes in the weight average molecular weight (M_{LS}) and in the intrinsic viscosity ([η] in dl./gm.) of deoxyribonucleic acid following irradiation with ultra-violet light of 254 mμ at the rate of 1×10^4 ergs/cm.^{2}/sec. The polymer was at a concentration of 0 01 gm./dl. and either oxygen or purified nitrogen was bubbled through the solution before and during the irradiation

We have carried out simultaneous measurements of the molecular weight by light scattering and of the viscosity in a Couette viscometer on solutions of deoxyribonucleic acid irradiated with a 44-watt 'Hanovia 769/67' mercury resonance lamp in a 'Vycor' envelope. The water-cooled irradiation vessel was specially constructed to allow total immersion of the lamp in the deoxyribonucleic acid solution and gas bubbling through the solution during the irradiation. The deoxyribonucleic acid was obtained from viable salmon sperm and contained less than 0·1 per cent of protein. Different preparations, varying in molecular weight, were used for the experiments shown in Fig. 1 and in Table 1. All measurements were made in 0·2 *M* saline containing citrate buffer.

Fig. 1 shows that, in the absence of oxygen, the first effect of ultra-violet light of 254-mμ wavelength is to reduce the viscosity without altering the molecular weight. As the dose is increased the molecular weight falls, showing that the molecule is severed, but the principal effect remains one of coiling.

If oxygen is present, then the molecular weight falls immediately; but the change in viscosity is very much greater than that due to the reduction in molecular weight alone. The introduction of oxygen gives rise to a second process, main-chain scission, without decreasing the amount of coiling that is produced when the irradiation is done under pure nitrogen.

This oxygen effect is not due to attack by ozone since the 'Vycor' filter effectively excludes the oxygen-

Table 1. Effect of Added Substances on Ultra-violet-induced Changes of Molecular Weight (M_{LS}) and Radius of Gyration (ρ_z in Å.) of Deoxyribonucleic Acid

Dose (ergs/cm.^{2} × 10^6)	No additive		Dimethylaniline 10^{-4} M		Glutathione 10^{-4} M		Glucose 10^{-1} M		Catalase 0·01 per cent	
	M_{LS}	ρ_z	M_{LS}	ρ_z	M_{LS}	ρ_z	M_{LS}	ρ_z	M_{LS}	ρ_z
None	6·7	2,420	7·7	2,600	6·3	2,400	6·3	2,420	7·7	2,400
14 (Nitrogen)	6·0	1,240	5·7	1,370	6·1	1,570	5·5	1,450	7·7	1,750
3·6 (Oxygen)	2·5	1,060	5·7	1,980	5·1	1,610	7·3	2,120	4·5	1,850

absorbing bands of ultra-violet light. Experiments in which oxygen that had been passed over the 'Vycor' lamp and was then bubbled through a solution of deoxyribonucleic acid failed to reveal any degradation.

Coiling of deoxyribonucleic acid is produced when the specific hydrogen bonding between the bases in the twin helix is disrupted[3]. Our results would suggest that this structure is disorganized by ultra-violet light before there is any extensive photochemical degradation of the bases. Internal conversion can lead to the degradation of excitation energy to thermal energy, and it would appear that the increase in the oscillational degrees of freedom brings about this change of shape. Photolysis of the pyrimidine or purine bases would not decrease the molecular size except by initiating further reactions such as hydrolysis.

Direct interaction between an oxygen molecule and the singlet excited state to form peroxides which are further decomposed by the ultra-violet light can best explain the main-chain scission in the presence of oxygen. Photochemically produced OH radicals have been shown[4] to reduce the viscosity of solutions of deoxyribonucleic acid and we were able to show by light-scattering measurements that this effect was due mainly to main-chain scission.

Dimethylaniline, glutathione and glucose were all found to protect the molecular weight and radius of gyration of the irradiated deoxyribonucleic acid against the oxygen effect (see Table 1), presumably by competitively reacting with the degradative free radicals produced via the peroxide. Protection by catalase was observed and is probably due to the decomposition of the peroxide in such a way that it does not give rise to degradative free radicals. Poisoning of the catalase by potassium cyanide caused a loss in protective activity. In the absence of oxygen none of these substances reduced either the coiling or the main-chain scission process significantly, except, oddly, catalase.

A puzzling feature is that the biological effects produced by ultra-violet light have not been found to be influenced by oxygen. Possibly cell constituents act as protective agents, and from this it would follow that cellular lesions in so far as they are due to attack on deoxyribonucleic acid follow from an interference with the hydrogen bonding between the bases and not from a degradative reaction. Doses needed to produce detectable coiling are very large when compared with those necessary to produce changes in cells. Probably the number of hydrogen bonds that have to be broken to produce sufficient coiling to be measured by physicochemical techniques is very much greater than that necessary for interfering with the biological function of deoxyribonucleic acid.

Blood Flow through Narrow Tubes

In the course of an extensive investigation (with Prof. A. C. Burton at the University of Western Ontario) of the hæmodynamics of perfused vascular beds, it was found necessary to examine the somewhat simpler case of blood flow in narrow glass tubes. Accordingly, the pressure-flow curves in tubes of radii 50–750μ for human erythrocytes suspended in standard acid–citrate–dextrose were measured at 25·5° C. over a wide range of hæmatocrits[1–4]. A typical set of such pressure-flow curves is shown in Fig. 1. The curves were found to approach linearity at moderate flow rates; if the linear segments are extrapolated back, they intersect the positive pressure axis at finite values and then converge to a common 'nodal point' on the negative flow axis. However, in the non-linear region at very low flow rates, the curves appear to converge toward the origin. There is no evidence of any yield stress or intercept on the positive pressure axis. All the curves can be represented by an equation of the form:

$$\dot{Q} = MP - B[1 - \exp(-kP)] \qquad (1)$$

where $\dot{Q}$ is the volume rate of flow and P the pressure gradient; the parameters M and k depend on both tube radius and hæmatocrit, whereas the nodal point B depends only on the tube radius[3]. Pressure-flow curves of similar shape have been obtained by other workers and can be inferred from the apparent viscosity data of Kümin[5].

The results obtained from the basic pressure-flow measurements were used to plot the rate of shear at the wall versus the shear stress (consistency curves). It can be shown[2] that the shear-rate is given by:

$$F = \frac{1}{\pi R^3}\left[3\dot{Q} + P\frac{d\dot{Q}}{dP}\right] \qquad (2)$$

$$\text{or:} \quad F = \frac{4\dot{Q}}{\pi R^3} + \frac{B}{\pi R^3}\left[1 - (1 + kP)\exp(-kP)\right] \qquad (3)$$

and can be plotted from (3) as a function of the shear stress $PR/2$. The first term in (3) is the shear-rate

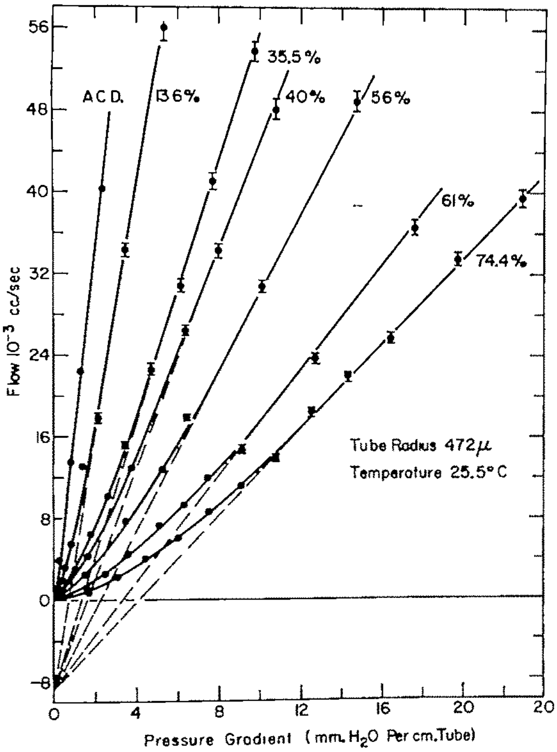

Fig. 1. Pressure-flow curves for human red cells suspended in acid–citrate–dextrose for various hæmatocrits as indicated in volume per cent

for a Newtonian liquid while the second term arises from the non-linearity of the pressure-flow curves. A set of such consistency curves for three hæmatocrits is shown in Fig. 2. They have approximately the same shape as the pressure-flow curves, and become linear at shear stresses greater than about 20 dynes/cm. From the data of Kumin[5], it is possible to plot what might be called the 'apparent shear rate' as a function of shear stress as shown in Fig. 3. This is a plot of the usual consistency variables (for a fluid that obeys Poiseuille's law), so that the contribution of the second term in equation 3 is not present. The error introduced by this approximation is less than 10 per cent, and it does not affect the basic curve shape. The important features of all these curves are the non-linearity below about 20 dynes/cm., and the absence of any finite intercept on the stress axis.

Equation 1 can be given a phenomenological interpretation by assuming that the fractional change in differential fluidity is proportional to the change in shear stress[4]. Such a fluidity change can be interpreted physically as a structural re-organization of the fluid with increasing flow-rates that arises from the axial accumulation of the red cells in a variable shear field[2].

The Fahraeus–Lindqvist effect appeared very prominently in the data of Kümin[5] and also in our own experiments[3,4]. The tube radius at which the apparent viscosity is reduced 10 per cent below the asymptotic value for large tubes was found to vary from 130μ at 10 per cent hæmatocrit to 633μ at 80 per cent. If the effect is interpreted as a sigma phenomenon[6], the average thickness of the unsheared laminæ was found to vary from 3·5μ at 10 per cent hæmatocrit to 34μ at 80 per cent. If, on the other hand, the effect arises from the presence of a cell-free marginal zone[7,8], it was found that its thickness must be 6μ at 10 per cent hæmatocrit, 3μ at 40 per cent, and only 1·5μ at 80 per cent. Such a cell-free marginal zone could also result from the axial accumulation of the red cells. It is difficult to determine the relative importance of the marginal zone and the

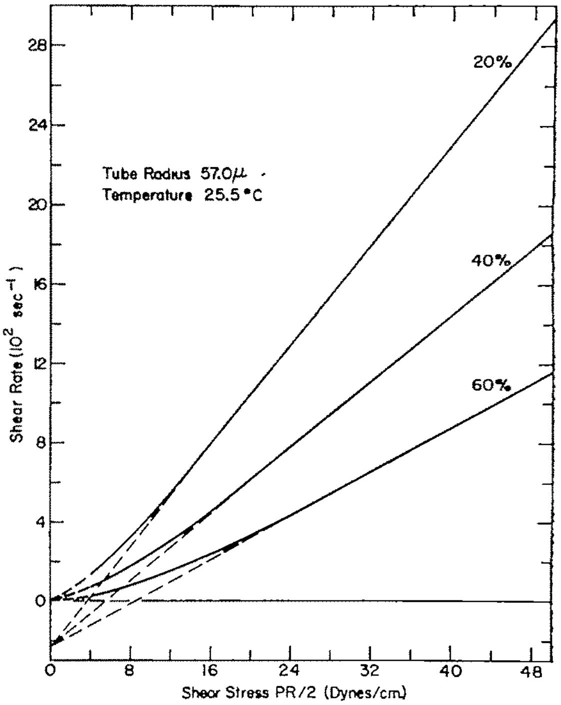

Fig. 2. Consistency curves for human red cell suspensions of three hæmatocrits. The broken curves near the origin represent the only extrapolation beyond the measurements

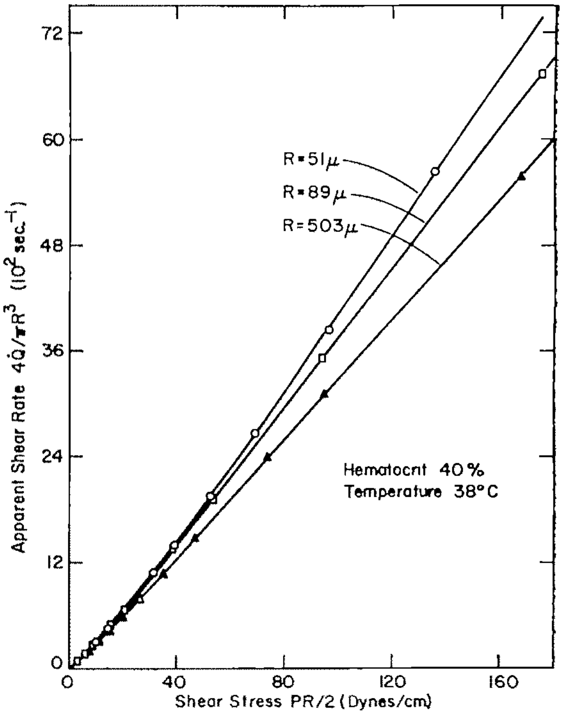

Fig. 3. Consistency curves for defibrinated ox blood calculated from data of Kumin

sigma phenomenon in producing the Fahraeus–Lindqvist effect.

On the basis of some measurements of A. L. Copley, Scott Blair[9] and Reiner and Scott Blair[10] have recently suggested that the rheological properties of blood can be described in terms of a theory put forward by Casson[11] for varnish and ink. This theory is applicable to substances the consistency curves of which intersect the stress axis at a yield value. However, the consistency curves which we have obtained for blood do not seem to intersect the stress axis at a finite value, but rather become non-linear below 20 dynes/cm. and point toward the origin. The lowest shear stress that was reached in Copley's measurements was 100 dynes/cm., and so the non-linearity of the consistency curves was not detected. Thus it does not appear that Casson's theory would provide a satisfactory description of the flow properties of blood at very low shear stresses if no yield value exists.

I wish to thank Dr. M. G. Taylor, now at the University of Sydney, for several helpful discussions, and Mr. J. E. Baptist, of this laboratory, for his help with the calculations.

CHEMISTRY

Crystal Spectrum of Copper Biguanides

IN a previous communication[1] it was shown that the absorption spectrum of a microscopic crystal of copper-ethylene-diamine-*bis*(acetylacetone) consists of three bands as predicted by the ligand field theory. Copper biguanides form transparent reddish crystals[2], very convenient for measurement in our experimental arrangement. In Fig. 1 are given the spectrophotometric optical density (*O.D.*) vs. wave-length (λ) curves for a thin crystal of copper *bis*-biguanide dibromide dihydrate with light polarized along the long axis of the crystal and at right angles to it, respectively. It is evident that the first curve consists of three bands, but the sharpness and fine structure are not as well defined as was the case with copper-ethylene-diamine-*bis*(acetylacetone). The decomposition of the curve into its component bands shows three peaks at 485 mμ, 540–550 mμ and 600 mμ. When the light was polarized at right angles to the long axis of the crystal, the absorption spectrum was found to consist of two bands, with peaks at 485 mμ and 550 mμ, the peak at 600 mμ being missing. If we associate the band of longest wave-length with the transition $d_{z^2} \rightarrow d_{xy}$, then the result may mean that the *z*-axis of the molecular field coincides with the long axis of the crystal.

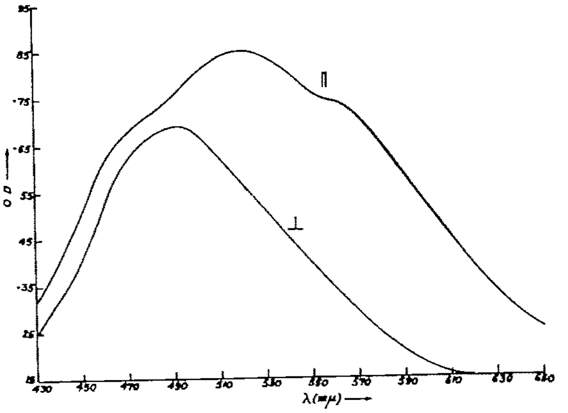

Fig. 1

The crystal spectrum of the chloride and also of the fluoride was found to be identical with that of the bromide, indicating that the anion was outside the co-ordinating sphere and had no perturbing action on the copper *d*-orbitals, which is also corroborated by the chemical properties[2]. In solution, all these compounds have one broad absorption band and show no structure resembling a crystal spectrum. Further, the structure could be detected with extremely thin crystals only. As the thickness of the crystal was increased, the structure of the band became increasingly less well defined.

Structure of Lithium Methoxide

RECENTLY, Bradley has proposed a theory which correlates and predicts the structures of metallic alkoxides[1]. At the moment, Bradley's theory cannot be fully developed because of the lack of direct structural information. In particular, it is not known whether lithium methoxide is ionic, as generally assumed, or whether it is a giant polymer[2]. This communication describes the structure of lithium methoxide, which is shown to be similar to that of lithium hydroxide[3]. Although the structure has some features reminiscent of a giant two-dimensional polymer, it would normally be considered ionic.

Lithium methoxide was prepared by solution of the metal in methanol. Excess methanol was pumped off, and specimens of the resultant powder transferred to thin-walled 'Pyrex' capillaries which were sealed with 'Picien' wax. All operations were carried out in a dry box. Powder photographs were taken with a 3-cm. 'Unicam' oscillation camera. The photographs showed that the unit cell was tetragonal with $a = 3{\cdot}55_5$ and $c = 7{\cdot}68_7$ Å. Systematic absences corresponded to the space group *P4/nmm* (No. 129). The density calculated on the assumption of two formula units in the cell was 1·30 gm./c.c. The observed density, which could not be accurately determined because the powder was so hygroscopic, lay between 1·2 and 1·5 gm./c.c. The lithium ions lie at $\pm(\frac{1}{4}, \frac{3}{4}, 0)$, the oxygen atoms at $\pm(\frac{1}{4}, \frac{1}{4}, u_1)$, and the carbon atoms at $\pm(\frac{1}{4}, \frac{1}{4}, u_2)$. The methoxide ion has four-fold symmetry so that the hydrogen atoms, which were ignored in the analysis, presumably adopt a statistical arrangement to conform with this symmetry. The parameters u_1 and u_2 were determined by trial and error and found to be $0{\cdot}10_5$ and 0·29 respectively. Thus the O—CH_3 distance is 1·42 Å.

If the structure is viewed in a direction normal to the four-fold axis, it is seen to consist of layers *ABCBAABCBA* . . . , with $A = CH_3$, $B = O$ and $C = Li$. The methyl groups are separated by 4 09 Å. in the [*c*] direction and by only 3·55 Å. in the [*a*] and [*b*] directions. The oxygen atoms are bonded to a methyl group on one side and are co-ordinated to four lithium ions on the other to form square pyramids with oxygen atoms at the centre. The Li . . O distance is 1·95 Å. and the LiOLi angle 80·3°. The lithium ions are surrounded by a tetrahedron, flattened in the [*c*] direction, of oxygen atoms. The OLiO angles are 131·1° and 101·7°. The Li . . Li distance is 2·51 Å. and the nearest O . . O contact 2·99 Å. The $LiOCH_3$ angle is 114·5°.

A full account of this work and of further physicochemical measurements on this and other alkali metal methoxides will be published elsewhere.

New Univalent Cobalt Complexes of the $[Co^{I}(CN)_5X]$ Type

Hume *et al.*[1] found that the aquopentacyanocobaltate(III) and cobaltate(II) complexes were irreversibly reduced in one step to the cobalt(I) state polarographically in the cyanide medium, and the cobalt(I) complex was neither reducible nor oxidizable at the dropping mercury electrode.

Recently, the similar cobaltate(III) complexes of pentacyano type, $K_{2+n}[Co^{III}(CN)_5X]$, were also found to be reduced irreversibly in one or two steps to the univalent cobalt complexes at the dropping mercury electrode[2], where X denotes the ligand, Cl^-, Br^-, I^-, SCN^-, N_3^-, $S_2O_3^{2-}$, NO_2^-, or SO_3^{2-}.

In order to clarify the structure and the co-ordination number of this univalent cobalt complex, a number of attempts have been made to isolate the complex from the solution, but have failed mainly due to the great solubility of the complex in alcohol and water.

From the following two reasons, however, it was concluded that the univalent cobalt complex has a similar structure to the original oxidized form, that is, the hexa-co-ordinated formula, $[Co^{I}(CN)_5X]$.

(1) It was ascertained in advance polarographically that the yellow solution of the univalent cobalt complex was easily obtained from the reduction of the pentacyanocobaltate(III) ion by 3 per cent sodium amalgam in an atmosphere of nitrogen. No deposition of metallic cobalt was found in any case. From this solution of the cobaltate(I) complex, the pentacyanocobaltate(II) complex, $K_3[Co^{II}(CN)_5]\cdot H_2O$ (ref. 3), was always isolated in an atmosphere of nitrogen as bright violet crystals by addition of ethanol in portions with respect to all the pentacyanocobaltate(III) complexes. This fact means that the pentacyano structure was not destroyed and was still maintained in the univalent cobalt complex.

(2) Generally, all these cobaltate(I) complexes were oxidized by air to the cobalt(III) state on exposure. By pursuing the increase of the wave-height with time, however, it was found that there existed considerable differences among the rates of oxidization, depending upon the kind of ligand, X. For example, the cobaltate(I) complex obtained from the reduction of azido- or nitro-pentacyanocobaltate(III) ion was seen to be instantly oxidized to the cobalt(III) state, on being exposed to the air. On the other hand, the oxidation-rate of the cobaltate(I) complex obtained from the other pentacyanocobaltate(III) ions was found to be small, though the cobaltate(I) complex was still oxidized slowly in open air. This fact implies that the sixth ligand, X, is still co-ordinated about the central cobalt(I) atom in the univalent cobalt complex.

The re-oxidized product obtained from these univalent cobalt complexes was also identified as a hydroxypentacyanocobaltate(III) complex, $K_3[Co^{III}(CN)_5OH]$ (yellow crystals). This is due to the alkalinity which resulted from the sodium amalgam used. Therefore, the bond between Co^{I} and the sixth ligand, X, is considered not to be so strong. Hence, in a solid state, it might be possible that the penta-co-ordinated complex, $K_4[Co^{I}(CN)_5]$, can exist rather than the hexa-co-ordinated complex, $K_4[Co^{I}(CN)_5OH_2]$, being considered analogous to the case of the penta-*iso*nitrilo complexes[4], $[Co^{I}(NCR)_5]Y$ (yellow crystals), where R indicates phenyl-, *p*-tolyl-, or *o*-tolyl-radical and Y, the ion, ClO_4^-, I^-, NO_3^-, or ClO_3^-.

Accordingly, the processes of the electrode reaction for the pentacyanocobaltate(III) complexes were considered to be as follows. For the halogeno complexes:

$$
\begin{array}{llll}
[Co^{III}(CN)_5X]^{3-} + e^- & \longrightarrow & [Co^{II}(CN)_5X]^{4-} & \text{1st step} \\
[Co^{II}(CN)_5X]^{4-} + e^- & \longrightarrow & [Co^{I}(CN)_5X]^{5-} & \text{2nd step} \\
[Co^{I}(CN)_5X]^{5-} + H_2O & \longrightarrow & [Co^{I}(CN)_5OH_2]^{4-} + X^- & \\
 & & X = Cl^-, Br^-, I^- &
\end{array}
$$

For the thiocyanato complex (in the pentacyano complex, $K_3[Co(CN)_5SCN]$, the ligand, SCN^-, is bound to the central cobalt(III) atom by sulphur, while in the ammine complexes, for example $[Co(NH_3)_5NCS]Cl_2$, the ligand, NCS^-, is co-ordinated by nitrogen atom. Therefore, in this case, the equation of the complex can scarcely be considered):

$$
\begin{array}{llll}
[Co^{III}(CN)_5SCN]^{3-} + e^- & \longrightarrow & [Co^{II}(CN)_5SCN]^{4-} & \text{1st step} \\
[Co^{II}(CN)_5SCN]^{4-} + e^- & \longrightarrow & [Co^{I}(CN)_5SCN]^{5-} & \text{2nd step}
\end{array}
$$

For the azido-, nitro-, thiosulphato- and sulphito-complexes:

$$
[Co^{III}(CN)_5X]^{(2+n)-} + 2e^- \longrightarrow [Co^{I}(CN)_5X]^{(4+n)-} \quad \text{1st step}
$$

$$
X = N_3^-, NO_2^-, S_2O_3^{2-}, SO_3^{2-}
$$

The resulting pentacyanocobaltate(I) complexes did not give the anodic wave at all. Namely, all the above electrode reactions are irreversible polarographically, though the reversibility of the reduction waves looks fairly large in appearance.

The mechanism of the electron transfer and the electronic configuration for the above reactions are believed to be as follows. The acceptance of the electrons occurs in two stages:

$$d^2d^2d^2[D^2SP^3] \xrightarrow{\bar{e}} d^2d^2d^2[D^2SP^3]d^1 \longrightarrow$$

$$d^2d^2d^2d^1[DSP^2PD] \xrightarrow{\bar{e}} d^2d^2d^2d^2[DSP^2PD]$$

First, the electron is accepted into the 4*d* peripheral orbitals temporarily, where it is held loosely, since the 3*d* atomic orbitals of Co(III) atom are fully occupied. After that the consecutive change of the electronic configuration and the placement of the electron in the stable 3*d* orbitals occur slowly. Therefore, this electrode process requires fairly high overpotential. In the second stage, the electron is accepted into the vacant 3*d* orbital directly. Thus, the difference of the electronic configuration in the oxidized and the reduced forms is considered to be one of the main causes for irreversibility of the electrode reactions.

I wish to thank Prof. R. Tsuchida for helpful discussions.

Carbonates of Uranium

MILLER and co-workers[1] for the first time isolated uranyl carbonate, prepared by the action of carbon dioxide under pressure on uranium trioxide, ammonium and sodium uranates. A different process was followed by Chernyaev and co-workers[2], who prepared the compound by the treatment of aqueous and alcoholic solutions of uranyl nitrate with carbon dioxide under pressure or aqueous suspensions of uranium oxide, UO_2, under normal conditions. A simple and convenient method has been developed by us for the preparation of the compound. The hitherto unreported compound uranium (IV) oxycarbonate, the preparation of which is described below, on exposure to dry air undergoes simultaneous oxidation and dehydration, resulting in the formation of the compound UO_2CO_3, 2·5 H_2O, the progress of the oxidation being indicated by the gradual change of colour from dark green to bright yellow. This hydrated uranyl carbonate, when heated *in vacuo* at 160°, gives the anhydrous compound UO_2CO_3, which is stable up to 500° C.

Uranyl ion undergoes photoreduction when exposed to sunlight in the presence of reducing agents such as alcohol or formic acid. When ammonium carbonate is added to a photochemically reduced solution of uranyl nitrate or formate, a green precipitate is obtained in a fine state, which on washing turns dark green. Analysis of the freshly prepared moist compound was carried out after ammonia had been tested for and found to be absent. The uranium to carbonate ratio was found to be 1 : 1 by semimicro-combustion method. The water content was found to vary from time to time due to the moist compound being used for analysis. The total uranium content was estimated as U_3O_8 and also by the Jones reductor method. That all the uranium exists as uranium (IV) was proved by directly titrating the solution of the compound in 2 *N* sulphuric acid against standard potassium permanganate. On account of the extreme proneness of the compound to oxidation and hydrolysis at high temperature, and also our lack of equipment for isothermal dehydration at low temperature, it has not been possible to get the compound either in the anhydrous state or in a definite state of hydration.

The isolation of uranium (IV) oxycarbonate offers a new route for the syntheses of uranium (IV) compounds[3]. Investigations are proceeding with the view of preparing some new compounds of uranium as well as the dioxide[4].

Photolysis of 1 : 3-Dichlorotetrafluoroacetone

THE primary act in the photolysis of acetone at room temperature has been shown by a number of workers to be the production of an acetyl and a methyl radical[1]. It is believed that the photolysis of hexafluoroacetone is a simpler process in which only trifluoromethyl radicals and carbon monoxide are formed[2]. Hexafluoroacetone is thus an unambiguous photochemical source of trifluoromethyl radicals, and the close structural similarity of 1 : 3-dichlorotetrafluoroacetone has prompted an investigation into its suitability as a source of difluorochloromethyl radicals.

The near ultra-violet absorption spectrum of 1 : 3-dichlorotetrafluoroacetone shows a broader and more intense band than does that of acetone ($\lambda_{max.}$ 2,900–3,100, $\epsilon_{max.}$ 80, cf. acetone $\lambda_{max.}$ 2,700–2,800, $\epsilon_{max.}$ = 16). A preliminary study of the photolysis of this ketone, at room temperature, using a high-pressure mercury lamp, has indicated that the primary step in this case is also dissociation into two identical radicals and a molecule of carbon monoxide. This conclusion is based upon the absence among the secondary products of reaction of any species which could have arisen from the difluorochloroacetyl radical, for example, tetrafluorodichlorodiacetyl.

The photodecomposition of dichlorotetrafluoroacetone is, however, more complex than that of hexafluoroacetone because the chlorodifluoromethyl radicals formed in the primary step are capable of abstracting chlorine atoms present in the undissociated ketone. Thus in the products of photolysis there appears, in addition to the *sym.*-dichlorotetrafluoroethane formed by the dimerization of chlorodifluoromethyl radicals, a smaller concentration of dichlorodifluoromethane. These two compounds have been isolated from the reaction products by means of gas chromatography, and their identity has been confirmed by comparison of their properties, including their mass spectrometric cracking patterns, with those of authentic samples. A third component of the products, also isolated by gas chromatography, is believed to be 1 : 3-dichlorohexafluoropropane on the basis of its retention volume and mass spectrum, but unfortunately no authentic sample of this material was available to confirm this. Mass spectrometric examination of the reaction mixture has revealed, in addition to mass peaks characteristic of the ketone and of the compounds named above, small mass peaks which can only arise from 1 : 4-dichlorohexafluoromethyl ethyl ketone, and from 1 : 4-dichloro-octafluorobutane. These overall reaction products may be understood on the basis of the following reaction scheme :

$$
\begin{aligned}
&ClCF_2COCF_2Cl \xrightarrow{h\nu} 2\,CF_2Cl— + CO\\
&CF_2Cl— + ClCF_2COCF_2Cl \rightarrow CF_2Cl_2 + ClCF_2COCF_2—\\
&CF_2Cl— + CF_2Cl— \rightarrow ClCF_2CF_2Cl\\
&CF_2Cl— + ClCF_2COCF_2 \rightarrow ClCF_2COCF_2CF_2Cl\\
&ClCF_2COCF_2CF_2Cl \xrightarrow{h\nu} CF_2Cl— + ClCF_2CF_2— + CO\\
&ClCF_2CF_2— + CF_2Cl— \rightarrow ClCF_2CF_2CF_2Cl\\
&ClCF_2CF_2— + ClCF_2CF_2— \rightarrow ClCF_2CF_2CF_2CF_2Cl
\end{aligned}
$$

The excited states involved in the primary decomposition of the ketone may be quenched by the ketone and by other molecules. The behaviour of the ketone in this respect resembles closely that of hexafluoroacetone. A further reaction product that is to be anticipated from the free radicals involved in this system is 1 : 6 dichloro-octafluoro-hexa-2,5-dione, which may be formed by the combination of two chlorotetrafluoro-acetonyl radicals. Although no evidence for the formation of this compound has been obtained, this does not exclude the possibility that it occurs in the products of reaction, since its observation may be made difficult by its anticipated relatively low volatility.

The proportion of dichlorodifluoromethane produced in the photolysis increases with temperature, and further study of this effect will give the energy of activation of the abstraction process.

Where radicals of two species, R_1 and R_2, are involved in a reaction system, these may combine in the following ways :

$$
\begin{array}{llll}
R_1 + R_2 \longrightarrow & \text{products :} & \text{rate constant} & k_{12}\\
R_1 + R_1 \longrightarrow & ,, & ,, \quad ,, & k_{11}\\
R_2 + R_2 \longrightarrow & ,, & ,, \quad ,, & k_{22}
\end{array}
$$

The quantity $\phi^2 = k^2_{12}/k_{11}k_{22}$ is a measure of the preference of unlike radicals to combine. For the chlorodifluoromethyl and 2-chlorotetrafluoroethyl radicals in the present system it has been possible to estimate the rates of accumulation of the ethane, propane and butane, which are formed by these processes, from the mass spectra of reaction mixtures photolysed to small extents. These give $\phi = 2{\cdot}2$, which is about the value required by the simple collision theory of reaction-rates, and is a value close to those tabulated recently for a number of free radicals[3].

Identification of the Structure of Non-volatile Organic Substances by Gas Chromatography of Pyrolytic Products

AT the Third International Symposium on Microchemistry in Birmingham, Prof. F. Feigl reported on the combination of coloured spot reactions with the pyrolysis of high molecular weight substances for identification purposes[1]. I wish to point out some new possibilities of this type of analysis in the study of the constitution of non-volatile or poorly volatile substances, combining pyrolytic reactions with gas chromatography.

Gas chromatography has been commonly used in the analysis of the products of pyrolytic processes. The work of Desty *et al.*[2] in following the function of internal combustion engines or of Kyryacos *et al.*[3] on the composition of the cool-flame products will be remembered. Recently, gas chromatography has been used for the analysis of substances by the examination of the functional groups split off, the determination of alkoxy-groups[4-6], for example. More recently, a short report on the analysis of pyrolytic products of some polymers[7,8] appeared in the literature.

The principle of the method proposed is very simple. The substance is submitted to controlled pyrolysis in a stream of carrier gas and the products produced are separated and identified by gas chromatography. It can be supposed that the composition of the pyrolytic products will bear a close relation to the structure of the original substance if the pyroly-

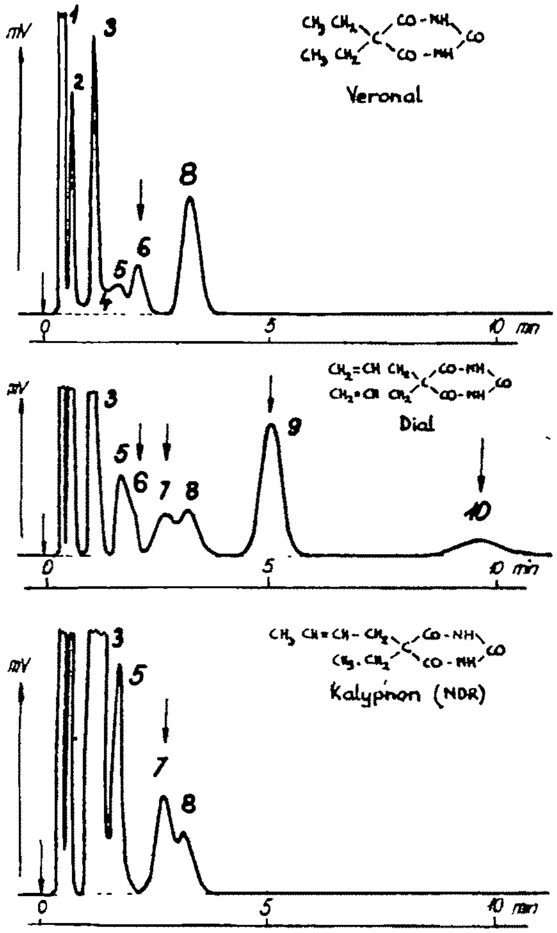

Fig. 2. Chromatograms of pyrolytic products in the area of C_1–C_6 hydrocarbon fragments of sodium salts of barbituric acid derivatives. Fraction 1, C_1 and C_2 hydrocarbons, fraction 2, C_3 hydrocarbons, fractions 3 and 4, C_4 hydrocarbons, fractions 5–8, C_5 hydrocarbons, fractions 9 and 10, C_6 hydrocarbons (squalane, temperature, 40° C.)

sis can be hindered from occurring as a complex reaction of the original substance and the decomposition products being formed. It is necessary in order to achieve a satisfactory solution to have sufficiently extensive measurements of the chromatographic spectra of the various decomposition products and to use an instrumentation technique which allows working with microgram quantities of substances.

Our experiments were made with a high-temperature chromatograph manufactured by the firm (National Plant) Laboratory Instruments, Prague, which is equipped with a flame ionization detector, circulation air thermostat operating up to 350° C., and a recorder with a range of 0·2 mV. Squalane (30 per cent w/w on 'Celite 545') was used as stationary phase, nitrogen as carrier gas, and hydrogen served to maintain the flame. The substance was put on to the column in a quantity up to 0·1 mgm. directly or from an ethereal solution, on a platinum wire of 0·1 mm. in diameter, shaped in spiral form, 15 mm. in length and 1·5 mm. in diameter. By means of an electric time-switch reproducible heating of the platinum wire (up to 800° C.) for a precisely adjusted time (0·1–5·0 sec.) can be attained.

Experiments made with various plant oils and animal fats showed a surprising reproducibility of the chromatographic spectrum quality as well as a quantitative representation of the components, even with relatively large variations of the platinum wire temperatures and the heating time. This situation occurs—and this must be emphasized—only on using minute quantities of substances, 10–50 µgm., when an instantaneous removal of the pyrolytic products from the decomposition area takes place. The pyrolysis of substances with relatively small molecules (for example, fats, steroids) tends to be an 'isothermal' action and the molecule fragments are the result of the power balance within the molecule at this decomposition point and the equilibrium of radicals produced. In the case of pyrolysis of macromolecules such as rubber, etc., the qualitative reproducibility of chromatographic spectrum remains similar, but the quantitative composition is not so consistent.

Fig. 1 shows the pyrolytic spectrum of the C_1–C_6 hydrocarbon products which are formed by the pyrolysis of olive, hydrogenated olive and coconut oils. An obvious qualitative and quantitative shifting of the components in the chromatograms with a change of the chemical nature of the oil is apparent. Other oils, such as linseed oil or castor oil, also exhibit qualitatively and quantitatively specific pyrolytic spectra.

In order to clarify the relation between the composition of the decomposition products and the structure of the original substance, the pyrolysis products of a series of simple structurally related barbituric acid derivatives were studied. In Fig. 2 the chromatograms of three of the fourteen barbiturates studied can be seen. Fragments of the molecules present are always qualitatively as well as quantitatively highly specific. Not only can the group type of a soporific be differentiated, but also its

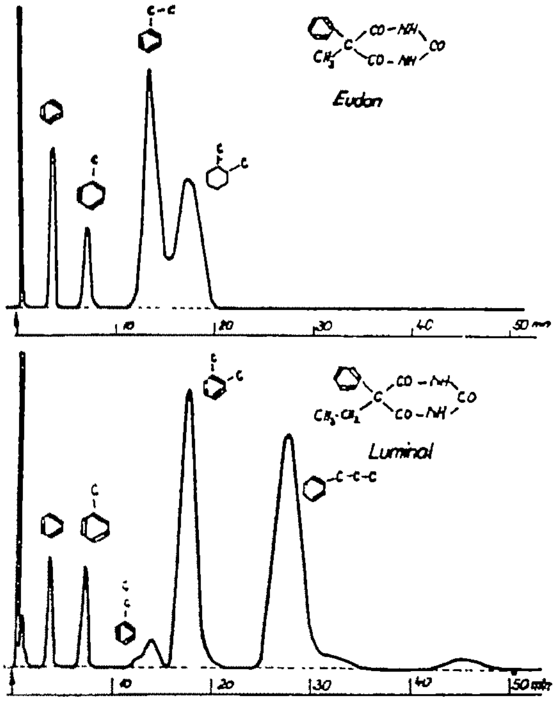

Fig. 3. Chromatogram of the pyrolytic products of the sodium salts of barbituric acid phenyl derivatives in the area of aromatic hydrocarbon fragments (squalane, temperature, 100° C.)

structure can be exactly determined. Experiments made *in vivo* supported the opinion that it would be possible to prove the structure of a barbiturate, after being taken, not only in the stomach content but also in the urine.

The pyrolytic procedure gives not only primary decomposition products. In the decomposition process radicals are formed which react in a characteristic way and form new components indicative of the structure of the original radicals. In Fig. 3 a spectrum of fragments in a range higher than benzene can be seen which shows components that are formed necessarily by the recombination of radicals.

A further improvement permits the use of various chromatographic column fillings for a double or multiple proof of the structure of the pyrolytic substances, the choice of various carrier gases for inducing structural changes in the decomposition products being formed and a temperature change of the chromatographic column (Figs. 2 and 3) for the exposure of a suitable part of the chromatographic spectrum.

This technique, particularly the gas chromatography, has considerably extended analytical potentialities in the field of the poorly volatile and non-volatile substances and is applicable to oils, alkaloids, steroids and other similar natural substances, artificial dyestuffs, drugs and other synthetic materials. Further, it serves as a basis for the development of rapid inquiry methods for medicinal and forensic chemistry, toxicology, biochemistry and biology, and is obviously useful in proving and verifying the structure of chemical individuals. Studies outlined in this communication will be published elsewhere in detail.

BIOCHEMISTRY

Effects of the Method of Tissue Preparation on the Assay of Tissue Enzyme Activities

THERE has recently been considerable interest in comparative enzyme-levels of various tissues of different species in health and disease. It is evident that the quantitative determination of enzyme activity in tissues is dependent not only upon the method used for measuring the activity, but also upon the method used for preparation of the tissue for analysis. Various factors, such as the intracellular localization of the enzyme, the availability of coenzymes and activators, and the permeability of both cellular and particulate membranes of different tissues to various substrate and product molecules, play a part in the effect of the preparation of the tissue prior to enzyme assay.

As a general principle, the method of choice for the preparation of tissue should be that by which maximum enzyme activity is obtained, that is, the method of preparation should not cause appreciable loss of enzyme activity, and should remove all membranes limiting the rate of the enzyme reaction. The assay medium should have optimal composition and contain any known coenzymes and activators of the enzyme studied. If careful consideration is not given to these matters significant discrepancies may appear in the work of a single laboratory or in the comparison of results obtained by different investigators.

In the course of some recent studies on the activity of alkaline phosphatase in the kidney of a patient with hypophosphatasia[1], a considerable discrepancy was noted between the results obtained using frozen-dried 16μ sections[2] and those obtained with aqueous extracts of tissue minces[3-5]. In order to investigate the cause of the discrepancy, alkaline phosphatase activity was determined by Lowry's method[6] in rabbit kidney cortex and liver tissue prepared for analysis by various methods. Also determined was lactic dehydrogenase activity by means of a fluorometric method[7].

Five methods of sample preparation were used: frozen-dried sections, crushed frozen-dried tissue, homogenate, frozen-dried homogenate, and minced tissue. The homogenate technique was included because it is the most widely used method of tissue preparation for enzyme assays. The crushed frozen-dried tissue method and the frozen-dried homogenate technique were included because they offer the possibility of long-term storage of the preparations. To obtain frozen-dried sections the tissue was frozen in liquid nitrogen and sections 16μ thick were cut at −20° C. The sections were then frozen-dried, weighed, and placed directly in the substrate medium. For the crushed frozen-dried tissue, the tissue frozen in liquid nitrogen was crushed in a pre-cooled stainless steel mortar by a blow of a hammer on the pestle. Part of the powder was inserted into a previously weighed cold 13 mm. × 100 mm. 'Pyrex' tube, weighed, and lyophilized. The tube was then stoppered and stored at − 35° C. until used. Prior to analysis, the powder was reconstituted with enough water to make it 5 per cent on a wet-weight basis. For the homogenate a 5 per cent aqueous homogenate was made in a Potter–Elvehjem tissue grinder using a Kontes Glass Co. stainless steel pestle (clearance 0·009–0·011 in.) and then a Kel-*F* pestle (clearance 0·004–0·006 in.). The homogenization was continued long enough to pass all the tissue up and down a few times. To obtain frozen-dried homogenate, 1 ml. aliquots of the homogenate were shell frozen in 13 mm. × 100 mm. 'Pyrex' tubes and lyophilized. The tubes were stoppered and stored at − 35° C. until used. The powder was reconstituted with 1 ml. water prior to analysis. In the case of the mince, the tissue was finely minced with scissors and suspended in enough water to make it 5 per cent on a wet-weight basis. The suspension was covered with toluene and stored at 4° C.

The results are summarized in Table 1, upper part. Frozen-dried tissue sections showed both alkaline phosphatase activity and lactic dehydrogenase activity 2–8 times greater than any other preparation. The enzyme activity of frozen-dried homogenate in most instances showed somewhat greater activity than crushed frozen-dried tissue, homogenate or minced tissue. Homogenate and minced tissue stored

* 0·1 *M* phosphate buffer, *p*H 7·4, containing 0·05 per cent bovine serum albumin.

All activities based on dry weight; activities in upper part of table expressed in percentage of the activity of a frozen-dried section of the same tissue, in lower part in percentage of the activity of the fresh homogenate in water. Standard errors of the means shown with number of samples in parentheses.

for 7–8 days showed slightly greater alkaline phosphatase activity and slightly lower lactic dehydrogenase activity than homogenate and minced tissue stored for only one day. In the case of alkaline phosphatase, a very stable enzyme, the rate of solubilization of the enzyme into the extracting fluid is apparently higher than the rate of denaturation, while in the case of lactic dehydrogenase, a less stable enzyme, the rate of denaturation is apparently faster than the rate of solubilization. The high results obtained with frozen-dried sections can probably be explained by the rapid and complete rupture of cell membranes which occurs when the section is put into contact with aqueous substrate. Microscopically this process has been observed as a very rapid swelling and soaking of the dry tissue at the moment of immersion.

In another experiment homogenization was carried out in 0·1 *M* phosphate buffer (*p*H 7·4), containing 0·05 per cent bovine serum albumin, instead of in water. In the same experiment fresh homogenates were compared with those kept at − 35° C. for one day. The results are given in Table 1, lower part. No increase in the activity of either enzyme was noticed by replacing water with the phosphate–albumin medium. In the case of alkaline phosphatase a slight inhibition occurred, probably due to a mass law effect. No significant differences existed between the fresh homogenates and the homogenate which had been frozen and kept at − 35° C. for one day.

It appears that the highest results for both enzymes were found in the frozen-dried sections, while the frozen-dried homogenate method seems to be the next best technique. It is probable that differences in enzyme activity, depending on the method of preparation of tissues for analysis, will also be found for other enzymes. It appears evident that certain discrepancies in comparative tissue enzyme studies can be avoided if cognizance is taken of the critical importance of the methods of preparation of tissues for enzyme assay and the need for careful standardization in each study.

Formation of Carotene *in vitro*

RESULTS presented in this communication indicate that both β-hydroxy β-methylglutarate and mevalonate may be considered precursors of carotene formation in an *in vitro* extract obtained from mycelial mats of the mould *Phycomyces blakesleeanus*. This extract, capable of synthesizing carotene, can also be used for establishing the existence of a back reaction from the mevalonate to β-hydroxy β-methylglutarate, for brevity referred to as glutarate.

The sequence of conversions is, however, undoubtedly similar to those previously proposed for carotenoids[1–4] and sterols[5]. In the initial stages of the formation of isoprenoid compounds, at least, there is an identity in the 5 and 6 carbon intermediates.

Previous work has shown that glutarate and mevalonate are used with considerable efficiency in the synthesis of carotenoids in tomatoes, tomato and carrot homogenates, and by growing cultures of *Phycomyces*[1–4]. Goodwin has reviewed evidence that glutarate is a direct precursor of mevalonate in plant systems[4]. However, the experimental conditions in growing plants were such that enzymatic breakdown to acetate could occur, and thus mevalonate might arise independently.

In a series of tests, a cell-free extract has been obtained from mycelial mats of *Phycomyces* which is capable of synthesizing labelled carotene from acetate 2-^{14}C, glutarate 3-^{14}C and mevalonate 2-^{14}C.

The soluble system was isolated from five-day old cultures of *Phycomyces* grown on a medium containing 2·5 per cent glucose, 0·125 per cent leucine, 0·125 per cent asparagine, with added salts and thiamine. The extract was prepared by disintegrating the mycelial mats (about 100 gm. fresh weight) in a loose-fitting tissue homogenizer, at *p*H 7·8 in 0·2 *M tris*-hydrochloric acid buffer which contained in addition nicotinamide, versene, and glutathione, all 0·002 *M*. The homogenate was centrifuged at 4,000*g* for 10 min. to remove gross particles, after which the supernatant was decanted. This was dialysed against 0·002 *M* *tris*-hydrochloric acid buffer for 12 hr. All manipulations were carried out at 4° C. The dialysed material contained 11 mgm. of protein per ml. In an experiment, 4 ml. aliquots were placed in flasks, containing 10 μM of adenosine triphosphate, 1 μM each of diphosphopyridine nucleotide, triphosphopyridine nucleotide and reduced diphosphopyridine nucleotide and 10 μM magnesium sulphate. Substrates in the amount of 5 μM per 4 ml. were added, and the mixture was then incubated for 18–30 hr. at room temperature.

A protein pellet containing the carotene was obtained by centrifuging the test mixture at 10,000*g*. The β-carotene was extracted from the pellet, chromatographed, and the carotene was crystallized with the aid of carrier, washed with hot absolute alcohol and dried as previously described[6]. The carotene was then dissolved in toluene and bleached under a light source rich in ultra-violet for 8 hr. in capped vials. After bleaching, scintillation phosphors ('PPO' and 'popo') were added by injection through the rubber cap of the vial and the resultant solution counted in a Packard 'Tricarb' scintillation counter.

The interconversion of substrates in the supernatant was established as follows. The solution was passed over a 'Dowex 50' column and afterwards over one of 'Dowex 1', on which the free organic acids were absorbed. They were eluted, re-passed over 'Dowex 50', and thus isolated. Phosphorylated derivatives are apparently lost by this procedure, and only the free acids were obtained. The solution was then concentrated and portions were chromatographed on Whatman No. 1 paper, by use of ethanol–ammonia–water (80 : 5 : 15), solvent 1, and *n*-butanol–acetic acid–water (4 : 1 : 5), solvent 2. The paper was then sprayed with bromphenol blue. The activity of the spots was determined by removing strips of the paper containing the visualized spots and counting in sections in a windowless flow counter.

Table 1 lists the total counts added in the different substrates used, and the resultant activities found in the β-carotene. The activity of the substrates was determined by scintillation counting and the counts were adjusted against an internal counting standard to place results on a comparable basis.

For mevalonate, between 1 and 4 per cent of the activity was incorporated into the carotene; for glutarate, about 0·7 per cent; for acetate 2-^{14}C, only a trace. These figures represent lower limits for recovery of activity since the carotene was crystallized.

Table 2 lists the activity of the organic acids isolated from the supernatants. Acetate gives rise to both mevalonate and glutarate, and these are interconvertible. No significance can be attached to the ratios of glutarate : mevalonate activity as there is no information as to the extent to which glutarate may have been diverted into other paths. In addition to well-defined spots for glutarate and mevalonate with R_F values (inadvertently reversed in our earlier paper[4]) of 0·65, 0·59, respectively, for solvent 1, and 0·80, 0·78 for solvent 2, there was an unknown substance showing considerable activity with R_F values of 0·39 and 0·76 in the two solvents.

Table 1. INCORPORATION OF ACTIVITY INTO β-CAROTENE

Substrate	Total c.p.m. added	Total c.p.m. in carotene
Acetate 2-^{14}C	1,100,000	265
Mevalonate 2-^{14}C	170,000	6,997
Mevalonate 2-^{14}C	370,000	3,724
Glutarate 3-^{14}C	187,000	1,296

Table 2. INTERCONVERSION OF ORGANIC ACIDS

Organic acids substrate added	Total c.p.m. found	
	Mevalonate	Glutarate
Acetate 2-^{14}C	202	1,226
Mevalonate 2-^{14}C	(18,170)	4,140
Glutarate 3-^{14}C	2,096	(2,392)

The net increase in carotene in these experiments is usually of the order of 5–10 μgm. The mildest treatment in the homogenizer with removal of unbroken cells by centrifugation seems the most promising lead to improvement of yield.

The foregoing results indicate that both glutarate and mevalonate may be considered as precursors of carotenoids in the system studied, and the evidence substantiates existence of a back reaction from mevalonate to the (hydroxy- methyl-) glutarate.

Influence of Sorbic Acid on Acetate Oxidation by *Saccharomyces cerevisiae* var. *ellipsoideus*

SORBIC acid (2,4-hexadienoic acid) is widely used as a food preservative. Its effective action against different micro-organisms[1–5] and its harmlessness as a dietary component[6], as well as the ease of its quantitative determination[7–8], and its chemical stability[9] are among the main reasons for its rapid adoption in the food industry.

Sorbic acid has a selective action against catalase-positive organisms[10], and its use as a component of enrichment media for species of *Clostridium* has been proposed[11]. Although the mechanism of its inhibitory action is not well understood, it has been suggested that it probably interferes with the activity of the dehydrogenases in the cell[12].

In the experiments to be described in this communication, we have used a strain of *Saccharomyces cerevisiae* var. *ellipsoideus* which was isolated from fermenting grape juice. The cells were grown on autolysed yeast–dextrose agar. After incubation for some 15 hr. at 30° C., they were harvested and washed twice with 0·033 *M* monopotassium phosphate solution, and finally resuspended in the same solution to an optical density corresponding to a concentration of 2·0 mgm. dry matter per ml. 2 ml. of this suspension were used for each Warburg

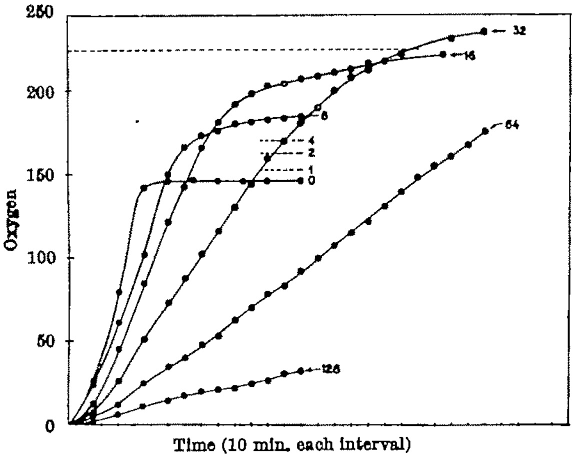

Fig. 1. 4 0 mgm. (dry weight) of cells in each Warburg vessel. Potassium hydroxide in the central cup. 5 μmol. of acetate in all cases. The total amount of sorbate (in μmol.) is indicated at the end of each curve. The upper dotted line represents the theoretical amount of oxygen required for complete oxidation of acetate

vessel, and the oxygen uptake was measured at 30° C. with the conventional technique. Our first experiments showed that there was a small but definite increase of the oxygen uptake over the endogenous by cells in the presence of this compound. This effect was found to be due to an impurity which could be removed by recrystallization from water.

Fig. 1 shows the effect of different concentrations of sorbic acid (added as the sodium salt) on the oxidation of acetate by our strain. The compound has an influence on both the respiration-rate and on the total oxygen uptake by the cells. In the cases where 1, 2 and 4 μmol. of sorbate had been used, only the final values are indicated in the graph. Carbon dioxide determinations by the indirect method showed a respiratory quotient of 1 in all cases.

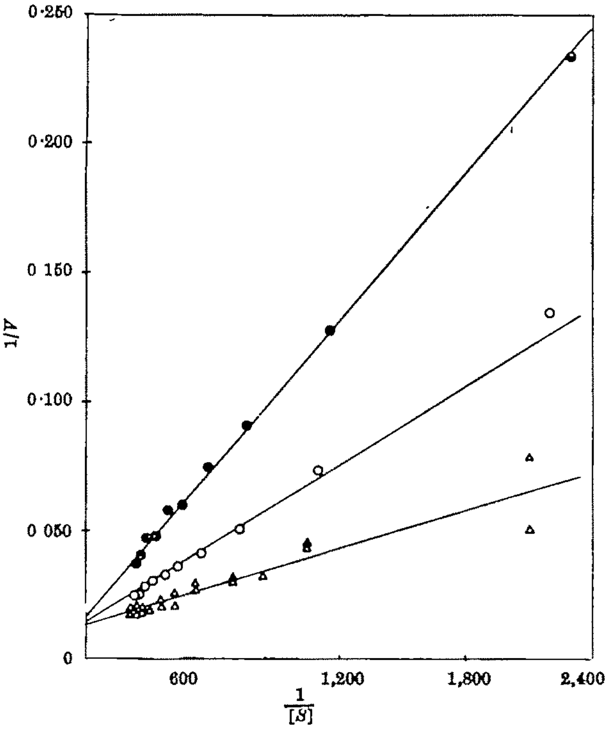

Fig. 2. 4 0 mgm. (dry weight) of cells in each Warburg vessel. Potassium hydroxide in the central cup. The concentration of acetate was varied from 1 to 10 μmol. The straight part of each curve was used for calculating the velocities of respiration. △, No inhibitor; ○, 16 μmol. sodium sorbate; ●, 32 μmol. sodium sorbate

The inhibitory effect of sorbate on the respiration-rate is competitive, as shown by a 'double reciprocal' plot (Fig. 2). Although the exact mechanism of the competition has not been determined, some preliminary experiments seem to indicate that sorbate interferes with the synthesis of citric acid in the cells, probably by way of formation of sorbyl–coenzyme *A*. Sorbic acid also inhibits the acetylation of sulphanilamide by pigeon liver extracts.

The inhibition of acetate assimilation is more difficult to explain. There was no appreciable effect of sorbate on the oxidative phosphorylation by whole cells in the presence of acetate and the inhibitor. Since our manometric experiments were performed under conditions (absence of carbon dioxide in the atmosphere and of combined nitrogen in the medium) which rule out any significant assimilation through the Krebs cycle, it is possible that sorbate could interact with the synthesis of higher fatty acids by the resting cells.

Low Molecular Weight Organic Base from the Dinoflagellate *Amphidinium carteri*

In the course of an investigation into the nature of the soluble carbohydrate materials released by phytoplankton into their culture medium[1], we found that media from cultures of *Amphidinium carteri*, a dinoflagellate, showed a distinctly blue reaction with N-ethyl carbazole, rather than the usual purple-red colour. The material causing the blue reaction could be removed by dialysis, which also removed the fishy odour characteristic of old cultures of this organism. The dialysate displayed the usual carbohydrate colour reaction.

The substance responsible for the blue reaction, and presumably also for the fishy odour, is very labile. The product originally released into the medium by this organism is somewhat more complex than the dialysable substance responsible for the blue reaction, since samples of filtered medium taken from bacteria-free cultures in the logarithmic stage of growth do not develop the characteristic odour for several hours. The autohydrolysis of the parent compound can be prevented by making the medium slightly acid after filtration, and storing the material at low temperature.

The process of autohydrolysis can be followed by applying the cupric chloride test for aliphatic amines described by Hershenson and Hume[2]. If cold, slightly acid medium is tested, no immediate reaction is visible. After several hours at room temperature a definite positive colour reaction develops. If the parent substance is hydrolysed by refluxing with dilute sodium hydroxide, the test shows an immediate positive reaction.

The dinoflagellate cells contain a substance, probably an enzyme, which can hydrolyse the parent compound very quickly. If cells are damaged in the course of filtration, the fishy odour develops immediately. This hydrolysis can be prevented by the addition to the medium of eserine, an anticholinesterase. The end-product, however, displays none of the chemical reactions of choline. The original product may be an analogue of acetylcholine, since both acetylcholine and acetyl-β-methylcholine behave in the same manner as does the original product in the amine and N-ethyl carbazole tests.

It seems probable that *Amphidinium carteri* releases some analogue of acetylcholine either as a waste product or as a protective device. Such a compound should be physiologically active, and might act as effective protection against zooplankton. The organism itself contains a mechanism for breaking down this compound. This compound or similar compounds may be released by other dinoflagellates. Abbott and Ballantine[3] extracted centrifuged cells of *Gymnodinium veneficum* with acidified methanol and removed a compound the effects of which on mice were similar to those of acetylcholine. An acidified methanol extract of an activated carbon column through which medium from the *Gymnodinium* culture had been passed gave similar results.

Enzymic Synthesis of L-Aspartate-4-^{14}C

As the use of radioactive isotopes in research has been extended, there has been an increasing demand for specifically labelled metabolites of high activity. At present the synthesis of such compounds by purely chemical means is often difficult, if not impossible, particularly when only the biologically active isomer is required. While enzymic synthesis is recognized to be desirable in principle, some workers may be deterred by the difficulties involved in preparing the required enzymes to what is considered to be the necessary state of purity.

What may be overlooked is that it is frequently possible to isolate an enzyme biochemically rather than physically by adding to an adequately dialysed mixture only that combination of substrates, coenzymes and co-factors which is necessary for its activation. In these circumstances it may prove possible, as in the present instance, to use crude (and therefore more easily prepared) enzymes to effect specific syntheses.

Previous work[1] has indicated that L-aspartate-4-^{14}C can be synthesized enzymically *in vitro* by combining the reactions catalysed by phosphopyruvate carboxylase[2] and glutamic–aspartic transaminase. The overall reaction is:

$$\begin{aligned}&CH_2:COPO(OH)_2{\cdot}COOH + {}^{14}CO_2 + H_2O + \\ &\qquad HOOC{\cdot}CH_2.CH_2{\cdot}CHNH_2{\cdot}COOH \rightarrow \\ &HOO^{14}C{\cdot}CH_2{\cdot}CHNH_2{\cdot}COOH + \\ &\qquad HOOC{\cdot}CH_2{\cdot}CH_2{\cdot}CO{\cdot}COOH + H_3PO_4 \end{aligned} \quad (1)$$

Recently, experiments have been undertaken in this laboratory in order to determine whether this accurately represents the reaction involved.

The enzymes required for the synthesis were prepared by grinding 100 gm. of *Kalanchoë crenata* leaves in 100 ml. of 0·625 per cent 2-amino-2-hydroxymethylpropane-1 : 3-diol (*tris*). The protein present in the clear supernatant after centrifugation at 20,000*g* was precipitated by making 100 per cent w/v with ammonium sulphate. The precipitate was redissolved in 30 ml. of 1 per cent *tris* buffer at *p*H 7·5 and dialysed against 3 l. of this solution in the cold for 48 hr. and then against 3 l. of mineral-free water for a further 24 hr.

The reaction was started by the addition of excess phosphoenolpyruvate (50 μmoles) to a stoppered vessel of 7 ml. capacity containing sodium bicarbonate (approximately 22 μmoles at 22·8 μc./μmole), enzyme (5·0 ml.), magnesium chloride (7 μmoles), glutamate (75 μmoles), sodium phosphate (7 μmoles) and *tris* buffer (0·10 ml., 20 per cent w/v at *p*H 7·4). After incubation for 1 hr. at room temperature the reaction was stopped by the addition of formic acid. The acidified reaction mixture was boiled to remove formic acid, and then passed through a column of acid alumina which absorbed all the residual radioactivity. Water was passed through the column until activity appeared in the effluent. Ammonia was then passed through the column until the major part of the activity had been recovered.

Two-dimensional chromatography of the ammonium hydroxide eluate followed by radioautography indicated that radioactivity was restricted to two spots. The first of these corresponded in position to that of added aspartate and contained more than 99 per cent of the activity. The second spot, containing less than 1 per cent of the activity, has not yet been identified but may be oxaloacetate.

When the radioactive eluate from the aspartate spot on two-dimensional chromatograms was incubated with indanetrione hydrate in 'Methyl cellosolve' at *p*H 5 the activity was lost, indicating that the label was restricted to the carboxyl groups[3]. Similarly, the activity was lost as labelled carbon dioxide when the eluate was incubated with an enzyme preparation from *Nocardia*. This enzyme has been shown[4] to catalyse, specifically, the quantitative β-decarboxylation of L-aspartate and this result therefore provides convincing evidence that the labelled substance is in fact L-aspartate-4-^{14}C.

A comparison of the radioactivity of the aspartate fraction and that of standard carbonate-^{14}C (measured with a Geiger–Müller counter under similar conditions) indicated that the level of activity in the aspartate was greater than 400 μc. The amount of aspartate synthesized was determined by spectrophotometric measurements of reduced diphosphopyridine nucleotide oxidized in the overall enzymic reaction:

$$\text{aspartate} + \alpha\text{-oxoglutarate} + \text{DPNH}_2 \longrightarrow \text{malate} + \text{DPN} + \text{glutamate}$$

and found to be approximately 20 μmoles. On the basis of this figure the specific activity of the aspartate was evidently close to that of the bicarbonate used in its synthesis.

These results clearly indicate that virtually all the carbon dioxide fixed is located in the β-carboxyl group of L-aspartate and are consistent with the view that equation 1 is an accurate representation of the reaction.

We wish to acknowledge a gift of *Nocardia* enzyme from Dr. Kerridge, M.R.C. Unit of Microbiology, University of Cambridge, and grants from the University of London Central Research Fund and the Department of Scientific and Industrial Research made to one of us (D. A. W.).

Decrease in Coenzyme I Content of Spleen after Freezing

During an investigation into the effect of the level of coenzyme I on the response of tissues to hydrocortisone, it was necessary to keep the tissues for at least a day before the coenzyme-level could be estimated. As a supply of solid carbon dioxide ('Drikold') was available it was used to freeze the tissues quickly before storing in a deep freeze.

Table 1. Comparison of Diphosphopyridine Nucleotide (DPN$^+$) Content of Freshly Killed and Frozen Rat Tissues

Tissue	γ-DPN$^+$/gm. fresh weight ± *S.E.*				Percentage decrease in DPN$^+$ caused by freezing
	Freshly killed	No. of estimations	Frozen	No. of estimations	
Diaphragm	256 ± 13·25	4	250 ± 7·14	4	—
Kidney	275 ± 8·75	5	277 ± 11·84	4	—
Liver	236 ± 8·43	8	194 ± 6·12	7	18
Blood*	44·2 ± 2·35	5	36·3 ± 2·16	5	18
Spleen	129 ± 5·19	10	16·8 ± 1·41	12	87

* Blood results expressed as γ-DPN$^+$/ml. whole blood.

The method of extracting the oxidized coenzyme I was that of Glock and McLean[1], except that sodium carbonate was used for neutralizing the acid. The diphosphopyridine nucleotide was then estimated by the fluorescence method[2]. Approximately 100 mgm. of tissue was used for each estimation. Rat tissues investigated were diaphragm, kidney, liver and spleen. It was found that freezing as soon as the tissue was removed from the animal had little or no effect on the content of diphosphopyridine nucleotide except in the case of spleen. As spleen contains a high proportion of blood, this tissue was also investigated (Table 1).

Spleens from two other species—rabbit and guinea pig—were similarly treated and the same type of result obtained from frozen and unfrozen tissue (Table 2). Other available freezing agents—liquid oxygen and alcohol/solid carbon dioxide mixture—were used with rat spleen. Values of 17·8 and 34·0 γ-diphosphopyridine nucleotide per gm. of tissue were obtained respectively.

The buffer method for extracting coenzyme I from tissues of Jedeikin and Weinhouse[3] was tried with rat spleen and the fluorescence method used for the estimation. The average value for unfrozen tissue was higher than that obtained from the other extraction technique due to lower fluorescent blanks. Again, frozen tissues gave low results, the percentage of lowering being similar to that previously obtained (Table 2). When the complete method of Jedeikin and Weinhouse was used with large amounts of rat spleen (600 mgm.), diphosphopyridine nucleotide in extracts from frozen tissue was too small to measure accurately (Table 2).

Thawing frozen tissue before adding to the hot extracting fluid did not increase the value of coenzyme estimated above that of unthawed tissue. Length of freezing did not appear to affect the low results. Tissue which had been quickly frozen and estimated immediately gave results similar to tissues that had been stored frozen for some time. Freezing the neutralized extract from unfrozen spleen in solid carbon dioxide before fluorescence estimation did not lower the coenzyme content.

At first an inhibitor of the fluorescence was thought to be present. The blank obtained from frozen tissues was only 37 per cent of that from unfrozen tissues of the same weight, but known amounts of oxidized diphosphopyridine nucleotide (Sigma grade) added to the extracts or to the extracting acid at the same time as the tissues gave similar recoveries from both fresh and frozen tissues.

It was noticed that the colour of the neutralized extract from frozen tissue was a much darker brown than that from unfrozen tissue. Chromatography,

Table 2. Diphosphopyridine Nucleotide (DPN$^+$) Content of Fresh and Frozen Spleen Tissue from Different Species

Animal	Method of extraction*	Method of estimation*	γ-DPN$^+$/gm. fresh weight ± *S.E.*				Percentage decrease in DPN$^+$ caused by freezing
			Fresh	No. of estimations	Frozen	No. of estimations	
Rabbit	1	2	156	2	12·6 ± 1·26	3	92
Guinea pig	1	2	112 ± 3·13	3	13·6 ± 1·18	3	88
Rat	1	2	129 ± 5·19	10	16·8 ± 1·41	12	87
Rat	3	2	159 ± 4·37	6	20·4 ± 1·39	4	87
Rat	3	3	119	2	—	2	—

* Figures relate to references as given in the text.

using pyridine/water as solvent[4], of these extracts after concentration by freeze drying showed larger brown non-fluorescent streaks in samples from frozen tissue than from fresh tissue, but no clearly defined diphosphopyridine nucleotide spot was detected.

The loss of coenzyme I content on freezing would not appear to be due to enzyme activity as the time for any breakdown is too short and the temperature too low. It also does not appear to be a simple inhibition in the fluorescence estimation. Thus apparently during freezing some physico-chemical phenomenon takes place.

ANIMAL PHYSIOLOGY

Water Content of Cod (*Gadus callarias* L.) Muscle

In fatty fish such as herring the protein content of the flesh does not show any regular cycle of changes throughout the year[1,2]. Marked variation is shown by the fat, however, which decreases in times of food scarcity, the flesh showing a corresponding increase in water content. Non-fatty fish such as cod do not behave in this way, and in times of scarcity they draw on their body proteins both for metabolic purposes and for building up the gonads[3]. Water then takes the place of the protein, and in the case of cod artificially starved to the point of death it can increase to as much as 88 per cent of the flesh as compared with about 80·5 per cent in normal fish[4].

Although many determinations of the water content of fish muscle have been carried out, the rather small variations encountered in non-fatty fish landed at commercial ports have rarely been commented on. The following results show, however, that considerable biological information can be obtained from them.

The cod analysed were all obtained from the same ground, about 30 miles south-east of Aberdeen. They were filleted within 12 hr. of being caught, and myotomes 8–16, approximately (counting from the anterior end of the fillet) were dissected out free from myocommata (connective tissue) and placed in weighed basins, approximately equal weights of material being taken from each fish in a sample. Water was determined by drying in an oven at 100° C. for seven days.

Three size-groups of fish were used: (1) 20 in. long or less (sexually immature); (2) close to 30 in. long (about the size when they become mature); (3) 36–42 in. long (mature). It was difficult to get fish in the latter group at certain times of the year, and each sample consisted of pooled material from only 1–8 such fish. Material from medium-sized fish was obtained from 10 individuals, while 20 individuals were used for the 'small' group.

The results (Fig. 1) show that the water content is affected by the size of the fish as well as by the season, the maximum in March corresponding with the period of spawning. Not only is tissue hydration greater in larger fish than in smaller, but in addition it lasts longer (about 3 months). The smallest fish are affected for just one month, recovering in April, and it is likely that this effect is due solely to starvation, since the fish are immature. The findings are in accordance with previous observations[3], which showed that the reduction in protein nitrogen was greater in larger fish than in small, owing to the additional need of larger fish to build up gonads on a food supply inadequate even for ordinary metabolism.

There is little doubt that the height of the maximum in Fig. 1, and also its location, depends on the place where the fish were caught, and probably on the year of catching as well. The highest water content that we ever found under natural conditions (87·2 per cent) was in a cod 42 in. long caught off the west coast of Scotland at the beginning of June 1959. The maximum in Fig. 1 is in March 1959, so this isolated observation provides an example of the effect of a different fishing ground.

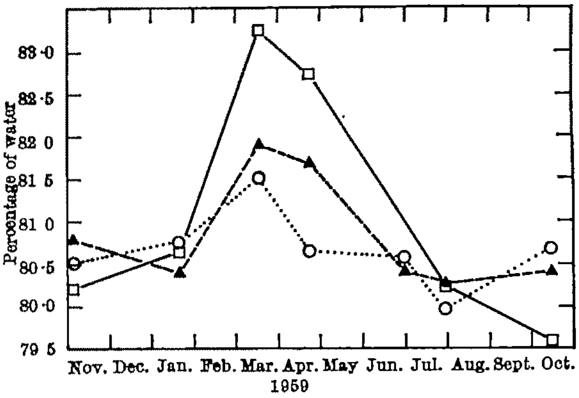

Fig. 1. The water content of cod muscle tissue at different times of the year. ○ · · ○, Small fish; ▲ - - - ▲, medium fish; □ —— □, large fish. Large fish were not obtainable in June

In a recent review of fish composition[5] it was recommended that in order to obtain the complete picture of the variations in a given constituent, analyses should be carried out at monthly intervals for a year on fish of at least two age groups, the fishing ground being the same throughout. From the data in Fig. 1, the recommendation would not appear to have been unreasonable.

The work described in this communication is part of the programme of the Department of Scientific and Industrial Research.

Turnover of the Copper and Protein Moieties of Ceruloplasmin

APPROXIMATELY 95 per cent of the plasma copper in both mouse and man is normally present as a moiety of ceruloplasmin[1]. Ceruloplasmin, an α-globulin containing 0·34 per cent copper, exhibits oxidase activity *in vitro* with a variety of substrates[2] and reversibly releases at least half its copper upon reduction[3]. Whether ceruloplasmin plays a part in the transport of copper or acts as an oxidase *in vivo*, however, is not known. In the work reported here, the function of ceruloplasmin in mice was investigated by determining the rate of exchange of its copper moiety.

Human ceruloplasmin isolated from pooled plasma[3] was kindly supplied by Dr. I. H. Scheinberg. The protein moiety of an aliquot of the preparation was labelled with iodine-131 at *p*H 6·8 using the nitrite method described elsewhere[4]. Iodination did not alter the reactivity of the ceruloplasmin with specific rabbit antisera[5] or change its visible spectrum. More than 98 per cent of the radioactivity of the preparation was precipitable in 10 per cent trichloracetic acid. The iodoceruloplasmin was finally screened in Swiss albino mice for 24 hr. to remove any denatured labelled protein, as suggested by McFarlane[6].

Additional aliquots of human ceruloplasmin were labelled with copper-64 using an exchange method[3]. Of the total radioactivity in these preparations, 92–95 per cent was precipitable with rabbit antiserum.

Labelled mouse ceruloplasmin was obtained by injecting mice intraperitoneally with 100 μgm. copper containing 300 μc. copper-64. Serum collected 24 hr. later had a final activity of 1·7 μc. per ml., of which almost 98 per cent was associated with ceruloplasmin electrophoretically. The pooled serum was used as the preparation of mouse ceruloplasmin in these experiments.

Groups of Swiss albino mice 6–7 weeks old were given 0·5 μc. of one of the labelled ceruloplasmins intravenously; this was equivalent to 20 μgm. human ceruloplasmin labelled with iodine-131, 200 μgm. human ceruloplasmin labelled with copper-64, or 40 μgm. mouse ceruloplasmin labelled with copper-64. The mice were assayed in a well-type sodium iodide crystal scintillator. Three or four mice from each group were killed at intervals; serum and various organs were assayed for radioactivity.

The half-life of iodine-labelled human ceruloplasmin, $t_{i\frac{1}{2}}$, as determined by its disappearance from the total body or from serum (Fig. 1), was 0·92 day. The copper-64 in human and mouse ceruloplasmins disappeared from serum with half-lives, $t_{h\frac{1}{2}}$ and $t_{m\frac{1}{2}}$, of 0·75 and 0·85 days, respectively. With human ceruloplasmin at least, copper-64 disappeared more rapidly than the protein moiety was degraded, suggesting a slow exchange of ceruloplasmin copper in the serum; the half-life of this exchange, $t_{\frac{1}{2}}$, was calculated:

$$t_{\frac{1}{2}} = \frac{t_{i\frac{1}{2}} \cdot t_{h\frac{1}{2}}}{t_{i\frac{1}{2}} - t_{h\frac{1}{2}}} = 4{\cdot}1 \text{ days}$$

From 2 hr. following the injection of labelled human ceruloplasmin to the end of the experiment, less than 1 per cent of the serum radioiodide and less than 2 per cent of the serum radiocopper were not precipitable with rabbit antiserum versus human ceruloplasmin[5].

It can be seen from Fig. 1 that the amount of ceruloplasmin in the total body after distribution of the protein in the body fluids was approximately twice the amount present in the serum. Since the average serum ceruloplasmin concentration in these mice was 13 mgm. per 100 ml. serum and the plasma volume was 1·14 ml., the total ceruloplasmin pool was 0·3 mgm. containing 1·0 μgm. copper. With a half-life of 4·1 days, the amount of copper exchanged within the ceruloplasmin pool per day was 0·17 μgm. The mice studied here ingested 45–75 μgm. copper a day in the diet they received; of this, tracer studies with copper-64 indicated that they absorbed a minimum of 4·5–7·5 μgm. copper a day[7]. It is clear that the amount of ceruloplasmin copper exchanged per day was less than 4 per cent of the amount of copper absorbed from the intestinal tract. This would appear to militate against the suggestion that absorption of copper from the intestines is inhibited or controlled by extensive dissociation of ceruloplasmin copper in the intestinal plasma[3]. The small exchange of ceruloplasmin copper would also indicate that ceruloplasmin does not function to transport copper from the intestines unless the intestines synthesize ceruloplasmin. But even the synthesis of ceruloplasmin by one tissue with subsequent release of its copper in other tissues through degradation could result in the transport of only 1·5 μgm. copper per day.

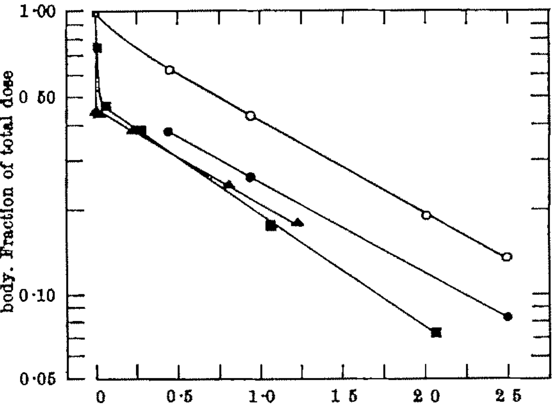

Fig. 1. The disappearance of labelled ceruloplasmins after intravenous injection in mice. From total body: human ceruloplasmin labelled with iodine-131 (○). From plasma: human ceruloplasmin labelled with iodine-131 (●); human ceruloplasmin labelled with copper-64 (■); mouse ceruloplasmin labelled with copper-64 (▲)

On the other hand, the observed exchange in ceruloplasmin copper, although quite small, suggests that ceruloplasmin may act, at least in part, as an oxidase *in vivo*.

Effect of Adrenaline and Insulin upon the Oxygen Consumption of Hyperthyroid Rats

It has long been known that the administration of thyroxine to rats, or any other species, is followed by an increase in their basal metabolic rate. In the present experiments rats fed thyroid were found to respond to the injection of adrenaline by a further marked and sustained rise in oxygen consumption. No such increase could be demonstrated in normal control animals. This increased sensitivity of hyperthyroid rats to adrenaline, as reflected in their oxygen consumption, was used to examine the release of adrenaline in insulin hypoglycæmia.

Male and female black-hooded rats (average weight 167 gm.) were used. The addition of thyroxine to their drinking water (0·125 mgm./100 ml.) for seven days before the experiment resulted in a 40 per cent increase in oxygen consumption (from 25 to 35 ml./5 min.). The rats were given no food and only limited water for 18 hr. prior to the experiment. The apparatus used was a modification of the spirometer described by Holtkamp *et al.*[1]; this permitted the oxygen consumption of individual rats to be recorded separately. The rats were allowed to become accustomed to the apparatus for 40–60 min. and thereafter their resting oxygen consumption was determined over a period of 1 hr. The animals were then removed, injected and immediately returned to the spirometer. Following this disturbance there was a transient rise in oxygen consumption; but control experiments in which saline was injected (4 rats, Fig. 1) showed that this was insignificant when compared with the increases following the injection of adrenaline or insulin.

The subcutaneous injection of 50 μgm. of DL-adrenaline into four rats fed thyroid was followed by a considerable rise in the consumption of oxygen (Fig. 1). In four normal rats, the change in oxygen consumption after the injection of the same quantity of adrenaline was insignificant.

The injection of insulin (0·125 unit) subcutaneously into six hyperthyroid rats caused a conspicuous increase in the consumption of oxygen (Fig 2). No such increase could be demonstrated in four normal animals given the same dose of insulin. This rise in oxygen consumption produced by insulin in rats fed thyroid was prevented by the simultaneous intraperitoneal injection of 1·5 ml. of a 30 per cent solution of glucose into a series of eight similar animals (Fig. 2). Any animal that developed hypoglycæmic convulsions was excluded from the series of experiments.

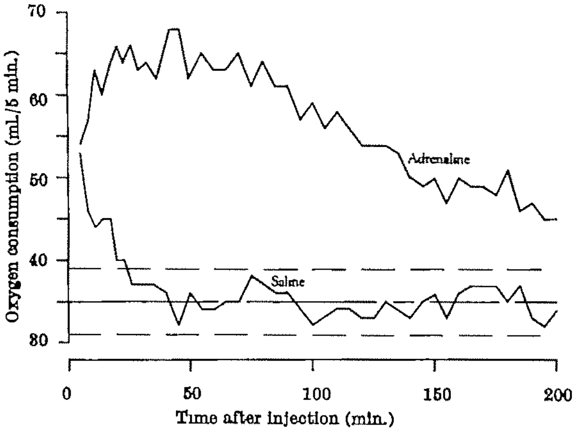

Fig. 1. Effect of adrenaline upon the oxygen consumption of hyperthyroid rats. Upper curve, effect of 50 μgm. of DL-adrenaline in 0 1 ml. saline. Mean of four experiments. Lower curve, effect of the injection of 0·1 ml. saline. Mean of four experiments. The broken lines are drawn two standard deviations from the mean of the resting oxygen consumption

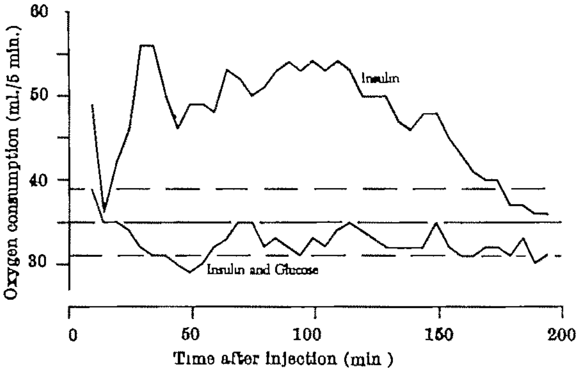

Fig. 2 Effect of insulin upon the oxygen consumption of hyperthyroid rats. Upper curve, effect of 0·125 unit of insulin (subcutaneous injection) and 1 5 ml. saline (intraperitoneal injection). Mean of six experiments. Lower curve, effect of insulin (0·125 unit subcutaneously) and of glucose (1 5 ml., 30 per cent solution intraperitoneally). Mean of eight experiments. The broken lines are drawn two standard deviations from the mean of the resting oxygen consumption

It has been shown[2] that the increased oxygen consumption in the hyperthyroid state could be reduced to normal levels by a total sympathetic block and thereafter restored to the original level by infusion of adrenaline or noradrenaline. As large doses of adrenaline are required to produce even a transient rise in oxygen consumption in normal animals, it was suggested that hyperthyroid animals were unduly sensitive to the calorigenic effects of adrenaline. The sustained and pronounced increase in oxygen consumption following injection of adrenaline into hyperthyroid rats and the insignificant increase produced by the same dose of adrenaline in normal animals, shown in the present experiments, would accord with this suggestion.

The rise in oxygen consumption following the administration of insulin was prevented when the blood sugar was maintained by an injection of glucose; it was therefore inferred that this effect was not a direct consequence of the presence of insulin, but was secondary to the hypoglycæmia produced by this hormone. The demonstration of the release of adrenaline during hypoglycæmia[3] and the evident sensitivity of rats fed thyroid to this agent would imply that the rise in oxygen consumption after the injection of insulin into such animals may be attributed to the secretion of adrenaline. It would appear, therefore, that the oxygen consumption of hyperthyroid rats may be used as an index of changes in the rate of secretion of adrenaline following physiological stimuli.

I am grateful to Mr. H. E. Tunnicliffe and Dr. R. S. Comline for advice and encouragement, to Sir Bryan Matthews for facilities, and Trinity College, Cambridge, for a grant for this work.

Correlation between the Electrolyte and Water Content of the Organs and Hypertension after Administration of Corticosteroids

IT has been reported that, with renal hypertension, retention of sodium and loss of potassium occurred in the musculature[1–4] and that the same changes in electrolyte metabolism appear after application of hypertension-inducing corticosteroids[5–9]. Therefore these alterations in the inorganic metabolism were considered to be the direct cause of hypertension[10,11]. Tobian *et al.*[12] found an increase in sodium, potassium and water content of the aorta in all forms of experimental hypertension and concluded this to be the cause of hypertension.

In connexion with other researches in the rat, we examined three corticosteroids which influence the electrolyte turnover and the blood pressure in different ways. We also studied their effect on sodium, potassium and water content in the aorta in order to detect which of the changes mentioned above in the electrolyte concentration is related to the blood pressure. The corticosteroids used were deoxycorticosterone acetate (5 mgm./100 gm. body-weight on the first day, then 2·5 mgm.), cortisone acetate (the same dosage) and aldosterone acetate (0·025 mgm./100 gm. body-weight). The treatment lasted 10 days. The daily sodium intake was 75–150 mgm. Sodium, potassium and water content was determined in serum, striated muscle, skin, aorta and in the urinary bladder as another organ containing smooth muscle. With the applied dosage of deoxycorticosterone acetate, the blood pressure remains unchanged in the normal rat (Table 1); as is known, the sodium content of striated muscle is increased and the potassium content is decreased. In the aorta, both sodium and water concentration were increased, whereas the potassium concentration was unchanged.

With adrenalectomized animals the same dosage already produces hypertension. In this case, the sodium as well as the potassium and water content of the aorta is increased; in the urinary bladder an increase in sodium only can be established. It should be emphasized that, by means of the double dosage, hypertension occurs even in normal rats without supplementary supply of sodium chloride.

Cortisone acetate causes hypertension in normal as well as in suprarenalectomized animals. The organs show a depletion of sodium and of potassium, the depletion of potassium being less important than after application of deoxycorticosterone acetate.

It is striking that although the animals survive, the loss of sodium is even more marked than with non-treated adrenalectomized animals. In the aortic wall also the sodium decreases; the potassium, on the contrary, increases strongly.

Aldosterone acetate provokes a retention of sodium in all the organs examined, including the aorta, where the potassium content is almost normal; however, blood-pressure remains unchanged. Thus the experiments show that the variations in sodium concentration of the organs in general or especially in the aortic wall are not conclusive for the production of high pressure.

DOCA, Deoxycorticosterone acetate; CA, cortisone acetate; AA, aldosterone acetate.

The sodium content in the aorta can be high with normal blood pressure or even low with high blood pressure. On the contrary, the retention of potassium increases parallel with hypertension. It is assumed that the increase of potassium in the aorta wall causes a rise of the tension of the vascular muscle and therefore hypertension. In rats the diameter and length of the large vessels were measured by arteriography. The increase in tension to induce the blood-pressure determined was evaluated.

Effect of Potassium on Muscle Tension, especially on that of Vascular Muscle

In the previous communication it was shown that in corticosteroid-induced hypertension in the rat, of all the electrolyte shifts, only potassium increase in the aorta wall was characteristic. In striated muscle or in other organs containing smooth muscle, the potassium content either decreases or remains unchanged.

It has been assumed that the increase of concentration of potassium in the vascular muscle causes a tension increase and, as a result, high pressure. Because of this the following experiments were done *in vitro*: (*a*) the effect of potassium on muscle tension; (*b*) qualitative differences concerning the effect of potassium on different muscle types were investigated.

The experiments were especially carried out on carotis strips of cattle, on the musculus rect. abd. of the frog and the rat as well as on the muscle of large intestine of the rat in Tyrode bath, at adequate temperature and with known, variable initial tension. The changes in tension were registered with a transducer fitted perpendicularly to the surface of the examined tissue.

If the potassium content of the Tyrode solution is increased, the tension of the vessel strip increases too. Contrary to Raab's findings[1] the increase of tension can last up to 90 min. according to potassium content and will last as long as potassium is not changed (Fig. 1).

The latent period, the steepness of the tension increase and the total tension depend on the potassium of the bath solution. The maximal tension is attained with a concentration of 60–70 m*M* (Fig. 2). An equilibrium between the bath solution and the extracellular space is established after about 5 min. The increase in tension initiated by potassium and the decrease after removal of it are not influenced by the oxygen content of the bath solution, as is the case with tension caused by electric stimulation or epinephrine. The influence of potassium on striated muscle or on smooth muscle is different. With skeletal muscle as well as with smooth muscle of large intestine only a temporary increase in tension could be produced with the concentrations used. In the muscle of large intestine 30 m*M* potassium first produces an increase in tonus, then a rhythmic fluctuation in tonus.

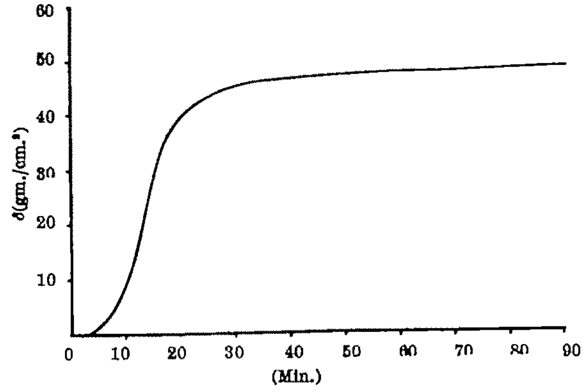

Fig. 1

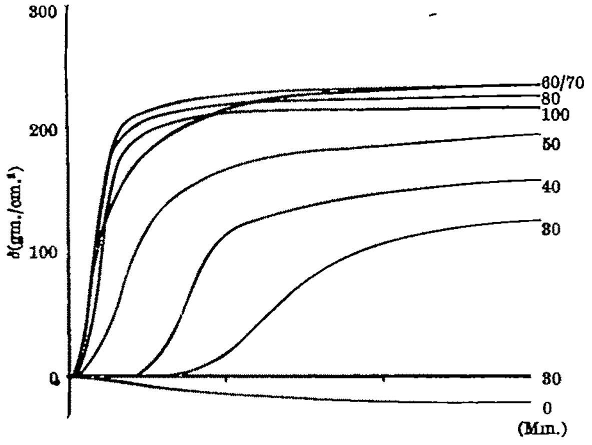

Fig. 2. Course of tension with different concentrations of potassium. Figures on the right indicate m*M* [K]

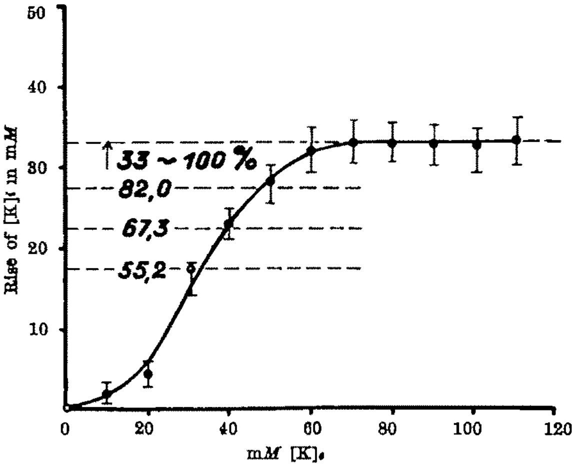

Fig. 3. Abscissa, m*M* in Tyrode solution. Ordinate, m*M* $[K]_i$ increase, after 30 min.

Since on one hand with high-pressure animals the intracellular potassium in the aortic wall is increased, and on the other, as shown, potassium has different effects according to muscle type, the vascular muscle and the muscle of large intestine were examined in regard to their permeability to potassium. The $[K]_i$ was calculated from the total content of K − $[K]_e$. The value of the extracellular space was determined with thiosulphate. As shown in Fig. 3, potassium already penetrates into the vascular muscle when the [K] of the bath solution amounts to 10 m*M* and saturation occurs with a [K] of 60–70 m*M*. If we set the maximum value of the tension increase (Fig. 2) and the $[K]_i$ (Fig. 3) equal to 100, it will be found that the relative tension is proportional to the relative $[K]_i$ (Fig. 3). The course of penetration of potassium into the muscle fibre and of that of tension are similar within a given concentration of the bath solution. No potassium enters the muscle of large intestine of the rat under the same experimental conditions.

It is assumed that two different functional systems are present in the vascular muscle, the contractile system for the transient regulatory tension and the tonic system for the continuous tension. The tension of the contractile system seems to depend on the concentration of potassium in the muscle.

HÆMATOLOGY

Sedimentation of Blood without Anticoagulants

Sedimentation of blood usually occurs only after anticoagulants have been added to prevent clotting and allow time for settling. In devising a technique to study thrombosis *in vitro*[1], an apparatus was made for collecting blood free of tissue thromboplastin and without the addition of anticoagulants. It was incidentally observed that coagulation of blood so collected was delayed sufficiently long for sedimentation to occur. A similar apparatus for collecting blood to study coagulation has been reported by Spaet, Cintron and Kropatkin[2].

Venous blood is drawn directly into a polyvinyl plastic tube through an attached 19-gauge thin-wall, silicone-coated needle. On the end of the tube (opposite the needle) a silicone-coated, three-way stopcock is attached and an additional length of plastic tubing is attached to the stopcock (Fig. 1). As blood flows through the tube, air is pushed out by the advancing column of blood. 2 ml. of blood are allowed to flow out of the tube and are discarded; the end of the tube is clamped and the needle withdrawn from the vein.

No mixing of blood takes place during collection and none of the blood in the tube is exposed to air. By attaching an empty syringe to the stopcock, blood contained in the long section of tubing may be pumped into other containers for further study (Fig. 1). The short section of tubing is clamped off at each end, removed from the stopcock, and hung in a vertical position. The blood in this clamped-off tube will not clot for 1½–2 hr. in most cases and even longer in some instances. Since the blood coagulates so slowly it will settle out rapidly into two distinct layers of plasma and cellular elements (Fig. 2).

The tubing used is a clear polyvinyl chloride plastic tube that measures 0·133 in. in nominal internal diameter (the tubing was kindly supplied by Mead Johnson and Co., Evansville, Ind.). The tubing varies slightly in internal diameter from section to section by volume measurement. 1 ml. fills 10·5–11·4 cm. of tubing. The long section of tubing used is 64 cm. in length and the short section, 28 cm. A total of 10–11 ml. of blood (including discarded blood) usually is withdrawn. The short section of tubing is marked off at 6-cm. intervals, and clamps are attached to separate the blood column into four equal compartments. Sedimentation occurs in all four compartments and the column of clear plasma in the upper compartment is measured at 30 min. Although there usually is some increase in fall after 30 min., most of the sedimentation has occurred by this time and readable values are obtained. The lower three compartments are opened at 1-hr., 1½-hr. and 2-hr. intervals, respectively, to check for the presence of clotting.

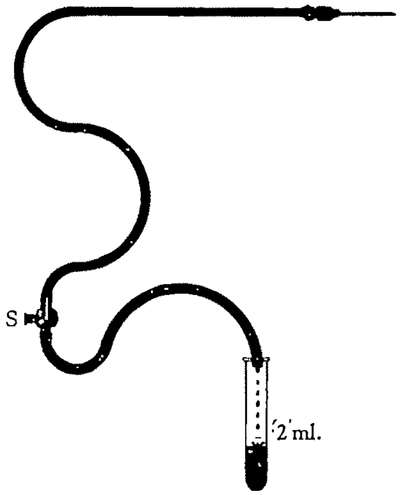

Fig. 1. Diagram of collecting apparatus. (*S*), Three-way stopcock. No suction is required for withdrawing blood. Flow can be controlled by pinching the end of the tube

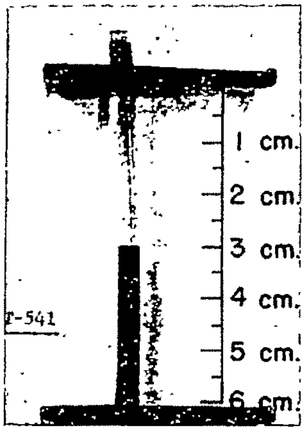

Fig. 2. Sedimentation tube 30 min. after collection of blood from a 52-year-old Negro male with arrested pulmonary tuberculosis. Sedimentation of 3·0 cm. or 50 per cent of the column has occurred. The blood in the upper section beyond the clamp clotted at 45 min. The blood in the enclosed section was not clotted at 2 hr.

Sedimentation-rates have been determined on the blood of 40 male and 71 female patients of the Out-Patient Clinic of the Eugene Talmadge Memorial Hospital of the Medical College of Georgia. Most of the patients were pre-operative and post-operative and a few were prepartum and postpartum cases. The amount of sedimentation in 30 min. averaged 1·8 cm. or 30 per cent of the 6-cm. column in male patients and 1·9 cm. or 31·6 per cent of the column in female patients. In all cases the blood did not clot for 1 hr. or longer. In one instance no sedimentation occurred in 30 min. even though the blood did not clot for 2 hr. The range of sedimentation in 30 min. varied from 0·5 cm. to 4·0 cm. All experiments were done at room temperature, 21–27° C.

Why is coagulation delayed long enough for sedimentation to occur using this method? Several factors are probably important: (1) Silicone-treated metal and plastic tubing are used. Both silicone and plastic provide non-wettable surfaces that retard clotting. (2) Contamination of the blood with tissue thromboplastin is avoided by allowing the first 2 ml. of blood to pass out of the tube during collection. (3) The blood does not make contact with air. According to an early observation of Babington[3], blood collected under olive oil would "enable its red particles to settle more quickly than would otherwise be the case". Müller[4] interpreted this observation to mean that the delayed coagulation was due to exclusion of air. In the method here reported, all air is excluded from the sedimentation tube because air is pushed out of the tube during collection of the blood. The blood in the upper end of the tube beyond the clamp is exposed to air. This blood usually coagulates in 15–45 min. and always coagulates sooner than the blood in the enclosed part of the tube (Fig. 2).

Settling of relatively stagnant blood in blood vessels may be an important factor in the pathogenesis of venous thrombosis, especially in dependent veins of immobilized patients. Fahraeus[5] demonstrated rapid sedimentation of blood in a vein by applying two separated tourniquets on the forearm that was held in a vertical position. In pregnant women or diseased individuals, clear plasma could be obtained in 15 min. by venipuncture just below the uppermost tourniquet. Convincing evidence that settling of blood occurs in horizontal blood vessels in conditions such as stasis has been reported by Harding and Knisely[6]. It is interesting that sedimentation of blood in the apparatus described here was first observed when the tube was horizontal. Settling to the lower side of the tube occurred in a few minutes. Sedimentation of blood as reported here provides a method for studying the suspension stability of stagnant blood *in vitro* without anticoagulants.

The suspension stability of blood is known to be affected by the type and concentration of anticoagulant used in the various sedimentation methods that require anticoagulants[7]. The sedimentation-rate of incoagulable hæmophilic blood can be altered by the addition of heparin or sodium citrate[8]. It is important to know whether or not sedimentation methods using anticoagulants give values paralleling those with the method here described. This method is easily applicable to such a study of both normal and abnormal blood. We are at present using this method to record sedimentation on all specimens of blood used in our *in vitro* thrombosis studies[1], and these results will be reported.

This research was supported in part by a grant from the U.S. Public Health Service, *H*–3973. I wish to thank Miss Marion Hutson and Miss Dorothea Fortson for assisting me in this investigation.

A Fast-moving Hæmoglobin in Hydrops Fœtalis

DURING a study of the hæmoglobins of premature and still-born infants, a fast-moving hæmoglobin was found in a premature baby which clinically showed the symptoms of hydrops fœtalis associated with anæmia, hepato- and spleno-megaly, and which died shortly after birth.

Hæmoglobin analysis of the blood of the fœtus by the paper electrophoretic method as described previously[1] at *p*H 8·6 showed two hæmoglobin spots. One had the mobility of fœtal hæmoglobin, while the other was a fast-moving hæmoglobin, which was much faster than hæmoglobin *A*, slower than hæmoglobin *H* and resembled hæmoglobin *J* and hæmoglobin Fessas and Papaspyrou. At *p*H 6·5, however, *H* and *J* did not separate from hæmoglobin *A*, while the above-mentioned hæmoglobin was clearly separated, and resembled the hæmoglobin of Fessas and Papaspyrou. It was clearly more cathodic than hæmoglobin *H*. It is a pity that we did not have available for comparison the Barth's hæmoglobin, which was described by Ager and Lehmann[2] as being slightly faster than hæmoglobin Fessas and Papaspyrou and faster than hæmoglobin *J* at *p*H 8·6.

The unusual component in the fœtus mentioned above formed the major component, contrary to what has been found up to now in all the cases of newly born infants carrying a fast-moving hæmoglobin component. The amount of alkali-resistant hæmoglobin examined by the method of Singer *et al.* (1951) was found to be 44·3 per cent of the total amount of hæmoglobin.

The symptoms found in the fœtus closely resembled those seen in hydrops fœtalis caused by antagonism between infants and mother's blood.

Also the pathological signs in the grossly enlarged placenta were those seen in hydrops and erythroblastosis fœtalis. There were no indications of antagonism between mother's and infant's blood. However, both parents showed hæmatological abnormalities resembling those found in thalassæmia minor. No pathological hæmoglobin was detected in either parents. The alkali-resistant hæmoglobin was within normal limits.

This is, so far as we know, the first report of a case of hydrops fœtalis associated with the presence of an unusual hæmoglobin.

PLANT PHYSIOLOGY

Relation of Sugar Content to Frost-Hardiness in Plants

IT has long been said that in various plant cells there is an apparent correlation between the sugar content and frost-hardiness. Because of the difficulties in artificially introducing the appreciable amount of sugar into the plant cell, direct evidence has not yet been obtained to show whether the increase in sugar content is the main cause of the frost-hardiness in plant cells or not.

In artificial frost-hardening of the parenchyma cells in cortex of mulberry tree with a constant length of hardening period, the lower the temperature to which material is exposed, the greater the effectiveness of the hardening treatment becomes. At a definite temperature a relatively longer period of the treatment is more effective than shorter ones within certain limits. In all these experiments, the increase in frost-hardiness of parenchyma cells is closely proportional to that in their sucrose concentration, but the former is not accompanied by any increase of their soluble protein provided that they are artificially chilled[1].

It becomes necessary, however, to distinguish the effect of low temperature itself and that of the increase in sucrose concentration in considering the frost-hardening process in plant cells as a result of artificial chilling. When pieces of twig cut from a mulberry tree in April were gradually desiccated at room temperature (about 20° C.) for 2–3 days, considerable changes[2] took place in the cortical tissues; namely, decrease both in water content (12 per cent per dry weight) and in starch content (32 per cent per dry weight), increase both in sucrose (50 per cent per dry weight or 83 per cent per wet weight) and in the osmotic concentration (0·35→0·53 *M* sodium chloride). When these pieces of twig were frozen at − 10° C. and − 20° C. for 24 hr., the percentage of survival of the parenchyma cells in the twig pieces was 100 and 70, respectively, but that in normal twig (undesiccated) was 25 and 0, respectively. The cells desiccated at room temperature showed greater increase in frost-hardiness as well as in sucrose concentration than the parenchyma cells in the twig pieces which were chilled at 0° C. for 10 days at that time.

Pieces of twig upon which artificial frost-hardening had been effective[1] were kept about 20 days at 15° C. without desiccation (enveloping them with vinyl sheet) in order to use up the starch granules in the parenchyma cells. Afterwards, these pieces of twig were chilled for 10 days at 0° C., but the parenchyma cells in these twigs did not increase in frost-hardiness or in sucrose concentration. Thus, even at a relatively higher temperature (20–25° C.), the increase in sucrose concentration in the parenchyma cells also resulted in rise of their frost-resistance. On the other hand, whenever any chilling in parenchyma cells resulted in no increase in their sucrose concentration, they could not be hardened further by chilling. These results seem to indicate that, at least in the mulberry tree, low temperature itself has no direct effect on the increase in frost resistance; but the increase of sucrose concentration may be a primary factor in frost-hardiness.

Furthermore, some experiments were made to find out whether the increase of sucrose concentration in plant cells directly results in an increase of their frost-hardiness or not. In order to increase the sucrose content in a cell, twigs of gardenia (*Gardenia jasminoides* Ellis) with 2–3 leaves in September and October (the leaves can withstand freezing at − 5° C. for about 16 hr.) were put in the glucose solution (0 7 *M*) at 25° C. for 24 hr. At the same time, the twig of the control was put in water under the same conditions as mentioned above. The osmotic value of the spongy or the palisade mesophyll cells in a leaf of gardenia was 0·7–0·75 *M* (indicated on the basis of sodium chloride). Osmotic concentration, sugar content and degree of frost-resistance in the palisade and spongy parenchyma cells in leaves of the twig treated in glucose solution or in water are shown in Table 1.

Table 1. EFFECT OF GLUCOSE UPTAKE ON FROST-HARDINESS IN LEAF CELLS

Treatment	Osmotic concentration† in cells after treatment	Changes in osmotic concentration in cells after treatment	Sugar content in leaves* (per wet weight (gm.))	Percentage of survival after freezing for 24 hr.	
				at −10° C.	at −15° C.
Water (control)	0 7 *M*	−0·05 *M* (decrease)	0·018	0	0
Glucose solution (0 7 *M*)	1 20 *M*	+0·50 *M* (increase)	0·036	100	80

* Exclusive of nerve fraction.
† Mol. indicated on the basis of sodium chloride.

After the treatment the actual increase of osmotic concentration in the cells amounted to about 20–25 atm., with concomitant considerable rise in their frost-hardiness. Furthermore, some other sugars besides glucose, namely, xylose, sucrose, maltose and raffinose, were also found to be able to penetrate into the cells. In such a case, these sugars showed some protective action against freezing injury in gardenia leaf cells.

It is obvious from these results that the increase of sugar content in a cell results in that of its frost-hardiness.

In addition, polyols (ethylene glycol, glycerol and mannitol) and acetoamide also showed a protective action against freezing in gardenia leaf cells, but inorganic salts did not.

Damaging Effect of Drying on *Vicia faba* Seeds

IN studies of radiation damage in seeds it has been shown that very dry seeds are more radiosensitive than seeds of medium water content[1,2]. This finding initiated a number of detailed investigations into the radiobiology of very dry seeds to obtain further information on the damaging mechanism of the radiation[3-5]. It has generally been assumed in these studies that drying itself has no harmful effect on the seeds and, for the frequently used barley, this certainly seems to be true according to Caldecott[1], Ehrenberg[2] and Wellington (personal communication). In other species, however, the situation may be rather more complicated. Thus in an earlier paper[6] it has been shown that drying of *Vicia faba* seeds over calcium chloride at 20° C. for 14 days reduces germinability to about 60 per cent and slows down root and shoot growth considerably. Further study of these effects is clearly most important for radiation work in seeds. The effects in *Vicia faba* seeds have, therefore, been investigated in rather more detail.

Seeds of an inbred line of *Vicia faba* var. *minor*, 'Throws M.S. Winter Beans' from Hasler and Co., Ltd., Dunmow, Essex, were used for the experiments. The beans were kept in desiccators in a single layer for periods up to 4 weeks at 20 ± 0·5° C. over the following substances: $NaHSO_4.H_2O$ (laboratory reagent, relative air humidity 52·0 per cent), $CaCl_2.6H_2O$ (analytical reagent, relative air humidity 32·3 per cent), $CaCl_2$ (laboratory reagent, relative air humidity 2·5 per cent).

Water content is sometimes deduced from the conditions and time of storage in desiccators[4]. It was, however, considered necessary to measure the water content of each sample because it is dependent not only upon the time of storage and the drying agent, but also upon the number of seeds and the volume of the desiccator and other factors. The water content was measured after various periods of storage by crushing samples of 10 beans and drying at 105° C. to constant weight. The measured water content of the various samples used in the experiment varied between approximately 12·0 per cent for beans stored in the room to 7·5 per cent after storage for 4 weeks over calcium chloride, the equilibrium water content over this agent being about 4·5 per cent[7].

For germination experiments samples of 30 beans were soaked at $20 \pm 0{\cdot}5°$ C., after pricking the testas, for an initial 16 hr. in aerated demineralized water, and for a further 3 days in aerated tap-water with constant supply (about 12 l./hr.). The number of beans germinated was then counted, the criterion for germination being taken as visible splitting of the testa over the tip of the radicle.

For growth measurements, 20 germinated beans (where possible) from each soaked sample were suspended by means of a perforated 'Perspex' shelf in aerated circulating tap-water (constant supply of about 12 l./hr.) in a controlled-temperature water-bath run at $20 \pm 0{\cdot}5°$ C. After growth for 8 days, root and shoot length were measured. The beans were stored in darkness except for the final pricking, and soaked and grown in darkness except for 5 min. daily at less than 20 ft. candles. These short exposures to light should not affect the ultimate length of the shoot[8].

The scatter diagram for germination percentage in relation to water content (Fig. 1) shows that germination is progressively reduced as the seeds are dried. The correlation coefficient calculated from the results is $+ 0{\cdot}789$, which for normally distributed data would be very highly significant ($P < 0{\cdot}001$). Fig. 2 shows the effect of drying on root and shoot growth. A sigmoid curve would be expected and free-hand curves have been drawn in to assist the eye.

Schoorel[9] has pointed out that it cannot be taken for granted that seeds in general maintain their quality better at low moisture-levels, but that some species from temperate zones as well as a number of tropical species have a relatively high water optimum water-content for storage. Evidently *Vicia faba* belongs to the latter category ; the seeds cannot b dried much below their normal water content withou injury. It may well be that other seeds used in radic biological experiments have similar properties.

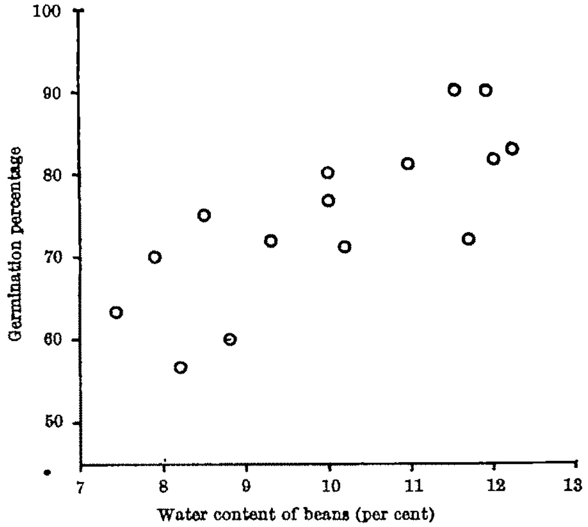

Fig. 1. Germination percentage of *Vicia faba* seeds after soaking for 16 hr. + 3 days, related to water content before soaking

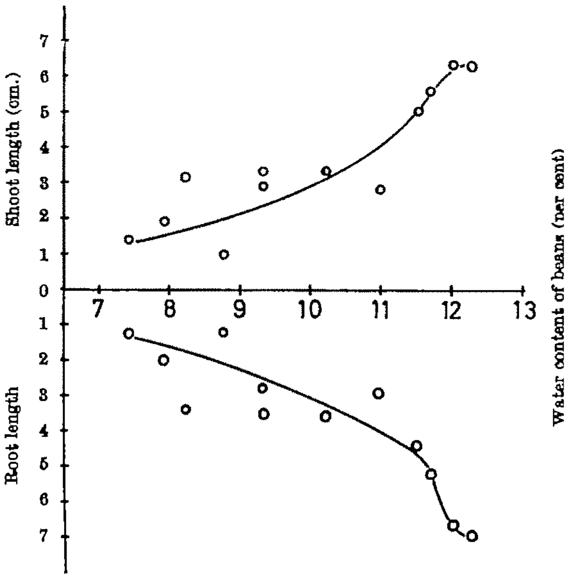

Fig. 2. Root and shoot length of *Vicia faba* after soaking seeds for 16 hr. + 3 days and growing for further 8 days, related to water content before soaking

There appears at present to be no explanation c this harmful effect of drying on seeds. It had nc escaped us that there might be some direct connexio between this phenomenon and the induction b drying alone of free radicles in the testa[7,10]. Thi however, appears to be unlikely, as we have found tha removal of the testa before drying does not appre ciably reduce the final damage.

The results clearly show that in radiobiologic work on dry seeds the effect of drying alone on th seeds may be an important factor to be taken int account in the design and interpretation of exper ments.

We wish to thank Dr. P. Wellington of the Nation Institute of Agricultural Botany, Cambridge, fc discussions of the problems involved, and Pro W. T. Williams of this Department for advice. HISTOLOGY

Reciprocal Relationship of Phosphorylase and Oxidative Enzymes in Skeletal Muscle

WHILE investigating various enzyme systems in a series of dystrophic and normal human muscles we observed that individual fibres showed a reciprocal relationship between phosphorylase and oxidative enzyme content. Although other workers have investigated the oxidative enzyme systems of normal[1-3] and dystrophic[4] muscle, no observations have been made on the relationship between the two enzymes.

Biopsies were obtained from the lateral head of the gastrocnemius in fourteen cases of progressive muscular dystrophy of the Duchenne type ('pseudohypertrophic' muscular dystrophy) and six normal children. All specimens were immediately quenched in liquid air, stored at − 70° C., and cut within a few hours on a cold microtome at − 20° C. and at 10–15μ.

In an attempt to explain the findings in human muscle a number of different muscles from the rat, pigeon, toad (*Xenopus*) and goldfish were also examined.

The methods employed were those for diphosphopyridine nucleotide and triphosphopyridine nucleotide diaphorases[5]; diphosphopyridine nucleotide-linked β-hydroxybutyrate, *iso*citrate, malate, glutamate, α-glycerophosphate, alcohol and lactate dehydrogenases and triphosphopyridine nucleotide-linked *iso*citrate dehydrogenase[6]; succinate dehydrogenase[7]; cytochrome oxidase[8] and glucosan phosphorylase[9].

With the exception of β-hydroxybutyrate dehydrogenase, all the oxidative enzymes and phosphorylase were active in both normal and dystrophic human muscle. Diphosphopyridine nucleotide-diaphorase and lactate dehydrogenase were the strongest.

In dystrophic muscle the majority of abnormally large fibres (100–200μ) reacted weakly for all the oxidative enzymes and strongly for phosphorylase, while the small atrophic fibres (20–30μ) tended to react strongly for oxidative enzymes and weakly for phosphorylase (Fig. 1*A* and *B*). The normal muscle showed a similar variation (Figs. 2 and 3). Longitudinal sections established the uniformity of reaction throughout the length of a fibre.

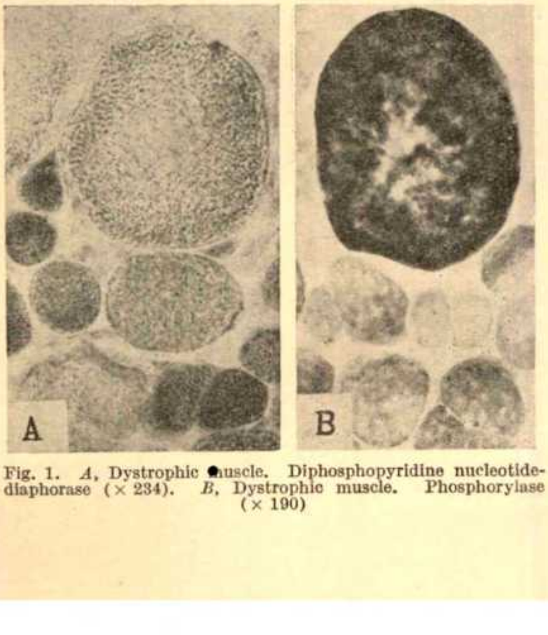

Fig. 1. *A*, Dystrophic muscle. Diphosphopyridine nucleotide-diaphorase (× 234). *B*, Dystrophic muscle. Phosphorylase (× 190)

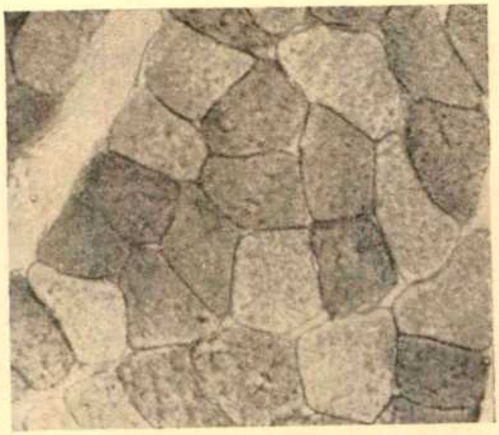

Fig. 2. Normal human tibialis anterior. Lactate dehydrogenase (× 208)

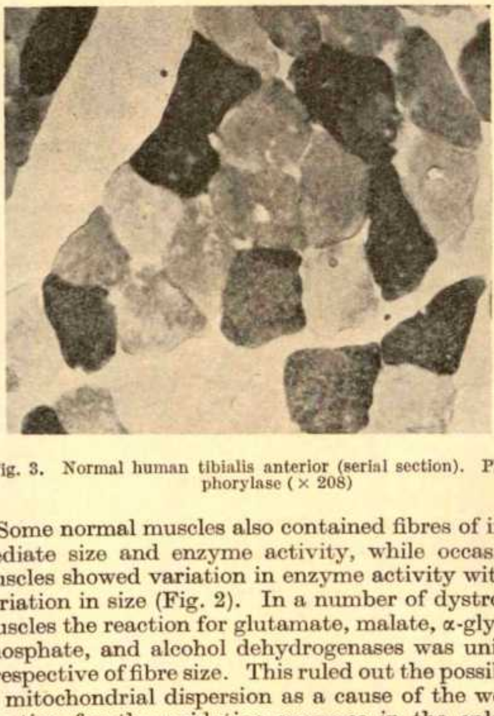

Fig. 3. Normal human tibialis anterior (serial section). Phosphorylase (× 208)

Some normal muscles also contained fibres of intermediate size and enzyme activity, while occasional muscles showed variation in enzyme activity without variation in size (Fig. 2). In a number of dystrophic muscles the reaction for glutamate, malate, α-glycerophosphate, and alcohol dehydrogenases was uniform irrespective of fibre size. This ruled out the possibility of mitochondrial dispersion as a cause of the weaker reaction for the oxidative enzymes in the enlarged fibres.

It appears, therefore, that normal human muscle is composed of two types of fibre; one, generally of smaller diameter, is strong in intramitochondrial oxidative enzymes and weak in phosphorylase, while the other, usually larger, reacts conversely. The atrophic and hypertrophic fibres in muscular dystrophy correspond to these two types respectively. This observation may explain why in muscular dystrophy some fibres hypertrophy while others atrophy. Variations in the proportion of the two types of fibres may account for the earlier and more frequent involvement of certain muscle groups by the dystrophic process.

A reciprocal relationship between phosphorylase and oxidative enzyme activity with the corresponding variation in fibre size was also demonstrated in the muscle fibres of the rat and pigeon. Different muscles contained varying proportions of the fibre types.

The pectoralis muscle of the pigeon, a red muscle, consisted mainly of small fibres (20–35μ) rich in oxidative enzymes and poor in phosphorylase. It contained a few large fibres (40–50μ), with converse activity, located at the periphery of the muscle bundles.

In the toad and goldfish the small fibres were strong in oxidative enzymes as well as phosphorylase, while the large fibres were weak in both enzyme systems. All the muscles of the toad and the white muscles of the fish contained small, intermediate and large fibres. The red muscle of the fish is composed entirely of strongly reactive small fibres.

Assuming that phosphorylase reflects the ability to utilize and synthesize glycogen, it seems that in the larger muscle fibres in warm-blooded animals intrinsic glycogen is the main source of energy. The smaller fibres preferentially use the various substrates of the Krebs cycle. The high lactate dehydrogenase activity in muscle suggests that not all lactic acid produced in muscle is transported to the liver for further oxidation.

In the case of phosphorylase it is known that the inactive precursor is activated during contraction and by such procedures as freezing. The possibility therefore exists that one type of fibre may be preferentially activated.

On the other hand, the reciprocal enzyme activities may represent different phases in a cycle of activity associated with different states of contraction. This would explain the occurrence of fibres of intermediate size and activity. It seems impossible, however, for the hypertrophic and atrophic fibres in dystrophic muscle to be merely different phases of activity of the same fibre type.

The muscle of the fish and toad differs from the muscle of warm-blooded animals in that some fibres are strong in oxidative enzymes as well as phosphorylase, while others are weak in both. The marked variation in diameter between the fibres of different enzyme activity supports the view that these fibres are of different types, as does the consistency of both reaction and size in the red muscle of the fish.

The small muscle fibres with strong oxidative enzyme and weak phosphorylase activity seem to correspond to the red muscle fibres in animals. There is no apparent correlation of fibre types with the fast and slow fibres of amphibia.

A detailed report of this work will be published elsewhere.

Mitotic Pattern and Histogenesis of the Central Nervous System

ROUNDED cells which repeat mitosis adding new cells to the tissue are found at the free margin of developing organs, both in plant and animal. In plants the germinal cells form cambium, while in various animal organs the germinal cells are arranged in an epithelium-like layer at the free margin of the tissues[1].

A typical example is observed in the developing central nervous system or the neural tube (Fig. 1). The germinal layer of the neural tube is called germinal epithelium. The cells in this germinal epithelium are supposed to produce new cells which constitute the mantle layer[2]. Close examination of these cells in the germinal epithelium reveals that: (1) the germinal cells are rounded and always found directly beneath the internal limiting membrane; (2) all the nuclei of the germinal cells show mitotic changes from pro-metaphase to early telophase; (3) their cytoplasm appears clear in a usual stain; (4) the direction of the mitosis is always parallel with the internal limiting membrane.

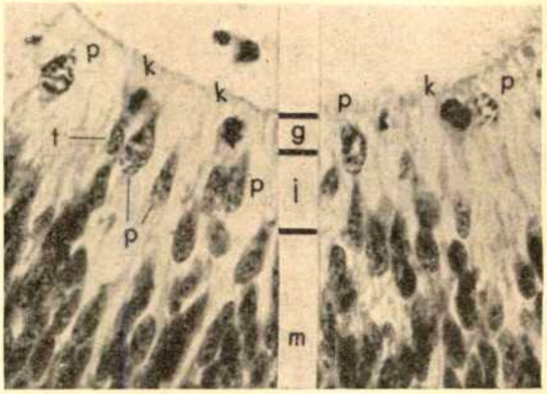

Fig. 1. The wall of the neural tube of the human embryo (C.R., 12 mm.). *g*, Germinal epithelium; *i*, intermediate zone; *m*, mantle layer; *k*, so-called germinal cell showing mitotic nucleus; *p*, prophase nucleus; *t*, nucleus of late telophase

Where an intermediate zone with sparse nuclei exists between the germinal epithelium and the mantle layer (Fig. 1), no resting cell is found in the germinal epithelium; whereas the resting cells are packed densely in the mantle layer. In the intermediate zone between the germinal epithelium and the mantle layer, nuclei at the latter half of telophase and early prophase are to be found. The prophase nucleus is swollen and enlarged, and the telophase nucleus is smaller[3]; but these nuclei in the intermediate zone show smooth transition to the resting cells in the mantle layer on one hand and to the mitotic germinal cells in the germinal epithelium on the other.

These observations can be explained if we assume that the following changes (Fig. 2) occur in sequence as the cells undergo mitosis. The resting cells in the mantle layer rise toward the internal limiting membrane as the cell begins to divide. (The emigration of the germinal cells to the internal limiting membrane during mitosis is considered to be associated with the cytoplasmic changes which round off[4] the mitotic cells, releasing them from the adjacent cells.) The cytoplasm of the cells becomes rounded and takes up less stain than usual. (The rounding off

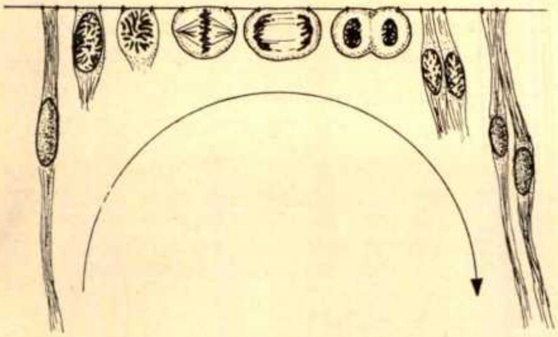

Fig. 2

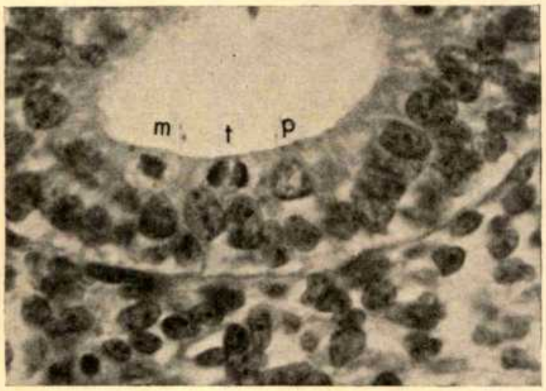

Fig. 3. Mitotic figures in the intestine of the same embryo as Fig. 1. *p*, Prophase nucleus; *m*, metaphase nucleus; *t*, telophase nucleus

of the mitotic cells seems to be related to the solution of the cytoplasm[5,6] and to insufficient supply of adenosine triphosphate to the contractile system in the cytoplasm during mitosis[7].) The chromosomes separate in the direction parallel with the internal limiting membrane, and, when the cells have passed through mitosis, they move back to the mantle layer.

Though this interpretation of cell migration has already been suggested by Sauer[8], his claim and the presence of the same mitotic pattern in a great variety of organs have never attracted attention. I have found this same mitotic pattern (as mentioned in (1)–(4) above) in the following tissues: *Adults*: the epithelium of the efferent duct of the epididymis; the gastric mucosa; the intestinal mucosa; the epithelium of the endometrial gland. *Embryo*: the epithelium of the branchial clefts; the tracheal and lung anlage; the gastric mucosa; the intestinal epithelium (Fig. 3); the epithelium of the bile duct system including the gall-bladder; the epithelium of the pancreas (these six tissues are of endodermal origin); the mesonephric tubule; the mesonephric duct; the metanephric tubule; thickened part of the mesothelium (these four are of mesodermal origin); the epithelium of the nasal pit; Rathke's cleft; the anlage of the retina; the neural tube (these four are of ectodermal origin). The same mitotic pattern is found without distinction of germ layer origin. What is common in these tissues is the fact that they consist of a single layer of cylindrical epithelium. Though the neural tube seems to be many-layered, it can be clearly demonstrated, using Golgi's silver method, that the wall of the tube is actually a modified single-layered epithelium (Fig. 4). Therefore, we conclude that the so-called germinal cells in these epithelial tissues including the neural tube are, in fact, not cells *sui generis* but the actual cells of the epithelium in mitotic phase.

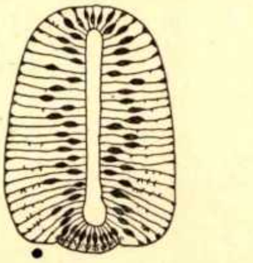

Fig. 4. Cord of chick embryo of the third day, stained by Golgi's method (after Cajal)

Concerning the development of the neural tube, this conclusion introduces a new point of view to the concept of the early histogenesis of the central nervous system, namely, the resting cells in the mantle layer that have been called ependymoblasts and primitive spongioblasts are nothing but the 'germinal cells' in the resting state. This concept, it is believed, contributes to the clearer understanding of the problem of the histogenesis of neurectodermal tumours[9] and of the regeneration of the central nervous system[10].

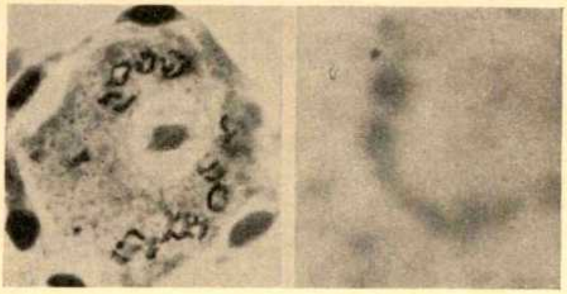
BIOLOGY

Electron Microscopy of the Golgi Apparatus

It has become customary in studies of the nerve cell by electron microscopy to apply the term 'Golgi apparatus' to appearances suggesting membranes, granules, or vacuoles[1]. In size, general configuration and osmiophilia the objects so designated cannot readily be recognized as forming part of the large intracellular 'network' familiar to workers with the light microscope. Moreover, adequate controls of these observations are prevented by the short periods (2–12 hr.) of osmication usual in the preparation of tissues for electron microscopy. As is well known, tissues must remain in osmic solutions for days or weeks before the capricious impregnation of the Golgi apparatus results. Further, it has been suggested that the initial buffering of the osmium fixative used in electron microscopy prevents for some reason the classical 'black reaction' of Kopsch (Gatenby, J. B., personal communication, 1958).

After experimentation, this difficulty has been circumvented and it has been found possible to view



(a) (b)

Fig. 1. *a*, Golgi network in light microscope photograph of a nerve cell (control). Palade fixation with post-osmication 30 days (× 1,200); *b*, portion of the Golgi net (thin section) photographed with the light microscope and further enlarged to × 10,000 for comparison with Fig. 2

with the electron microscope nerve tissues, known from light microscope controls to have undergone the necessary Kopsch reaction. Considerably lengthened schedules of osmication (30 days) followed by soaking in distilled water at 37° C. resulted in adequate impregnation of the apparatus in the controls, while preserving satisfactory fixation of the cytoplasm at the level of resolution of the electron microscope.

Fig. 1*a* is a photomicrograph at (× 1,200) of a dorsal root ganglion cell of a kitten that was fixed in buffered osmium (Palade fluid), and after post-osmication was embedded in wax and cut at 7μ. The cytoplasm is filled with the blackened networks described by Golgi[2]. Fig. 1*b* is from a 2μ section from the same block. In thin sections the network appears as individual thread-like bodies characteristically curved and beaded. One of these bodies photographed with the light microscope is enlarged to × 10,000 for comparison with Fig. 2.

Identically treated pieces of ganglion were embedded in methacrylate and cut to silver/gold sections with the ultramicrotome. On examination with the electron microscope, portions of the Golgi apparatus exactly comparable with those of Fig. 1*b* were easily recognizable during scanning and were selected for micrography (Fig. 2). From an examination of the electron micrographs certain inferences can be drawn.

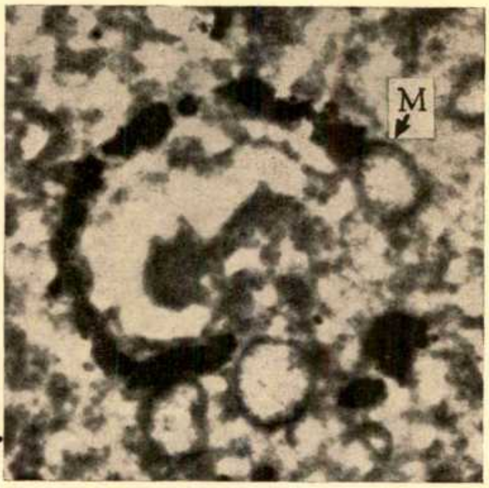


Fig. 2. Electron micrograph (× 22,000) showing Golgi net in close relation to vacuolated mitochondria, *M*

(1) The mitochondria (Fig. 2,*M*) are vacuolated in the kitten and are identical with those recorded by Barton and Causey[3] in ganglion cells fixed for only 2 hr. in buffered osmium.

(2) The mitochondria may be solitary or arranged in aggregates in close apposition like a chain of streptococci.

(3) Segments of the classical Golgi apparatus are clearly recognizable. They appear as a relatively coarse deposition of osmium particles.

(4) This deposition of osmium is unrelated to other 'preformed' structures in the cytoplasm such as the agranular reticulum or the acrosome-like piles of 'parallel plates' described by some workers[1] as the Golgi apparatus in the nerve cell.

(5) A clear space suggesting a shrinkage artefact may accompany the strands of osmium. It does not have a counterpart in the control material.

Repeated observation by the phase microscope on living ganglion cells has consistently failed to visualize any object comparable with the blackened bodies seen in the fixed cells (Figs. 1*a* and *b*, 2). Individual granules or aggregates of granules, comparable with the mitochondria of fixed cells, can however be readily seen. These findings will be discussed and a more extensive publication of the micrographs will appear elsewhere.

I wish to thank Dr. H. D. Purves for assistance and the Medical Research Council (N.Z.) for facilities.

Abbreviated Development in a Pinnotherid Crab

ATKINS[1] has described the post-embryonic development of two British species of *Pinnotheres*. In *P. pisum* there are four zooeal stages and one megalopa, and in *P. pinnotheres* there are two zooeæ and a megalopa. In *P. pisum* the megalopa stage was reached six weeks after spawning and in *P. pinnotheres* it was reached after an interval of 21–26 days. Atkins quotes Sandoz and Hopkins[2] and Hart[3] to the effect that *P. ostreum* takes 21 days from hatching to megalopa and *P. taylori* 28 days from hatching to young crab.

P. moseri Rathbun is a tropical crab found in the atrial cavity of a large simple ascidian, *Ascidia nigra*. Recent observations show that the post-embryonic development of this crab is unusually rapid. Two berried females brought into the laboratory on October 21, 1959, liberated zooeæ during the nights of October 28 and 30, respectively. In both cases the zooeæ correspond closely to the fourth zooeal stage of *P. pisum* as described by Atkins, with the exception that the rostral spine is short, and lateral spines are absent. There are four swimming setæ on the maxillipeds and the thoracic limbs are well developed, the first pereiopod being chelate: in living specimens the thoracic limbs tend to be hidden under the carapace (Fig. 1).

The first batch of zooeæ moulted to megalopas in the early morning of October 30, giving a maximum

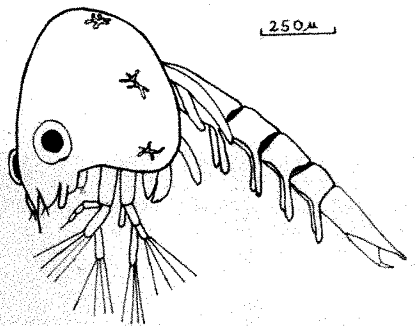

Fig. 1. *Pinnotheres moseri*, newly hatched zooea drawn from a living specimen with the abdomen extended. Four of the thoracic appendages are visible and also portions of the right maxillipeds appearing below those of the left side

time between hatching and attainment of megalopa of 36 hr. In the second batch of larvæ moulting to the megalopa was first seen at 17.30 hr. on October 31, thus giving a maximum of about 24 hr. from hatching to megalopa. As both batches hatched during the night the exact times are not known. The larvæ in both cases were kept at about 29° C., which was within 1° C. of sea water temperatures in October.

The post-embryonic development of *P. moseri* is thus considerably abbreviated when compared with what is known of other species of Pinnotheres. The significance of such abbreviation cannot at present be assessed; but it is pertinent to point out that *Ascidia nigra* is confined in its distribution to sheltered water such as enclosed bays and lagoons and is absent from communities of animals in more open areas. If *P. moseri* is an obligate commensal in *A. nigra* and cannot live in other hosts, an abbreviated larval development might be advantageous in preventing the larvæ from dispersing too far away from the concentrations of its host population.

Calcium–Lithium Competition in Absorption by Plant Roots

In the process of absorption by plant roots, different ions may compete with each other, may fail to compete, or finally, one kind of ion may increase the rate of absorption of another. These specificities are considered due to the existence of specific binding sites on carriers which transport the ions across cellular membranes. Examples of mutually competing ions are the pairs potassium–rubidium[1] and calcium–strontium[2]. Neither sodium nor lithium competes readily for the potassium–rubidium sites, at low to moderate concentrations, and magnesium is bound loosely if at all by the sites which transport calcium and strontium.

In work with plants, all reported cases of specific mutual competition among mineral ions have involved pairs of ions closely related chemically. However, calcium severely inhibits the absorption of lithium by barley roots (ref. 3 and Epstein, E., unpublished work), and it has now been determined that the interference is competitive, indicating identical binding sites for these two ions.

Barley, variety Arivat, was grown in dilute calcium sulphate as described earlier[2]. The absorption experiments were conducted with 1-gm. portions of excised roots in 100 ml. volumes of aerated solutions at 30° C., for 60 min., during which absorption was a strictly linear function of time. The concentration of lithium chloride was varied from 1·0 to 10·0 m.moles/l., in the absence and presence of calcium sulphate at 1×10^{-4} and 1×10^{-3} *M*. The roots were rinsed, ashed at 500° C., and lithium in a solution of the ash was determined by flame spectrophotometry at 671 mμ. In Fig. 1, the reciprocal of the rate of absorption, v (in μmoles/gm./hr.), is plotted against the reciprocal of the lithium concentration, S (in m.moles/l.). In the presence of calcium, the slope of the line increases without change of the intercept, indicating competitive interference by calcium with lithium absorption.

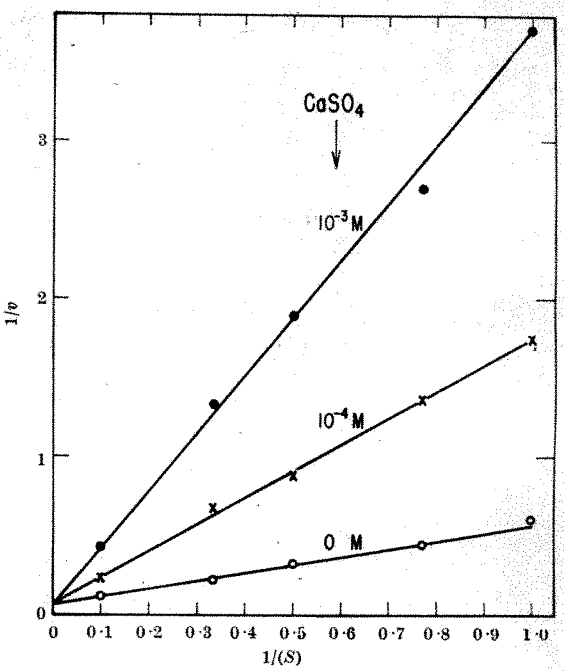

Fig. 1. Competitive inhibition of lithium absorption by calcium

Calcium, which is here shown to inhibit severely and competitively the absorption of lithium, accelerates the absorption of several other ions, among them potassium[4] and rubidium (Table 1). These findings confirm the earlier conclusion[1], recently questioned by Sutcliffe[5], that there are sites transporting lithium which are distinct from others which transport potassium and rubidium, calcium strongly competing with lithium for the former sites while increasing the rate of potassium–rubidium transport.

Table 1. Effect of Calcium on Absorption of Rubidium by Barley Roots

$CaCl_2$, *M* × 10^3	0	1	2	5	10	25
Rb* uptake, μmole/gm. fresh wt./hr.	8·9	11·8	13·3	14·8	16·0	16·5
$CaSO_4$, *M* × 10^3	0	1	2	5	10	
Rb* uptake, μmole/gm. fresh wt./hr.	8·9	9·8	11·1	11·0	11·8	

* Rubidium chloride, 1×10^{-3} *M*. Rubidium labelled with rubidium-86, assayed by determination of the radioactivity of the root ash. Experimental conditions and procedures as described in the text for the experiment on $Ca^{++} - Li^{+}$ competition.

At first it seems surprising to find competition between two such dissimilar ions as an alkaline earth cation, calcium, and an alkali cation, lithium. However, it is recognized that the small size and relatively large ionizing potential of lithium cause some resemblance between it and the alkaline earth cations[6]. An instance illustrating this resemblance is the low solubility of the carbonate and phosphate of lithium. Another example concerns the expansion of mica type crystal lattices as it depends on the interlayer cations. Barshad[7] has shown that montmorillonite saturated with lithium is similar in swelling behaviour and differential thermal analysis to samples with alkaline earth interlayer cations, and differs characteristically from samples saturated with the other alkali cations or ammonium ions. Finally, lithium, like calcium, increases the rate of rubidium absorption by barley roots[1].

These similarities seem to reflect ionic properties important in determining the 'fit' of the ions in molecular groupings of ligands. Lithium ions resemble the alkaline earth cations more than the other alkali cations in some of the properties that determine chemical affinities, including affinity for the carrier sites involved in active ion transport.

RADIOBIOLOGY

Resistance of Algae to Radiation

Experiments carried out since 1954 have shown that various algae are much more resistant to radiation than are higher plants and animals. The results, which will be published fully elsewhere, are as follows:

Algae	Author	Dose survived (rads)
Spirogyra	Godward, 1954, and unpub.	20,000 plus
Zygnema, Mougeotia	Prasad, 1959, unpub.	50,000–70,000
Cosmarium	Nizam, 1959, unpub.	70,000
Euglena	Leedale, 1958	150,000
Eudorina	Rayns, 1959, unpub.	100,000
Chlorella	Nizam, 1959, unpub.	two successive doses of 1,000,000
Chaetomorpha	Patel, 1959, unpub.	50,000 plus
Prorocentrum	Dodge, 1959, unpub.	2,000

Of the above, only the last-mentioned, *Prorocentrum*, has the same order of sensitivity as the higher plants, if one excepts their specially resistant parts such as pollen grains and seeds. In all the experiments the algae were maintained in culture as long as possible after radiation; the recovery could follow in a matter of days but might need up to five weeks. Special features of the nuclear cytology probably account for the resistance and rapid recovery of the Conjugales[2,3,5] and *Euglena*[4]. These features do not occur in *Eudorina*, which has, however, very small chromosomes (ref. 1 and Rayns, unpublished work). Smaller still and unresolvable with the visual light microscope except at prophase, and even then uncountable, are those of *Chlorella*, which it seems impossible to kill. On the other hand, the chromosomes of *Prorocentrum* are relatively large, and it would seem that, like those of the higher plants in general, they may have a localized centromere. In those algae where the chromosome organization is conventional or at any rate gross, it seems that resistance to radiation is relatively low. No organism has, to my knowledge, been reported as surviving an experimental dose such as that given above to *Chlorella*, where the recovery process was, however, long; although it seems clear that the marine algae which received considerable radiation from atomic explosions were not killed.

The radiations were carried out at the Medical Research Council Unit, Hammersmith Hospital.

Radiocarbon Dating of Soil Humus

The turn-over of soil organic matter is a much-discussed problem in pedology. Although much has been written about the rate of breakdown of soil organic matter in mull and mor (for references see ref. 1), our knowledge of the turn-over of forest soil humus is very incomplete. This is particularly true of the organic matter in soil horizons below the humus layer.

The radiocarbon dating method opens a way to determine the approximate 'time of residence' in the soil of the organic matter, supposing that this time is of the order some hundred years or more. For this reason three soil samples from a profile in Garpenberg, Province of Dalarna, Middle Sweden, have been studied. The sample plot was a good-growing 95-year old spruce forest on moraine, altitude 200 m. (just above the so-called highest coastline). The samples represented the mor layer (A_0), the leached but humus-coloured top horizon of the mineral soil (A_1), and the brown accumulation horizon (B). The profile, which will be described in more detail in a later publication, is a favourable type of the podzol profile; similar profiles are not uncommon on moraine soils in this region.

The samples were passed through a 3-mm. sieve leaving stones, gravel and all but the finest roots on the sieve. The sifting process passed 63 per cent of the A_0, 90 per cent of the A_1 and 76 per cent of the B layers, based on samples collected in the field (measured dry).

The loss on ignition was 45·5 per cent of the A_0 sample, 15·9 of the A_1 and 5·2 of the B sample. In A_0 and A_1 the loss on ignition can be considered as estimates of the organic matter content, which, however, is lower than 5·2 in the B horizon.

The residual carbon-14 activity was measured with the following results:

Tree rings of oak grown 1845–1855 in Stockholm. Corrected for decay up to 1959	100·0 ± 0·3 per cent
St. 472, Sample A_0	98·3 ± 0·5 ,,
St. 473, Sample A_1	98·0 ± 0·5 ,,
St. 474, Sample B	95·6 ± 0·5 ,,

The activities have been corrected to the same initial isotopic composition by measuring the ratio of carbon-13/carbon-12 in all four cases (see Östlund[2]).

Owing to the well-known decrease of carbon-14 activity in the biosphere between 1850 and 1954 caused by industrial fuel combustion (Suess-effect), it is not possible to draw any reliable conclusion about the time of residence for samples A_0 and A_1. Sample B, however, shows a decrease of activity which is larger than the Suess effect. The calculated value for the time of residence is 370 yr., but the experimental errors give a total time-span of ± 100 yr. (95 per cent probability). In addition, the variations of the carbon-14 assay of the biosphere in times also before 1850 (de Vries[3]) add an extra unknown uncertainty.

Considering the fact that the site sampled probably has been covered with forest for about 9,000 years, the relatively low age of the organic matter in the B horizon suggests that the organic matter in this horizon (or a considerable part of it) is continually broken down and re-synthesized from substances coming from above. This is important, because in this and many other forest soil profiles the amount of organic matter in the B horizon equals or exceeds that in the A horizon. Further investigations seem called for, both by radiocarbon measurements and by other methods.

Accumulation of Cæsium-137 by Plants grown in Simulated Pond, Wet Meadow and Irrigated Field Environments

PLANTS grown in nutrient culture[1,2] and aquatic environments[3] accumulate more cæsium-137 than terrestrial plants. The work cited indicates that this isotope should be more available from fall-out under one set of environmental conditions than another. Consequently, the availability of cæsium-137 to plants was examined under conditions simulating shallow ponds, wet meadows and irrigated fields.

The spotted Persicaria or lady's thumb (*Polygonum persicaria* L.), which is tolerant of wide moisture conditions, was transplanted from the field into 7,000 gm. Ephrata Sandy Loam soil[1] in 'Pyrex' battery jars. Stable cæsium was not added to the soil because increased uptake of cæsium-137 with addition of carrier cæsium has been shown[4]. After the plants were well established, 72·3 µc. of $^{137}CsCl_2$ in distilled water was added uniformly to the surface of water or soil, care being taken to avoid contamination of the aerial surfaces.

Plants were grown outdoors under conditions shown in Table 1. There were three pots for each environment and 12 plants per pot. Water-levels in the 'shallow pond' and 'wet meadow' cultures were maintained by adding distilled water with automatic devices while moisture in the 'irrigated field' cultures was maintained by replacing weight loss daily.

Table 1. CONCENTRATION OF CÆSIUM-137 IN PLANTS GROWN IN DIFFERENT ENVIRONMENTS

Environment simulated	Experimental condition	Mean value at 5 hr.* (µc./gm.)	Uptake ratio, field capacity = 1	Mean value at 36 days (µc./gm.)	Uptake ratio
Shallow pond	Saturated soil with 2½ in. standing water	$3·1\times10^{-3}$ ±0·86	75	$1·4\times10^{-2}$ ±0·32	450
Wet meadows	Saturated soil, water table ½ in.	$8·2\times10^{-5}$ ±1·40	2	$8·9\times10^{-4}$ ±0·92	30
Irrigated field	Soil moistened to field capacity	$4·2\times10^{-5}$ ±0·65	1	$3·1\times10^{-5}$ ±0·67	1

* Each mean represents nine samples.

Plant stem tips (apical bud, stem and first two leaves) were sampled at intervals over a 36-day period. Samples were wet-ashed in nitric acid at temperatures less than 500° C. Radioactivity of the samples was measured with an end-window Geiger–Müller tube. Results of sampling at 5 hr. and 36 days are shown in Table 1.

The uptake ratio for plants grown in shallow standing water, saturated and field-capacity soils was 450 : 30 : 1. The high uptake in standing water is in close agreement with results obtained with emergent plants in an aquatic community[3], and not appreciably different from nutrient solution studies[2].

The greater uptake of cæsium-137 by plants grown in soil covered by shallow water and saturated soils is due mainly to the shallow root systems produced by plants in such environments, although some absorption by submerged leaves and stems would be expected. These root systems lie close to the surface in saturated soils, and adventitious roots, as in this experiment, often invade the water proper[5-7]. Thus, cæsium-137 can be absorbed directly from the water before the ions are fixed on to the soil. This is supported by results (Table 1, column 3) which show 20 per cent of total accumulation occurred during the first 5 hr.

The radioactivity of plants grown in field-capacity moisture was not appreciably greater than the level in plants taken from the natural habitat. This confirms reports of low availability of cæsium-137 in drier soils[2].

When applied to fall-out, the results reported here may be of considerable interest. Because uptake via roots is additive to direct fall-out on to the aerial plant surfaces, animals grazing in areas in which a major portion of the forage is from wet-lands may ingest cæsium-137 to 400-fold or more over those grazing on dry-lands. Similarly, crops grown in saturated soils or standing water should contain more cæsium-137 than crops grown on drier soils. Thus, increased accumulation of cæsium-137 from wet-lands may explain deviations from a correlation between rainfall and milk content[8,9] and added root absorption may contribute to the high cæsium-137 content of rice in Japan[10]. Further, a few dairy herds, grazing wet or periodically flooded meadows and edges of shallow ponds, might contribute disproportionately to the cæsium-137 content of a local milk supply, and extensive wet-lands could elevate the contamination-level of a larger region as has been suggested by Russell[11] relative to strontium-90 content of milk in England.

ENTOMOLOGY

Automatic Time/Response Records with *Drosophila*

Drosophila melanogaster Meig. is widely used for bioassay of insecticides. In developing a method for bioassay of insecticide residues in soil, we have found it necessary to use a time/response technique similar in principle to that employed by Callaway, Dirnhuber and Wilson[1]. In comparison with the more usual dose/response techniques, the sensitivity[2] and also the useful range of the assay can be increased by this means. However, with a time/response technique, two main difficulties arise when attempts are made to obtain records at precise times in order to follow accurately a given programme of observations. The response of each group of flies takes a finite time to assess and so, when many groups are involved, discrepancies occur between the desired and the actual times of the counts. Unless allowances are made for these time discrepancies—a tedious process—errors are introduced which can be important when the intervals between the records are small. Furthermore, it is often necessary to record responses throughout a 24-hr. period, or even longer, and this creates an obvious practical problem which, in the past, must have discouraged the use of time/response techniques as routine methods.

A brief description is given below of an apparatus which we have devised to record automatically the response of *Drosophila* at any number of pre-arranged times. The apparatus has worked successfully in this laboratory for the past six months and a detailed description of it is being prepared for publication elsewhere.

Acetone is used to extract the insecticide from the soil. Aliquots of the extracts are applied to 38 × 10 mm. absorbent cotton rolls, and the solvent is allowed to evaporate. A dilute solution of a syrup is added to each roll to provide food for, and so attract, the flies. The treated rolls are suspended in special 130 × 25 mm. 'exposure tubes' and 30 male *Drosophila* are put into each tube. The top of each tube is closed with muslin, but the bottom of the tube tapers evenly towards a 6-mm. diameter exit hole. A ventilation hole, 10 mm. in diameter, is present in the side-wall 30 mm. from the bottom of the tube. Thirty of these tubes are mounted vertically in a rack. In the base of the rack there are countersunk 6-mm. diameter holes into which fit the tapered bottoms of the exposure tubes. These holes are normally kept closed by a sliding shutter which has a complementary set of holes and is fitted underneath the base of the rack. The shutter is linked mechanically to two solenoids which open and close it in response to signals from a special timing device. The rack carrying the tubes is mounted immediately over a 152-mm. diameter cylinder which is coated with a non-setting gum and powered by an internal coiled spring. This can be wound up by a crank arm attached to a stub-axle passing through the end-plate of the cylinder. A pin-escapement, fitted externally to the other end-plate, limits the movement of the cylinder and is also operated by a solenoid activated by a signal from the timer.

The time of each operation of the apparatus is determined by an accurately driven tape in which holes have been punched at intervals to correspond with the required time sequence. An electrical contact detects each hole as it passes and the three signals required to work the solenoids of the apparatus are initiated. There is first a short pulse to open the shutter, followed immediately by a second, slightly longer pulse to close it and then, after a delay of about 5 sec., a third pulse causes the cylinder escapement to be released.

The timer is started as soon as flies have been put into half of the exposure tubes, which takes about 2 min., and, as the flies become affected by the insecti

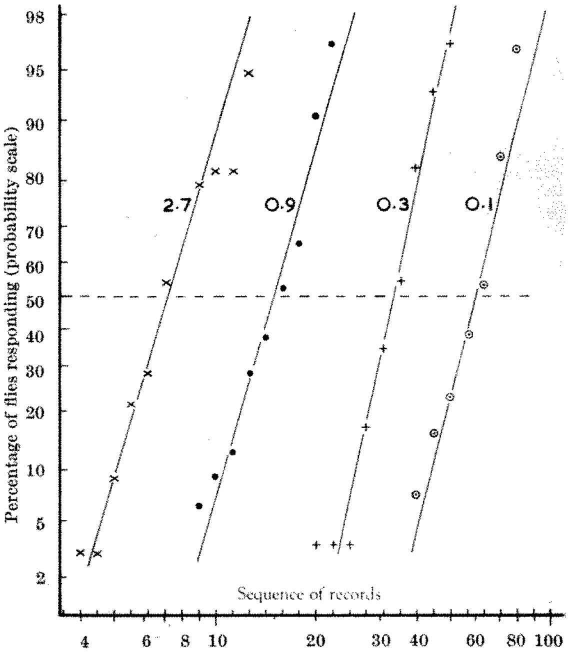

Fig. 1. Examples of time/response curves obtained with the recording apparatus for four standard doses of dieldrin. The figures refer to the dose of dieldrin in µgm. per roll. Temperature, 25 ± 0·5° C.; relative humidity, 72 ± 2 per cent

cide, they fall and collect in the recesses formed by the holes in the base of the rack. The apparatus is illuminated from above so that unaffected flies are attracted upwards and away from the exit holes. At an appropriate time, the shutter moves and opens the exit holes momentarily so that the affected flies fall out on to the sticky surface of the cylinder, where they are retained in discrete groups. The escapement is then released and allows the cylinder to move 1/16 of a revolution into position for the next record. At suitable times the number of flies in each position on the cylinder is noted, and the frequency results so obtained enable the time for 50 per cent response to be estimated in the usual way for each dose. The time/response curves shown in Fig. 1 are examples of results with this apparatus.

The programme of observations should be chosen so that there are equal grouping intervals for response to different doses and thus the programme used depends on the relationship between time of exposure and response to any given dose. Under our experimental conditions:

$$Y = a + b \log t$$

where Y is the probit of the percentage of flies responding to any given dose at time t, a is a function of dose in any one assay and b is the regression coefficient (Fig. 1). This relationship is that usually found when exposure to the poison is continuous[1,3,4] and it was thus necessary to arrange for observations to be made at equal intervals on a logarithmic, and not linear, time-scale; the tape was therefore programmed accordingly.

We wish to thank Mr. J. A. Nelder for numerous fruitful discussions while the apparatus was in the design stage, and also Mr. D. W. Wright for the help and encouragement which he has given throughout the work.

Physiological Age of Codling Moth Females (*Cydia pomonella* (L.)) caught in Bait and Light Traps

SEVERAL recent papers have compared the effectiveness of bait and light traps as means of estimating changes in adult codling moth populations and of timing the application of sprays[1–3]. The comparison of these trapping devices was based, in each instance, on the total number of moths caught over periods considered to have been critical for the subsequent infestation of the crop. In these investigations no attention was paid to the quality of the respective catches beyond noting the difference in the relative frequency of females attracted to each type of trap.

When trap catches are used for recording moth activity as a guide to timing spray application, the age of females in samples may be of little importance if the weather conditions impose a fairly long developmental period on eggs. However, the physiological age of the trapped moths must be carefully considered when interpreting catch results obtained under warmer conditions. This point was emphasized by Nel[4], whose investigations showed that bait trap samples consist predominantly of spent, or half-spent, females.

Some additional information has been gained in the course of an experiment on the performance of bait and light traps carried out in an apple orchard near Canberra, Australia. Four bait traps and one light trap were operated daily in alternating positions from November 1958 until March 1959. A standard lure of fermenting molasses incorporating pine-tar oil[5] was used in the bait traps. The light source was an *HP* 125 W.B.C. mercury vapour lamp. Females obtained from both types of traps throughout the season were fixed and stained according to the method of Hamstead and Gould[6]. Each female was dissected, and an estimate of its physiological age made in strict conformity with Nel's techniques and criteria.

The age distribution of the females caught in bait traps at Canberra was found to be almost identical with that observed by Nel in South Africa. It is thus likely that most females are not attracted to the bait before some of their first-laid eggs have had time to hatch.

Table 1

	Physiological age I (young)	Physiological age II (middle-aged)	Physiological age III (old)	Total
Bait traps	14	39	36	89
Light trap	113	74	11	198

$\chi^2 = 70_{(2)}$ $P < 0{\cdot}001$

The picture is entirely different for the light trap, which drew samples of quite significantly younger females from the field population (Table 1). This feature may be added to the previously recognized advantages of light traps over bait pans in codling moth population studies.

ANATOMY

A Highly Organized Structure within a Neurosecretory Vesicle

PREVIOUS electron microscope studies have demonstrated an abundance of vesicles 1000–3000 Å. in diameter in the terminal branches of neurosecretory axons in the neurohypophysis[1], and in the sinus glands and pericardial organs of crustaceans[2,3]. I have recently observed that some of these neurosecretory vesicles possess a highly organized internal structure.

The pericardial organs of the Mediterranean stomatopod *Squilla mantis* were prepared for electron microscope study by fixation either in buffered

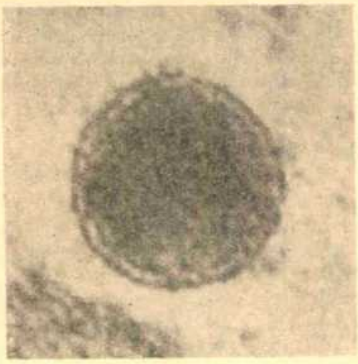

Fig. 1. A single neurosecretory vesicle of type *A* (× 225,000). Material fixed in buffered potassium permanganate, embedded in 'Araldite'

osmium tetroxide or buffered potassium permanganate and subsequent embedding in 'Vestopal *W*' or 'Araldite'.

In these preparations two types of vesicle could be clearly distinguished by their size and electron density and will be referred to here as types *A* and *B*.

Type *A* vesicles are regular in outline, spherical or slightly ovoid, approximately 1500 Å. in diameter. Each is surrounded by a distinct unit membrane, 75–90 Å. in thickness. The contents of type *A* vesicle can only be distinguished with difficulty as they are very electron dense. They appear to consist of tightly packed units without geometrical order, each unit comprising an electron-dense particle approximately 50 Å. in diameter, surrounded by a less dense sheath some 75 Å. in thickness (Fig. 1).

Type *B* vesicles, about 1200 Å. in diameter, are generally irregular in outline, though approximately spherical or ovoid; the bounding membrane is similar to that enveloping the type *A* vesicle, though less distinct, and there is usually a clear space between the membrane and the contents of the vesicle. The type of order displayed by the contents of the vesicle in various projections demonstrated in the electron micrographs is such as to suggest that the organization is based on a precise hexagonal packing of rod-shaped components. In the projection shown in Fig. 2 the structure appears as a series of alternating light and dark bands each measuring 60 Å. in width.

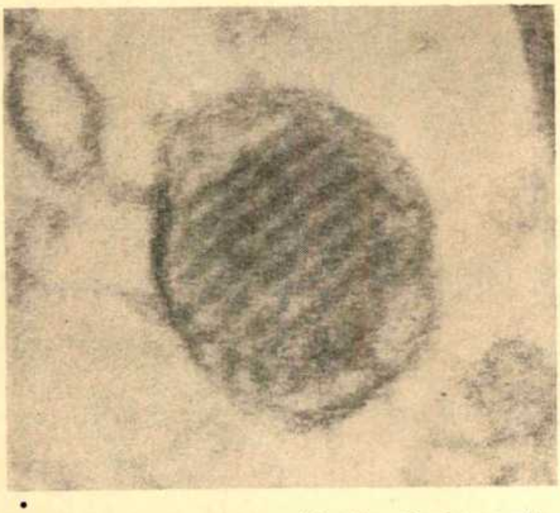

Fig. 2. A single neurosecretory vesicle of type *B* and two smaller vesicles (× 310,000). The orderly arrangement of material in the larger vesicle may be seen, and also a connecting link between the larger and one of the smaller vesicles. Material fixed in buffered osmium tetroxide, embedded in 'Vestopal *W*'

Fibres containing type *B* vesicles also contain smaller vesicles, spherical, ovoid or elongate in profile, approximately 500 Å. in diameter. There are indications that these small vesicles form part of a continuous tubular system in the axoplasm and that the type *B* vesicles are intimately related to this system. Indeed, it seems possible that the material in the type *B* vesicle may form within the system of small vesicles, and that the type *B* vesicles are swollen parts of this system within which material has assumed a crystal-like order.

The detection of orderly differentiated systems within neurosecretory particles is of theoretical interest, for there have been some indications from histochemistry also that neurosecretory vesicles may contain at least two chemical components[4]. The type of organization indicated by the present electron micrographs may, in fact, represent an orderly arrangement of these components which might permit the maximum of interaction between them in a suitable milieu.

'Synaptic Vesicles' in the Neurohypophysis

ELECTRON microscope studies of the neurohypophysis have shown that the terminal branches of the hypothalamo-hypophysial tract fibres contain, in addition to mitochondria, vesicles or granules of two kinds distinguished by their size[1,2]. The larger inclusions each have a diameter of the order of 100–300 mμ (1000–3000 Å.), and are thought to represent the secretory material which may be demonstrated by histochemical means, using the light microscope. The smaller inclusions, with diameters of approximately 30 mμ (300 Å.), have been described as synaptic vesicles[1] because they resemble in size inclusions found elsewhere in the nervous system at nerve terminals.

In the course of studying the neurohypophysis of rats and ferrets with the electron microscope, using material fixed either in buffered osmium tetroxide or in buffered potassium permanganate, we have observed a correlation of vesicle size with fibre size and fibre position. Small fibres, especially those closely applied to capillary walls, generally contain small vesicles, often densely packed and filling the whole outline of the fibre; in such fibres the larger vesicles are either absent or few in number (Figs. 1 and 2). In larger fibres the larger vesicles are found, either alone or with some small vesicles also. Large fibres containing small vesicles only have not been observed.

The correlation of vesicle size and fibre size is in itself not inconsistent with the view that the smaller vesicles are analogous to vesicles found at synaptic terminals. It is significant, however, that when large vesicles are found in fibres closely adjacent to capil

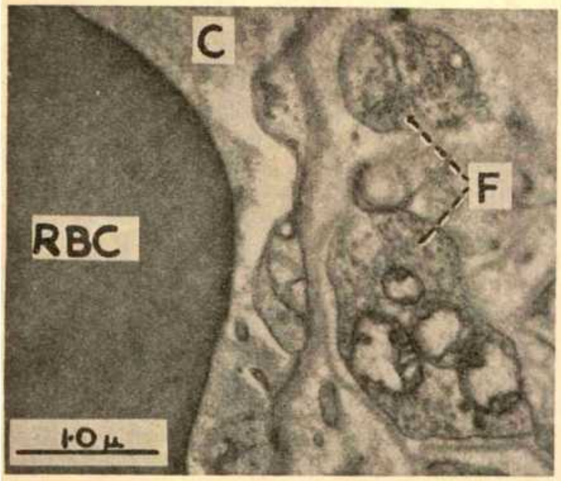

Fig. 1. A small portion of the neurohypophysis of a rat in which neurosecretory fibres (*F*) in close proximity to a blood capillary (*C*) are shown, and are seen to contain only small vesicles and mitochondria. *RBC*, part of a red blood cell. Fixed in buffered potassium permanganate, embedded in 'Araldite'

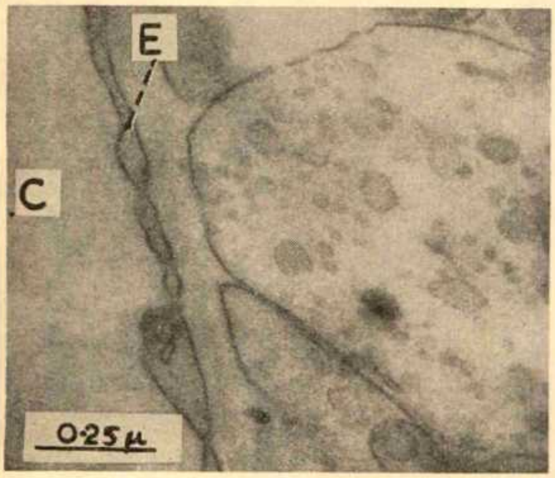

Fig. 2. A similar region in the neurohypophysis of a ferret. Indications of breakdown of large vesicles to small are apparent. *E*, fenestrated endothelium. Fixed in buffered potassium permanganate, embedded in 'Araldite'

aries, an internal structure may be detected in them which indicates that they may contain an aggregation of inclusions of the smaller type. There is, therefore, an interesting parallel between the vesicles in the nerve terminations of the mammalian neurohypophysis, and those in the pericardial organs of crustaceans, in which an orderly arrangement of small vesicles or particles within larger vesicles has been detected (previous communication).

As a result of these findings, we believe that it is imprudent at present to imply[1], by the use of the ame term, that all small vesicles in the terminations of neurosecretory fibres resemble functionally the ynaptic vesicles found elsewhere in the nervous ystem.

ARCHÆOLOGY

A New Palæolithic Find in Tapti Valley, Khandesh, India

In 1863 Foote reported a first palæolith from laterite gravels occurring at Pallavaram, near Madras. This find proved the presence of early man, maybe in the Pithecanthropoid or Neanderthaloid stage in India[1].

De Terra and Paterson[2] later recognized different phases of glacial cycle in Narbada valley. They were able to point out that early Palæolithic 'flake industries' were associated with Middle Pleistocene *Elephas antiqus* and *E. namadicus* and that three different cycles of sedimentation could be distinguished and correlated with the three stages in the formation of Narbada alluvium.

Pierre Teilhard de Chardin[3] of the Wenner–Gren Foundation, New York, points out in his good-will message to the Palæontological Society that "... first care should be taken to organize with the help of a few trained collectors, some kind of permanent surveyance: of the Narbada Basin (for the research of the hand-axes Man of India, skull or limb-bones...). Between S.E. Africa and Java, India happens to hold an exceptionally critical place, as far as the origin of Man is concerned".

During geological and ecological surveys of Khandesh Valley, I came across an interesting spot beside the Girna River bank near Central Railway bridge, 3 miles from Jalgaon, situated 21° 1′ N. and 75° 35′ E., 261 miles north-east of Bombay.

The River Girna rises in the hills west of Kalyan, in Nasik district. It is fed by streams from the northern slopes of the Sapta-Shring Range. After a course of about 150 miles, it joins the Tapti near Nander. Its course lies in equal parts in Nasik and Khandesh. Passing through Nasik almost in a straight line eastwards, its course changes to north-east in Khandesh. Near Jalgaon, it bends north and north-west, flowing for several miles with many windings almost parallel to the Tapti.

The underlying rock formation at places is Deccan trap. On the banks of the River Girna pebble conglomerate abound. They are capped by layers of sandy alluvium. This indicates that the river must have overflowed at times. The river now appears to be eroding ancient beds and underlying rocks.

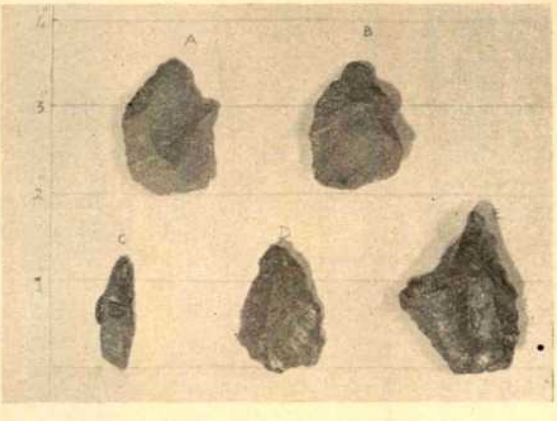

Fig. 1. Scrapers from the Girna River banks

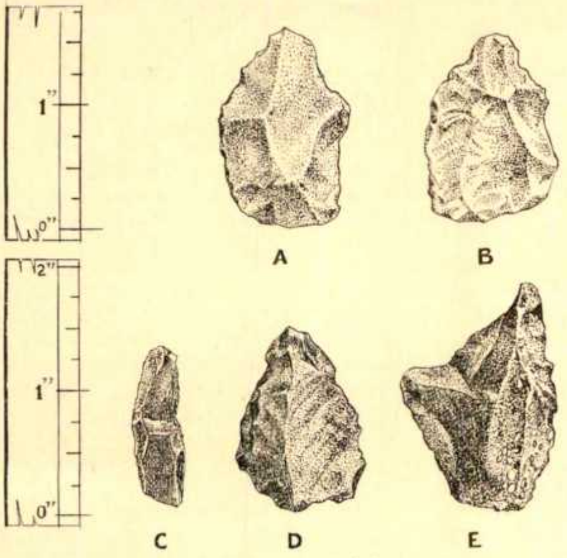

Fig. 2. Scrapers (dorsal view)

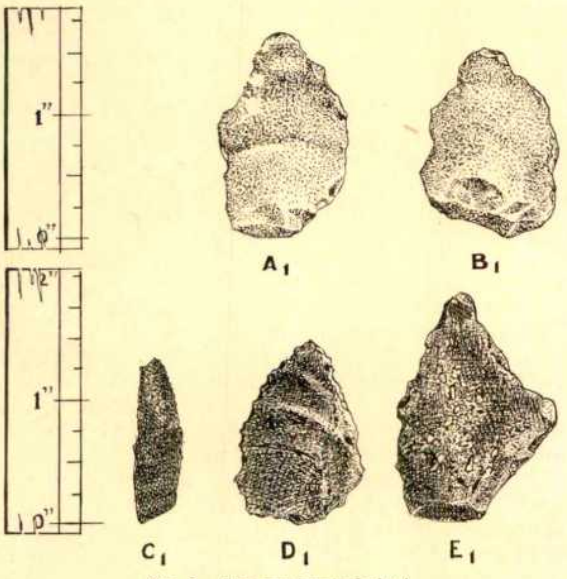

Fig. 3. Scrapers (ventral view)

The specimens of flakes could be of upper Acheulian tools belonging to early Sohan industries[2]. The scrapers show resemblances with early Soan flakes.

To my knowledge there is no record of such palæolithic find hitherto from Khandesh, this being the first find of such type from the Girna River in the Tapti Valley from Khandesh. It is suggested that a systematic survey of the river valleys which has hitherto been neglected be undertaken by archæologists, as it may one day show rich finds since this area was once a Narbada basin during the post-Eocene era.

EDUCATION

" 'Teen-Age' Education in England"

You have, of course, a perfect right to say (*Natur* February 6, 1960) that, in your opinion, the Crowthe Report has made a wrong choice of priorities, bu have you the right to leave out of your article an reference to the conditions that that Report lay down as essential if the age is to be raised ? I calculates the number of extra teachers that will b needed not only to cover the extra year, but als at the same time to reduce over-large classes. I concludes that the task of providing these teacher though formidable, is not beyond the capacity o the country, if it is determined to accept the pla With regard to curriculum, it says that a great variety of courses must be provided, that method of teaching and discipline should be altered so tha the fifteens–sixteens will be treated more like adult and less like schoolchildren, and that staffing ratio should be generous enough to allow "for some adul leadership out of school hours".

Readers of the article in *Nature* who have no read the Report itself would not know that it contemplates these changes before the age can b raised.

With regard to the note by what is called a "stron minority of the Committee", which did not, incidentally, include any of the heads of secondary moder schools, this dealt with the treatment of a sma minority of children. The signatories go out of thei way to state : "To avoid any possibility of misunderstanding, we want to make it clear that thi note does not imply any dissent on our part fro the major recommendation that the school-leavin age should be raised. On the contrary, we feel confident that provision on the lines we have suggeste of a small minority would be held in public opinio to reaffirm the case for keeping the great majorit in school for another year. We certainly regard i ourselves." Apparently, they have not avoide misunderstanding on your part.

It is stated in *Nature* that "No member of th Crowther Committee teaches the lower streams o Modern Schools". This is equivalent to the charg that the three heads of secondary modern and on head of a comprehensive school are ignorant of th conditions which exist in their schools—a grav indictment indeed that would have to be supporte with strong evidence.

Since many States in the United States of Ameri have had a school-leaving age of sixteen for mo than twenty years, and some, one of 17+, wh should we assume that teachers in England are n able to make a sixteen leaving age "socially acceptable" if their counterparts across the Atlantic hav already done so ? Teachers in England have alway responded to the increasing demands that we hav made upon them, and I, for one, refuse to believ that they will fail the nation now, provided that w give them the right conditions for work.

FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

Monday, March 7

University of London (at the Postgraduate Medical School of ndon, Ducane Road, London, W.12), at 4 p.m.—Dr. J. C. White . bnormal Hæmoglobins".*

Royal Geographical Society (at 1 Kensington Gore, London, W.7), at 5 p.m.—Mr A. T. A. Learmonth: "Medical Geography India and Pakistan"

British Society for the Philosophy of Science (in the Joint aff Common Room, University College, Gower Street, London, C.1), at 5 30 p.m.—Mr. Arthur Koestler: "Some Aspects of the ychology of Discovery".

Institution of Electrical Engineers, Electronics and Com- nications Section (at Savoy Place, London, W.C.2), at 5.30 p.m Dr P. N. Butcher: "An Introduction to the Theory of Masers h particular reference to the Travelling-Wave Maser".

Society of Engineers (at the Geological Society, Burlington use, Piccadilly, London, W.1), at 5 30 p.m.—Mr. R Lenoir . rogress of British High Grade Watch Production".

University of London (at King's College, Strand, London, W.C.2), 5 30 p.m —Dr. Bernard O. Phinney (University of California) he Use of Biochemical Genetics in the Study of Gibberellin-con- lled Growth".*

Society of Chemical Industry, London Section (at 14 Bel- ve Square, London, S.W.1), at 6.30 p.m.—Dr. W. Gerrard: "Recent lvances in the Chemistry and Industrial Applications of Hydrido- d Organo-Boron Compounds".

Society of Instrument Technology (at Manson House, 26 Port- ad Place, London, W 1), at 7 p.m —Mr. A. S. Younger, Mr. G. C. rgan and Mr. E. S. Mallett "Data Reduction for Guided Weapon ials at Aberporth".

Tuesday, March 8

University of London (in the Anatomy Theatre, University llege, Gower Street, London, W.C.1), at 1.15 p.m —Prof. W. B. aery: "A Middle Kingdon Fortress in the Sudan".*

University of London (at the London School of Hygiene and opical Medicine, Keppel Street, Gower Street, London, W.C.1), 5 15 p.m.—Dr. F. Sanger: "Amino Acid Sequences in Proteins".*

British Glaciological Society (at Bedford College, Regent's rk, London, N.W.1), at 5 30 p.m.—Annual General Meeting. Mr. Lister. "Drifting Snow".

Institute of Marine Engineers (at the Memorial Building, Mark Lane, London, E.C.3), at 5.30 p.m.—Cdr. R. G. J. Peaver, N.: "Distillation for Marine Purposes".

University of London (at Senate House, Malet Street, London, .C.1), at 5.30 p.m.—Prof. C. G. Hempel (Princeton University): ome Problems in the Logic of Probabilistic Explanation".*

Royal Aeronautical Society (at 4 Hamilton Place, London, .1), at 7 p.m.—Dr J. W. Granville: "Electronic Microcircuits".

Wednesday, March 9

Institute of Fuel (at the Institution of Civil Engineers, Great orge Street, London, S.W.1), at 5.30 p.m.—Mr. J. E. Richards . uclear Power for Marine Propulsion".

Institution of Electrical Engineers, Supply Section (at voy Place, London, W.C.2), at 5 30 p.m.—Dr. B. Salvage and Mr. A. M. Gibbons: "The Impulse Strength of Impregnated-Paper electrics as used in High-Voltage Cables".

University of London (at King's College, Strand, London, W.C.2), 5.30 p.m.—Dr. Bernard O. Phinney (University of California) ibberellins as Native Growth Regulators of Flowering Plants".*

Institute of Information Scientists (at the College of Pre- ptors, 2 Bloomsbury Square, London, W.C.1), at 6.15 p.m.—Prof. lin Cherry: "The Nature of Human Communication".

Society of Chemical Industry. Food Group (joint meeting with e Association of Public Analysts, at 14 Belgrave Square, London, W.1), at 6.15 p m.—Scientific Papers.

Royal Aeronautical Society (at 4 Hamilton Place, London, 1), at 7.30 p.m.—Mr. W. J. Egginton: "The Hovercraft and Its evelopment".

Thursday, March 10

Royal Society (at Burlington House, Piccadilly, London, W.1), 4.30 p m.—Dr. A. L. Hales: "Bernard Price Institute of Geo- ysical Research".

Institution of Electrical Engineers, Utilization Section t Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. J. P. McBreen: ome Considerations in the Application of Power Rectifiers and nvertors".

Physical Society, Acoustics Group (in the Physics Department, perial College, Imperial Institute Road, South Kensington, Lon- n, S.W.7), at 5.30 p.m.—Dr. J. M. Bowsher: "Electronic Music".

University of London (at Senate House, University of London, ndon, W.C.1), at 5 30 p m.—Prof A. Hanau (University of Gott- gen): "Some Results of German Research in Agricultural Marketing d Prices".*

Chemical Society (in the Large Chemistry Lecture Theatre, Imperial College of Science and Technology, South Kensington, London, S.W.7), at 7.30 p.m —Prof. A. R. J. P. Ubbelohde, F.R.S.: "Ionic Crystals and their Melts" (Liversidge Lecture).

Friday, March 11

Royal Aeronautical Society (at the Institution of Mechanical Engineers, 1 Birdcage Walk, Westminster, London, S.W.1), at 9.45 a.m. —Symposium on "Vehicle and Instrumentation Problems in Upper Atmosphere Research". Speakers: Prof. Sir H. S. W. Massey, F.R.S., Mr. J. F. Hazell, Dr R. L F. Boyd, Dr. G. D. Robinson, Mr. H. J. Higgs and Mr. E. C. Cornford.

Physical Society, Low Temperature Group (at the Institute of Physics, 47 Belgrave Square, London, S.W.1), at 10 a.m.—Symposium on "Measurement Techniques (Flow, Pressure, Level, Temperature, etc.)".

Association of Applied Biologists (joint meeting with the British Ecological Society, at the British Museum (Natural History), South Kensington, London, S.W.7), at 10.50 a.m.—Meeting on "Ecological Effects of Crop Production".

Institute of Physics, Non-Destructive Testing Group (at 47 Belgrave Square, London, S.W.1), at 6 p.m.—Dr. R. Jones. "Analysis of Road Constructions".

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Dr. A. E. Werner: "Scientific Techniques in Art and Archæology".

Saturday, March 12

British Mycological Society (in the Botany Department, Birkbeck College, Malet Street, London, W.C.1), from 2.15 p.m. to 5 p.m — Conversazione.

London County Council (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p.m.—Miss A. G C. Grandison: "Collecting Reptiles and Amphibians in the United States of America".*

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned

Assistant Lecturer (with special qualifications or interests in radio astronomy) in Physics—The Registrar, The University, Manchester 13 (March 12).

Assistant Lecturer (with special interest in urban geography) in Geography—The Registrar, Queen Mary College (University of London), Mile End Road, London, E.1 (March 14).

Junior Lecturer (male or female, with an honours degree in chemistry or biochemistry, or A.R.I.C.) in the Department of Chemical Pathology—The Secretary, Westminster Medical School (University of London), Horseferry Road, London, S.W.1 (March 14).

Developmental Physiologist (with a good honours degree and preferably two or more years postgraduate research experience) in the Plant Physiology Unit, Department of Scientific and Industrial Research, Palmerston North, New Zealand, initially to assist in current studies using controlled climate facilities for investigation of the influence of the climatic factors on reproduction in plants of economic importance—The High Commissioner for New Zealand, 415 Strand, London, W.C.2, quoting Ref. No. B.11/21/26 and mentioning *Nature* (March 18).

Assistant Lecturer or Lecturer in Botany—The Secretary, The University, Exeter (March 19).

Imperial Chemical Industries Research Fellows in Chemistry, Physics, Engineering (including Chemical Engineering), Metallurgy, Pharmacology, or related subjects—The Registrar, The University, Sheffield 10 (March 19).

Lecturer in the Department of Sociology—The Registrar, The University, Leicester (March 19).

Research Fellow (engineer, physicist or mathematician) in Production Engineering—The Registrar, The University, Nottingham (March 19).

Lecturer or Assistant Lecturer (preferably with experience or interest in magnetic resonance) in Physics—The Registrar, University College of North Staffordshire, Keele, Staffs (March 21).

Lecturer or Assistant Lecturer (with a good honours degree) in Organic Chemistry—The Registrar, King's College (University of London), Strand, London, W.C.2 (March 21).

Research Assistant (graduate, with botany to the standard of a B.Sc. (General) degree) to the Head of the Department of Botany —The Secretary, Birkbeck College (University of London), Malet Street, London, W.C.1 (March 21).

Assistant Librarian (woman graduate)—The Principal, Royal Holloway College (University of London), Englefield Green, Surrey (March 22).

Demonstrator in the Department of Geology, to act as Curator of Collections—The Registrar, The University, Liverpool, quoting Ref. CV/T (March 25).

Lecturer in Agriculture (Animal Breeding)—The Registrar, King's College (University of Durham), Newcastle upon Tyne 1 (March 25).

Assistant Lecturer in Inorganic Chemistry; and Demonstrators (2) in Inorganic Chemistry—The Registrar, The University, Nottingham (March 26).

Assistant Lecturer in the Department of Chemistry—The Registrar, University College of South Wales and Monmouthshire, Cathays Park, Cardiff (March 26)

Chair of Metallurgy—The Registrar, University College of South Wales and Monmouthshire, Cathays Park, Cardiff (March 26)

Lecturer (with a good honours degree in geology and/or chemistry and research experience in geochemistry) in Geochemistry—The Secretary, The University, 38 North Bailey, Durham (March 26)

Lecturer (with an honours degree or equivalent) in the Department of Fluid Mechanics—The Registrar, The University, Liverpool, quoting Ref. CV/T (March 26).

Senior Scientific Officer (with a first- or second-class honours degree in science or engineering and at least three years postgraduate experience) at the Headquarters of the Department of Scientific and Industrial Research, London, S.W.1, for scientific administrative duties—The Ministry of Labour, Technical and Scientific Register (K), 26 King Street, London, S W.1, quoting E.93/0/A (March 28).

Analytical Chemist (preferably with at least an honours degree with chemistry as a major subject, or a professional diploma of a recognized Chartered Institute) in the Government Analysts Laboratory, Salisbury, Federation of Rhodesia and Nyasaland—The Secretary (R), Rhodesia House, 429 Strand, London, W.C 2 (March 31).

Assistant Lecturer (with an honours degree in botany or agricultural botany, and preferably with research experience and an interest in plant physiology) in Agricultural Botany—The Registrar, The University, Leeds 2 (March 31).

Assistants (2) (with a good honours degree in geography and preferably with a special interest in physical geography and/or cartography) in the Department of Geography—The Secretary, The University, Edinburgh (March 31).

Lecturer in the Department of Pathology—The Secretary, The University, Edinburgh (March 31).

Plant Breeder and Geneticist in the Department of Agronomy (Plant Breeding Section), Waite Agricultural Research Institute, University of Adelaide, Australia, to undertake research on the factors affecting quality and yield in barley and to produce commercial barley varieties—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, March 31).

Research Fellow (physicist, physical chemist or electrical engineer) in Gas Discharges, to work in association with Prof. G. Porter on an investigation of radiation from gas discharges—The Registrar, The University, Sheffield 10 (March 31).

Lecturer (preferably with special qualifications in engineering geology, including hydrology and soil science) in the Department of Geology, University of the Witwatersrand, Johannesburg, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (South Africa, April 15).

Lecturer (graduate in science) in Microbiology—The Secretary, The Queen's University, Belfast (April 30).

Research Fellow in the Department of Chemistry, for a research programme devoted mainly to investigating, in collaboration with Dr. W. P. Doyle, the ultra-violet absorption of thin films of inorganic solids—Prof. T. S. Wheeler, Department of Chemistry, University College, Dublin (May 1).

Assistant or Associate Professor of Mathematics—The Principal, Victoria College, Victoria, B.C., Canada.

Assistant or Associate Professor (with the degree of D Sc. or Ph.D. in zoology from a recognized university and special interests in the physiology of aquatic organisms, particularly fishes) in the Department of Zoology—The Chairman, Department of Zoology, University of Manitoba, Winnipeg 9, Manitoba, Canada.

Biochemist (Basic grade) in the Pathology Laboratory, to assist the Senior Biochemist—The Superintendent, Liverpool Royal Infirmary, Pembroke Place, Liverpool 1.

Regional Trials Officer (graduate in agriculture), for agricultural variety trials conducted by the National Institute of Agricultural Botany at the N.A.A.S. Experimental Husbandry Farm, Terrington St Clement, Norfolk; and an Assistant Trials Officer (preferably with practical experience in crop production), to work at Leeds University Farm, Headley Hall, Yorks—The Secretary, National Institute of Agricultural Botany, Huntingdon Road, Cambridge.

Scientific Officer/Senior Scientific Officer, Physical Chemist or Metallurgist (with a first- or second-class honours degree or equivalent) at the National Physical Laboratory, Teddington, Middlesex, for work in the Metallurgy Division on the use of radioactive isotopes as tracers in metallurgical investigations—The Ministry of Labour, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting Ref. F.648/9A.

Technician (preferably with some knowledge of physics, chemistry and biology, and experience in photography and section cutting) in the Electron Microscope Department—The Secretary, Strangeways Research Laboratory, Wort's Causeway, Cambridge.

PROMOTION OF FUNDAMENTAL RESEARCH

IN recent reports, the National Science Foundation has consistently urged the strengthening of fundamental research, support of which, it has urged, is the key to the progress in science upon which technology depends. It has been widely recognized that the proportion of effort devoted to such research in the United States is inadequate, and the 488 million dollars allocated for that purpose in 1959 or the 494 million dollars in 1960 only represent some 6–7 per cent of the total allocation for research and development. Between 1956 and 1959, it is true, expenditure on fundamental research increased by 143 per cent, and now constitutes almost one third of the total research effort in the United States compared with about one fourth in 1956.

Dr. W. R. Brode, Science Adviser to the Secretary of State, in his presidential address to the American Association for the Advancement of Science on December 28, 1959, remarked on the recent increase in the support of fundamental research and the predicted doubling of such research during the next decade. This, he said, gives a high priority to questions of organization. It is of increasing importance to determine the most appropriate means of arranging for financial support, so as to avoid overlapping and ensure continuity ; equally, the determination of the right priorities, the selection of programmes and decisions as to their relative position, and the distribution of responsibility for their execution. Dr. Brode is obviously deeply concerned as to the way future policy in science is to be determined and executed in the American scene. Even with the vast resources at the disposal of the United States, neither man-power nor material resources are equal to all demands : selection is inevitable, and Dr. Brode is not satisfied that recent changes made by the President, such as the appointment of a Science Adviser and of a Science Advisory Committee, as well as of a Federal Council for Science and Technology, provide all that is required.

Dr. Brode is obviously watching with interest developments in Britain which may follow on Lord Hailsham's appointment as Minister for Science, and particularly the use which may be made of the Advisory Council for Scientific Policy, though he fully appreciates the wide difference between conditions in Great Britain and the United States. It is interesting, nevertheless, in view of the criticism already expressed in Parliament about the arrangements for representation of the Minister for Science in the House of Commons, to find that Dr. Brode is critical of the refusal of the chairman of the newly created Federal Council for Science and Technology to appear before a Congress Committee inquiring into the possible establishment of a Department of Science. The request was refused on the ground that the chairman was a privileged member of the President's staff. Dr. Brode suggests that while the President should continue to have a strong science adviser, it would be better to separate science co-ordination from the President's own office, so that its head could speak before Congress as well as report the findings and recommendations of all his own agencies to the President.

Dr. Brode has put his finger on a vital matter, of which Lord Hailsham has already shown himself to be fully cognizant. It is impossible to take too great care to ensure that what is involved in scientific policy is fully understood at all levels in the organization of government, both in the legislature and in the administration. While he is clearly not fully satisfied that, in the United States, a Department of Science would be an effective means of interpretation and formulation of policy, he firmly urges the establishment of a commission or study group to consider the organization of science and scientific policy in academic, industrial and government fields. Particularly this should examine the re-grouping of the Government's scientific agencies and activities, either under a Department of Science with a National Science Council, a National Science Institute or some other co-ordinated structure. Effective co-ordination would be required between such a re-grouping and those scientific agencies which remained separate, so as to ensure an efficient and comprehensive national science programme in the United States.

With this Dr. Brode suggests that there should be considered a re-alignment of the methods of distributing responsibility for support of fundamental research in educational institutions, possibly through the administration of university grants mainly by a department concerned with fundamental research, rather than by agencies concerned with application. He also suggests some separation of government-sponsored major research institutions from the educational and industrial system, especially of those institutions essentially concerned with applied science, and finally that scientists in government service should be linked with those in the academic field and in industry on a National Science Council. Primarily, he is concerned to see that creative thought, mature judgment and experience are brought to bear on these difficult problems of the formulation of scientific policy and the co-ordination of activities, and also on the attack on scientific and technical problems themselves.

Dr. Brode is undoubtedly right to maintain that thoughtful and penetrating analysis of the problem must precede any decision to change existing institutions and procedures ; and while he is prepared to support drastic action, it is only on the basis of full inquiry. That is known to be Lord Hailsham's attitude, and it is in this context that the papers presented last May at a symposium on Basic

Research in New York and now published by the American Association for the Advancement of Science* are of especial interest. Although fundamental research is only one element involved in the determination of scientific policy, it is probably the essential factor, and the one in which it is most difficult to determine priorities and to exercise co-ordination without detriment to scientific work.

The symposium, which was held at the Rockefeller Institute under the auspices of the U.S. National Academy of Sciences, the American Association and the Alfred P. Sloan Foundation, sought to examine facts concerning the support of basic research in the United States, the reasons why the nation did not give it adequate and suitable support, and ways in which the situation could be improved. Five specific questions were put to the invited participants. Is not the large support of applied research, and still more particularly the massive present support of development, in unhealthy relation to the meagre support for basic research ? Is it not true that industry pays eager lip-service to basic research, but in actual fact does not give adequate support to basic research, either within industry or elsewhere ? Has either industry or the Government learned how to protect basic research from the insistent demands of applied research and development ? Are not universities so deeply invaded by the demands for solving immediate problems, and by the temptation of income for so doing, that there are too few competent scholars pondering problems simply because it interests them to do so, so that scholars in the universities of the United States may have lost the manœuvring room for their continuing re-analysis of the universe ? Has it been effectively accepted that the spirit of basic research is an essential ingredient of the educational process—and that this fact should affect educational procedures at all levels ?

None of these questions can be dismissed as irrelevant in a British context, and although the answers which might be given may differ considerably, especially in detail, it is a tribute to the quality of the symposium that the addresses reproduced in this volume should bear so closely on current problems of the organization of the research effort in Britain which the Advisory Council on Scientific Policy must now be considering and which impinge closely on the expansion of universities and of technological education. That might indeed be expected from the eminence of the contributors, which include Dr. J. R. Oppenheimer, Dr. A. T. Waterman, Dr. L. A. DuBridge, Dr. J. R. Killian, Dr. C. H. Greenewalt, Dr. A. V. Astin, Dr. J. B. Fish and Dr. M. A. Tuve, and it is noteworthy that in directing the attention of the symposium at the start to the need for new knowledge, Dr. Oppenheimer was not content merely to urge that getting new knowledge was an ennobling as well as a useful activity. Beyond its character as a human, creative activity, he pointed to the wide field of study which man's institutions, his whole society now present—underlining, as it were, the basic contention in Dr. Brode's address already noted.

Dr. W. O. Baker, discussing the paradox of choice for the research worker, followed a very similar line suggesting that it is time we began to consider what specific skills as well as ideals are needed for the advancement of civilization. If a fraction of the effort that has been given to the acquisition of physical skills were given to the practice on proper levels of mathematical reasoning and exercise, we might prepare that small but necessary group which would interpret, as well as the essential group which would create, conceptual science to come. Dr. Baker quoted Dr. Warren Weaver's remark that "our society has not yet evolved a satisfactory way of fostering creative scholarship" in illustrating the potential contribution of scientific method in developing the appropriate institutions for both fundamental and applied research.

The clearest picture of the actual position of fundamental research in the United States was presented by Dr. A. T. Waterman, who, taking the figures for 1956–57, when some 7 per cent of the 9,000 million dollars expended in the United States on research and development went to basic research, said that of 300,000 full-time engineers and scientists estimated as engaged in research and development 27,000 were on fundamental research, 14,000 being in educational and other non-profit institutions, 9,000 in industry, and 4,000 in the Federal Government. Recognizing the vital importance of the universities in this field and the difficulties arising in regard to finance, Dr. Waterman concluded that the evidence shows that fundamental research requires stronger support at colleges and universities ; provision for renovation of research laboratories and for up-to-date scientific equipment presents outstanding problems. Clearly, the selection of problems and determination of priorities present very similar problems in the United States and in Britain, and Dr. Waterman seems more confident than Dr. Brode that the new organization in the United States is appropriate to the conditions there. He concedes, however, the importance of the right choice of men, and this is the factor that other participants repeatedly stressed. Dr. Killian remarked that a report recently presented to the new Federal Council for Science and Technology had cited highly trained scientific man-power as constituting the real limit to the development of materials research, and urged the need not simply for more fundamental research but also for more men capable of creative contributions. Dr. C. H. Greenewalt, who claimed that the du Pont de Nemours Company is now spending more than 15 million dollars a year on fundamental research, urged a substantial increase in unrestricted funds for the universities, provided both by industry and government, but based not upon projects but on men—not upon desired objectives but upon creative talent. Dr. M. A. Tuve, of the Carnegie Institution of Washington, commented that the United States has not had much success, as a nation, in encouraging quietly creative scholarship and intensely personal activity in research; and he suggested that the support of fundamental research is the support of ideas. This always means support of a creative investigator, and he proposed that public funds should be used to pay the salary for the remainder of his working life of a gifted research worker, who had clearly established by the age of thirty or thirty-five his creative ability.

---

* Symposium on Basic Research. Edited by Dael Wolfle. (Sponsored by the National Academy of Sciences, the American Association for the Advancement of Science, and the Alfred P. Sloan Foundation, and presented at the Rockefeller Institute, May 14–16, 1959, New York City.) Pp. xx+308. (Washington, D.C.: American Association for the Advancement of Science ; London : Bailey Bros. and Swinfen, Ltd., 1959.) 27s.

Dr. Tuve visualized the creation in one decade of a body of some 500 or 600 outstanding investigators by the allocation of perhaps 40–60 million dollars a year in creating research professors or scholars of this type; and although in summarizing the symposium, Dr. D. Wolfle recognized that there are both administrative and financial difficulties, he pointed out that there are already precedents in the research professors at universities and the permanent staff of private research institutions. The participants of the symposium, in fact, recommended wider use of research professorships or similar posts as a means of furthering fundamental research.

The other recommendation which came from the symposium was that universities must always be expected to carry the largest responsibility for basic research, and that accordingly they should be provided with larger unrestricted funds. There was also repeated insistence that a larger proportion of the present Federal research and development budget should be available for the universities on an unrestricted basis. Only with a sufficiency of such funds can the universities adequately discharge their continuing responsibilities for teaching and creative scholarship, and maintain a reasonable balance between teaching and research and among the various fields of scholarship. It was equally plain that those present entertained the same distrust of project grants as universities in Britain have of sponsored research and earmarked grants. The vital factor is to free creative scholarship from whatever limits its efforts. It is essential to concentrate on intellectual quality, and while the importance of freedom to investigate and to publish was generally recognized, there was less disposition to concede that the difference between State-owned and privately owned institutions is always as great as is commonly maintained. Dr. DuBridge, in fact, was deeply sceptical of scientists as administrators, particularly in government institutions and when controlling the activities of other scientists through the administration of research grants.

This is not to challenge the freedom of the scientist to decide the conduct of his own research or the choice of his programme: it is rather to challenge the validity of attempting to apply cost-accounting practices too closely, and to stress the need to maintain the appropriate intellectual environment and the conditions of service under which basic research is most effectively pursued. That, as Dr. Fish pointed out, involves a certain freedom in the choice of problems, subject to the criterion of relevance, as well as freedom to carry a project to the point of demonstrating the merit of an idea and then to drop the study and follow the next good idea. These are not, however, inherent rights of individuals, and Dr. Tuve made it clear that the Carnegie Institution of Washington interprets the support of ideas always as the support of a man. Dr. DuBridge saw the essential problem as that of attracting sufficient of the nation's ablest minds to the universities and giving them full encouragement and support in pursuing whatever lines of inquiry interested them.

Admittedly that is a difficult challenge to meet, especially with the mounting costs of equipment and assistance in many fields of inquiry, and even though, in comparative costs, expenditure on academic fundamental research may not, in the United States, be more than twice what it was before the War. Thus the expenditure of fully 800 million dollars, which Mr. R. E. Wilson is inclined to regard as the current total expenditure on basic research in the United States, may be inadequate; and the determination of priorities and the establishment and maintenance of appropriate conditions are unlikely ever to be other than major pre-occupations in the United States as in Britain. The symposium threw up few, if any, novel ideas; but it demonstrated the way in which fundamental and applied research are interlocked and are also related to education and to professional training. The universities and the independent research institutions as well as industry and government institutions have their contribution to make, but in determining the structure in which all these activities are most appropriately fostered and co-ordinated the first consideration should be the promotion of excellence, the encouragement of able investigators and their sustained and adequate support with finance, equipment and assistance.

GALILEO AND EULER AS POPULAR EXPOSITORS

Discorsi e Dimostrazioni Matematiche Intorno a Due Nuove Scienze

Di Galileo Galilei. A Cura di Adriano Carugo e Ludovico Geymonat. (Classici della Scienza, 1.) Pp. xxv+887. (Torino: Paolo Boringhieri, 1958.) 7,000 lire.

Lettere a Una Principessa Tedesca

Di Leonhard Euler. A Cura di Gianfranco Cantelli. (Classici della Scienza, 2.) Pp. xxvi+960. (Torino: Paolo Boringhieri, 1958.) 8,000 lire.

THESE two volumes provide, among many other things, an excellent opportunity for comparing Galileo and Euler as popular expositors, albeit at greatly different levels. Galileo's "Discorsi" first appeared in 1638; published at Leyden, in order to evade the ban imposed by the Inquisition, they incorporate material on which the author had been meditating for a long time, and which is so varied that neither Galileo nor any of his friends succeeded in finding a suitable title for it. Thus the first of the four discussions into which the main portion of the book is divided actually begins with one of the principal themes—the strength of materials—but soon passes to an examination of the concept of continuity and thence to an essay on transfinite numbers.

The dialogue form in which the book is cast lends itself to, and indeed encourages, this sort of discursiveness. Galileo has distributed his exposition and commentary among three speakers: two of these, Salviati and Sagredo, are former pupils, while the third, Simplicio, is an imaginary personage. It is Salviati's function to enunciate and expound; Simplicio, on the other hand, represents the opposition; and Sagredo, an intelligent layman, not only provides the pretext for a further explanation, in simpler terms, of the author's ideas, but also is used to express concepts for which Galileo did not wish to accept full responsibility.

To obtain an adequate notion of the book's contents, one would have to quote Galileo's own index. The second main theme is the theory of accelerated motion, with application to projectiles; but intertwined with this is a considerable amount of applied mathematics as well as many pioneer results in the integral calculus.

The editors have carried out their task with great skill and devotion; the text, which runs to nearly 600 pages, is accompanied by 300 pages of notes. Moreover, those demonstrations which originally appeared in Latin are here reproduced with parallel translations in Italian. With regard to style, Galileo's own limpid prose furnishes a model which, unfortunately, few of his compatriots have seen fit to adopt.

Euler's "Letters to a German Princess" are a classic of a quite different kind; composed during 1760–62, they were addressed to his pupil, daughter of a Margrave, from whom he was separated by the vicissitudes of war. The letters were first published in French, at St. Petersburg, achieving an immediate and extraordinary success. Translations into most European languages soon followed, and numerous reprints (eight in Paris and six in New York) bore witness to the popularity which the work enjoyed for nearly a century, long after it was largely outmoded: suffice it to remark that the book contains an attack on Leibniz's theory of monads and a defence of Newton as against Descartes—both highly topical matters at the time when Euler wrote.

The reasons for this popularity are very clear. To begin with, the letters give a detailed description of almost the whole of elementary mathematics and physics, including astronomy, as Euler understood them. This part of the work is a masterpiece of exposition; it includes accounts of what were then recent results, such as the first experiments with electricity and the determination of longitude at sea (incidentally, for contributions to this problem Euler himself received a prize of £3,000 from the British Parliament). As a popular scientific encyclopædia the book would be difficult to surpass. But there is obviously another cause for Euler's success: the purely scientific information is coupled with instruction in formal logic, philosophy and religion, designed to combat the spirit of the Enlightenment. In this field Euler was an amateur, and an ill-informed one at that; he made himself ridiculous to his contemporaries.

A perplexing question raised by the "Letters" (234 in all) is the intellectual status of their recipient; one is forced to conclude that she was ignorant of almost everything—there are even lessons in elementary arithmetic—but deemed capable of absorbing anything whatever.

The present version, based on the second French edition, reads very well. Both the Galileo and the Euler are handsome books, and should be in every scientific library.

L. Roth

THE LUNAR SURFACE

Strange World of the Moon

An Enquiry into Lunar Physics. By V. A. Firsoff. Pp. x+226+12 plates. (London: Hutchinson and Co. (Publishers), Ltd., 1959.) 25*s*. net.

PERSISTENT observers of the Moon, many of them amateurs with small instruments and little scientific training, have often reported changes of various kinds in the appearance of the lunar surface; these have tended to be met with scepticism by most professional astronomers; but until the last year or two very few professionals have spent much time on lunar observations, and there is thus a considerable chance that genuine phenomena have been missed. The present book, which attempts to interpret changes seen by the author and other observers in terms of known physical and chemical laws, is timely in view of the indisputable observation by N. A. Kozyrev of a short-lived bright cloud of dust and of C_2 and C_3 gas near Alphonsus in November 1958, and in view of the increased interest in the Moon resulting from the new facilities offered by space rockets.

The author points out that the Moon's orbital plane is inclined at only 5° to the ecliptic, which, together with its large size, suggests that it is a captured planet rather than an off-shoot of the condensing proto-Earth. This leads him to speculate that, as a result of planetary perturbations and tidal action, the Moon may have approached and receded from the Earth several times, each approach having led to distinct mountain-building fault systems in both bodies; but an elementary mathematical treatment given in an appendix shows that rather extreme conditions must be assumed. He rejects the impact theory for the origin of craters in favour of 'lunavoes' (a term coined by J. E. Spurr), which are essentially broken bubbles of gas bursting out from a contracting surface; wrinkle ridges on certain maria are treated as evidence for a viscous liquid filler, rather than dust. Mr. Firsoff attributes ray systems to erosion by running water, fed from large deposits of ice accumulated below the spongy surface rocks, and he suggests that the maria, also, are filled by impure ice. The main changes observed consist of the occasional disappearance and creation of craters, puffs of dark and bright dust or vapour, and local changes in brightness and colour at sunrise, many examples of which have been studied by Firsoff himself with the aid of filters, and which he attributes to the evaporation of snow (or possibly carbon dioxide and other volatile solids). This leads on to a discussion of the lunar climate and atmosphere in which it is shown that, in view of Lyman Spitzer's work on the terrestrial atmosphere and of the presence of appreciable amounts of argon resulting from the decay of potassium, the old idea that all water vapour would have escaped may be quite untrue. Firsoff concludes that the lunar surface, or at least subsurface regions, can be the seat of extensive climatic and seasonal changes, and even of rudimentary forms of life.

The ideas presented in the book are interesting and highly provocative, and the significance of much of the experimental and theoretical work that has been done is discussed in considerable detail, with helpful technical details in the appendixes. Basically, however, the author's arguments only show that his ideas are barely possible; he has certainly not shown that they are at all likely. In particular, the idea that water is present on the lunar surface is highly implausible, not because of escape, but because of the presence of solar ultra-violet radiation, which is known to dissociate water vapour into hydrogen and oxygen in the upper atmosphere of the Earth; the resulting hydrogen would certainly escape from the Moon. Again, the discussion of craters and mountains fails to do justice to the very strong and detailed case for meteorite impact that has been made by R. B. Baldwin and T. Gold. The value of the book thus lies more in its description of observations and in the questions it provokes than in the answers that it suggests. B. E. J. Pagel

SECONDARY MODERN SCHOOLS

Your Secondary Modern Schools

An Account of Their Work in the Late 1950's. By J. Vincent Chapman. Pp. 298. (London: The College of Preceptors, 1959.) 12*s*. 6*d*. net.

Although many opinions are given about the encouraging successes or the utter inadequacies of the secondary modern school, these are often coloured by information gathered from one or two areas only. As a result many educationists, including heads and assistants from secondary modern schools themselves, have a distorted picture of the general position in the 3,500 secondary modern schools scattered throughout Great Britain.

Benefiting by the award of the Doreck-Isbister Fellowship by the College of Preceptors, J. V. Chapman has been in touch with about half the total number of schools and here records the information and impressions he has gained from his face-to-face and written inquiries. Chapman sought information under three headings. First, on the amount of time allowed for a certain subject on the school's timetable; secondly, the general syllabus of work; and thirdly, the titles of books being used in the main subjects. From this he has built up a record which, on the whole, is one of good work being done in discouraging circumstances, but which, given more buildings and adequate staffing, could be considerably improved.

The demands on school headmasters and headmistresses are heavy but cheerfully accepted. Her Majesty's inspectors have to be accommodated; parent-teachers' associations have to be stimulated; medical inspections have to be arranged; reports for parents and employers have to be written; school journeys need organizing. These and many extramural activities throw considerable strain on the school staff; but, even with school milk and school meals, the masters and mistresses carry on with the main job of providing an all-round general education for pupils of widely varying intellectual levels.

Despite the explosive outbursts of the 'Now-when-I-was-a-boy' school, English is well taught in the 3½ hr. a week which is allotted to it in the average school. The influence of good teaching, however, is soon minimized in homes which culturally know little more than the 'Daily Distress' and Channel 9. About the same time is allowed for mathematics; but here the quality of work done depends quite simply on whether or not the school has managed to capture and retain a competent teacher.

Science teaching is, by-and-large, non-existent. Apart from the odd school with a proud record, the story is one of laboratories waiting for teachers or of teachers, despairing of facilities which take a long time to come, leaving to go elsewhere. It is a sad reflexion that the author of such a book has to fill up a chapter heading with 'Science, including Gardening'. Subjects like history, geography and crafts are well covered although many more schools would teach metalwork if they had the facilities. Physical education is a credit to the schools; a beginning has been made with French and commercial subjects. Domestic science and needlework are given considerable attention in girls' schools, while, in some schools, music is treated with such enthusiasm that "the bugbear of the breaking voice is overcome simply by denying that it exists".

The findings in this factual account of what is going on in secondary modern schools to-day inevitably leads one to question the wisdom of the Crowther Committee in recommending that the school leaving age be raised compulsorily for all children to sixteen. Before this is done the nation should repay the considerable debt to the worthy men and women in secondary modern schools who have managed to make such good bricks with so little straw. Any money available for education should be spent on better buildings, providing adequate staff, and seeing that no longer should some headmasters be able to write that in each year they are allowed to spend a total of 9*s*. 6*d*. on books for each child. Two packets of cigarettes a year! T. H. Hawkins

"B.D.S." PHYSIOLOGY AND BIOCHEMISTRY

Textbook of Physiology and Biochemistry

By Prof. George H. Bell, Prof. J. Norman Davidson and Prof. Harold Scarborough. Fourth edition. Pp. xi+1065. (Edinburgh and London: E. and S. Livingstone, Ltd., 1959.) 63*s*. net.

This text-book, like an old friend, is often referred to by initials rather than by name, and to many students, even dental students, "B.D.S." probably first suggests this book rather than a degree. This new edition comes only three years after the last one—an indication of the popularity of the book—and it is good to see that Spanish and Italian editions are now being published. It would scarcely be expected that many major changes would have been made after so short a time, and the chapter headings are the same as before, except that a chapter on glycolysis and the citric acid cycle replaces one which summarized liver function. Many changes, though, have been made within the chapters to bring the text and bibliographies up to date. The chemical structures are, in many cases, more clearly set out, and there are some new illustrations, including an attractive coloured one of protein chains. This book has always been notable for its generous provision of illustrations, and students appreciate the way in which so much of the experimental material is presented graphically so that it can be more quickly grasped and more easily remembered. The experimental evidence for the facts is given so far as possible, and this is one of the most valuable qualities of the book.

I was disappointed not to find any discussion of the interesting genetic and biochemical features of abnormal hæmoglobins such as the one associated with sickle cell anæmia, nor anything about the trial of diets low in phenylalanine as a possible means of preventing brain damage in infants suffering from phenylketonuria. In a book used so much by medical students some of the over-generous space given up to structural formulæ of, say, the porphyrins might be better used in some such way. This is not a plea for a larger volume: indeed, the authors are to be congratulated on having made this edition slightly smaller than the one before—something that rarely happens in a new edition. It is greatly to be hoped that they will maintain their enthusiasm for keeping this excellent text-book up to date. If at the same time they find it possible to continue the pruning process, so much the better; future generations of medical, dental and science students will be the more grateful to them.

D. C. Harrison

METEOROLOGY FOR GEOGRAPHERS

Weather and Climate

By Dr. Clarence E. Koeppe and Dr. George C. de Long. Pp. viii+341. (London: McGraw-Hill Publishing Company, Ltd., 1958.) 58s.

THE authors of this book are American professors of geography. They state in the preface that it is intended primarily for students of geography needing a more detailed and scientific knowledge of weather and climate than is provided in a first geography course, but lacking the knowledge of physics and mathematics required for a standard course in technical meteorology, and for students interested in a liberal arts training without the intention of becoming professional geographers or meteorologists.

The first eleven chapters set out to give in 144 pages an outline of physical and dynamical meteorology without using any mathematics or assuming any knowledge of physics. This is a very difficult task in which the authors have not succeeded. The sequence of ideas is loose, the essential physical principles are not stated or not clearly brought out, and in places the text would certainly be misleading or puzzling to readers of the type to whom it is directed. What, for example, is to be made of the following sentence about the relation of winds to the contours on the 500 mb. chart, "Winds tend to blow parallel with the contours and thus toward the depressions, which is in accord with the principle, already stated several times, that although air moves down the isobaric slope, it can move at a deflection of as much as 90 degrees to the slope"?

The second part, of 190 pages, on climate is much better though not entirely free from error. The Earth's climates and corresponding types of vegetation are described in fair detail in terms of the Koppen-Geiger classification of them. An attractive feature is the photographs of typical landscapes in the various climatic types. Most illustrations, including cloud forms, are well reproduced, but what would the late G. A. Clarke of Aberdeen, Scotland, have said to the 'acknowledgments' (to the U.S. Weather Bureau) for the two of his photographs in Figs. 11–2 and 11–3 or the quality of reproduction of the first?

The book cannot on the whole be recommended.

G. A. Bull

ANIMAL MYCOSES

Fungal Diseases of Animals

By Dr. G. C. Ainsworth and P. K. C. Austwick. (Review Series No. 6 of the Commonwealth Bureau of Animal Health.) Pp. xii+148+12 plates. (Farnham Royal: Commonwealth Agricultural Bureaux, 1959.) 20s.

CLINICAL mycology has never been a favourite subject among pathologists. Lecturers promise to deal with it at the end of the course, time permitting; the hospital bacteriologist unwillingly allows a few mould cultures to lie at the end of the bench until one day, angered by the inexplicable appearance of a green flannel-jacket of *Penicillium* on some precious batch of media, he rises up and indignantly consigns them to the autoclave. Identifying and classifying moulds is a formidable enough task to account for much of the unpopularity of the subject; another cogent factor is the shortage of reference works. Conant's "Manual of Clinical Mycology", published in 1954, relieved the situation as regards fungal diseases of man, and Ainsworth and Austwick have now attempted to codify current knowledge of veterinary mycology. The literature is extremely well covered, and for this reason the book should be of great value to research workers and teachers; undergraduate students (for whom it is said to be partly intended) will probably find much of the detail confusing, and if too little space is devoted to clinical matters for the book to have any great appeal for the practitioner, this is perhaps understandable since neither author is a veterinarian.

It is the contrast between the general ætiological patterns of animal and human mycoses that medical workers and biologists will find most fascinating. The key to the problem seems to be the greater exposure of domestic animals to unhygienic conditions, dirt, dust and spoiled or partly decomposing foodstuffs—in short, to infection with normally saprophytic fungi. Thus aspergillosis of chicks may follow inhalation of dust from mouldy grains or litter; bovine mycotic abortion is associated with the winter feeding of spore-containing hay, mycotic mastitis with the feeding of stale brewers' grains and mould toxicoses with damaged maize and other cereals; in sheep the multiplication of saprophytic Actinomycetes in rain-soaked and rotting wool leads to mycotic dermatitis, and soil or mud contamination of the limbs is a major factor in the ætiology of cattle farcy, a form of nocardiosis recalling in many ways Madura foot in the human subject. This is a theme which might well be elaborated in a later book, and who better than Dr. Ainsworth with his unique knowledge of both medical and veterinary mycology to do so?

J. E. Smith

Beetles of the British Isles

By E. F. Linssen. First Series: The Superfamilies Caraboidea, Palpicornia, Staphylinoidea and Diversicornia. Pp. 300+39 plates. Second Series: The Superfamilies Clavicornia, Heteromera, Lamellicornia, Phytophaga and Rhynchophora, and including the Strepsiptera. Pp. 295+87 plates. (Wayside and Woodland Series). (London and New York: Frederick Warne and Co. Ltd., 1959.) 60*s*. net the set.

THE aim of the "Wayside and Woodland" series is to enable naturalists and others to identify animals and plants in the field, chiefly by comparing their specimens with good-quality figures. In the present work the figures of adults are taken mainly from Fowler (1887–1891) and those of larvæ (as usual) from Schiodte (1861–1883). The latter have been adapted by Mr. A. F. Stuart, who is also responsible for the text-figures and the colouring of the plates. His work, original or adapted, is excellent. Of the 126 plates, 64 are coloured.

Many beetles can only be examined satisfactorily under a microscope, and in this work fine structural characters are given so that closer and more reliable determinations can be made than by using figures alone. There are keys to the families of some major groups. The system of classification adopted is that of Kloet and Hincks (1945). A most useful table is given in both volumes showing the superfamilies of Polyphaga recognized by various authors (1 : 140–141 and 2 : 16–17).

A work of this kind must inevitably take the form of a catalogue of species, with notes, and the author should be able to express himself clearly, concisely and authoritatively. Unfortunately, Mr. Linssen's style is cumbrous and many of his statements are inaccurate or obscure. Particularly deplorable is the large number of misspellings of scientific names which cannot fail to confuse the amateur, especially as genuine obsolete spellings are often given.

R. T. THOMPSON

From Ape to Angel

An Informal History of Social Anthropology. By H. R. Hays. Pp. 461+32 plates. (London: Methuen and Co., Ltd., 1959.) 36*s*. net.

BOOKS to popularize science may take many forms. Very attractive are those where some great man of science takes a recent discovery and translates it into language which can be understood by those whose knowledge of science is limited, but who still have inquiring minds. Equally valuable is the general interpreter, a man who appreciates the interest of the general public in a particular aspect of science at a given time, and distils knowledge from a wide variety of sources and presents it in an attractive and readily assimilable form. Because these works contain little that is wholly new and, for the sake of simpleness, sometimes put considerable strain on veracity, they are often dismissed with contemptuous references to 'pot-boiling'. Hays's popular narrative of man as a social animal, including accounts of his primitive behaviour, could be put in the latter category. Yet here, to match up with the considerable interest in the lives of primitive peoples which has been evoked by television, is a book which may well develop into a best-seller. To describe the extraordinary ethical, religious and marital customs of primitive peoples, Hays provides a short biography of the lives of famous pioneer anthropologists such as Henry Shoolcraft, Westermarck, Sir James Frazer, Franz Boas, Bronislaw Malinowski and others. The result has been the production of an informal history of social anthropology which is attractive and informative and which does the author credit for the assiduous way he has collected his information and put it together. "From Ape to Angel" has deservedly won recommendation from the Book Society.

T. H. HAWKINS

The Thyroid Hormones

By Dr. Rosalind Pitt-Rivers and Jamshed R. Tata. With a Chapter on Diseases of the Thyroid by W. R. Trotter. (International Series of Monographs on Pure and Applied Biology. Division: Biochemistry, Vol. 1.) Pp. xiii+247. (London and New York: Pergamon Press, 1959.) 50*s*. net.

A BOOK by two such authorities on research into the thyroid gland could scarcely fail to be useful. The authors say that their aim is to unfold the story of the thyroid hormones and to discover which hypotheses concerning their biosynthesis, mode of action, and the ætiology of thyroid disorders, have received experimental support. They also have tried to provide research workers in the field of thyroid physiology and biochemistry with as many references to the recent literature as possible.

The unexpected appearance of tri-iodothyronine on the scene in 1952, in which Dr. Pitt-Rivers herself played a leading part, has led to much new thinking about thyroid hormones. We are still without a finally accepted view about the nature of thyroid hormones and their mechanism of action, but the present book sets out as much as can be reasonably concluded at the present time. More information about the actual amounts of the different thyroid hormones found in blood and tissues under physiological conditions might have been expected, but undoubtedly much checking and re-checking must be done before final conclusions are drawn. The authors have clearly succeeded in their formulated aims in writing this book.

F. G. YOUNG

Dana's Manual of Mineralogy

Revised by Prof. Cornelius S. Hurlbut, jun. Seventeenth edition. Pp. xii+609. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1959.) 78*s*. net.

JAMES DWIGHT DANA'S classic "System of Mineralogy" has stood the test of time, so also has his "Manual of Mineralogy", which has now reached its seventeenth edition. The first edition of the "Manual" appeared in 1848; since then many revisions and editions have appeared, the last being in 1952. The latest revision was undertaken by Cornelius S. Hurlbut, jun., professor of mineralogy in Harvard University. It introduces the broad use of the crystal-chemical approach, and many of the chapters have been expanded in this light. The chapter on "Crystal Systems" now includes discussions of the stereographic projection, the thirty-two crystal classes, calculation of axial ratios and X-ray crystallography. This new approach enables the properties of minerals to be treated through fundamental structures and chemical consideration. It is hoped that if future revisions are made care will be taken not to resolve the "Manual" into a form indistinguishable from the "System of Mineralogy". It is better that the "Manual" maintains its original purpose, for students, amateur collectors and mining geologists.

INCREASES IN THE LOCAL GAMMA-RAY BACKGROUND DUE TO NUCLEAR BOMB FALL-OUT

By J. VENNART

Radiological Protection Service, Belmont, Sutton, Surrey

IN 1956, prior to the large-scale testing of thermonuclear weapons, Spiers and Griffith[1] and I[2] made measurements of the local gamma-ray background in Leeds and Aberdeen, and in Belmont and London respectively. A noteworthy feature of the measurements was that, due to the low radioactivity of the underlying chalk of the North Downs, the local gamma-ray background to which man is exposed in Belmont was about 60 per cent of that in Leeds. It is now known that this is principally due to the small amount of potassium in chalk (about 20 parts per million compared with 5 per cent in common building materials), giving a correspondingly low concentration of the naturally occurring radioisotope potassium-40. In addition, the contribution from the other principal naturally occurring radioelements, thorium and uranium, is about ten times less than that in common building materials[3].

These facts have had important repercussions with regard to the design of low-background laboratories within the chalk at Belmont, which are used for the measurement of low levels of radioactivity in humans[4] and in food[5]. We are therefore concerned about any increase in the local gamma-ray background of our environment, and accordingly in April 1958, shortly after our low-background laboratory was completed, I initiated regular checks out of doors at the Belmont Hospital and have continued these to the present day. In addition to these measurements I have also on one or two occasions repeated the measurements reported for 1956 inside and outside a dwelling house at Belmont and at other spots in and around the Hospital. The results show that during the period of the measurements, the local gamma-ray background out of doors increased steadily and reached, in April 1959, a maximum which was about twice that in 1956. In recent months there has been a spectacular fall, presumably due to the cessation of nuclear testing, and at the present time the local gamma-ray background out of doors is barely significantly different from that measured in 1956. As regards the local gamma-ray background inside buildings, measurements made on two occasions indicated that the increase varied considerably with the shielding effect of walls but might be in the order 50 per cent of that reported out of doors. I am reporting these measurements now so that a comparison may be made with others reported recently by Peirson and Salmon[6] for various parts of Britain and by Spiers[7] for Leeds, and also so that the magnitude of this increase in relation to man's previous radiation history may be discussed.

The measurements were made, as they were in the early experiments[2], with two counters G.10 lead and G.10 carbon enclosed in brass cases 1½ in. in diameter and 1·2 mm. thick. The same G.10 carbon counter was used for the whole period, including the 1956 measurements, whereas, due to breakages, it was necessary to use four different G.10 lead counters. However, these had previously been calibrated against a radium standard and their sensitivities were the same within 2 per cent. All the counters were checked regularly for constancy of response with a weak radium source. The residual counter response to cosmic radiation and counter contamination was determined by shielding experiments out of doors and also within the 9-in. thick steel enclosure used by Spiers at Leeds. The value obtained was approximately 40 counts/min. for either type of counter. As described in the earlier paper, the ratio of the counting rates due to local gamma-rays from the two counters at a given site is a measure of the relative proportions of primary radiation and scattered radiation in the local gamma-ray background. This ratio has remained substantially constant at about 2·1 for all sites throughout the whole series of measurements. It may then be shown[2] that the local gamma-ray dose-rate in m.rads/yr. is given very approximately by (1) counting rate due to local gamma-rays in the G.10 lead counter multiplied by 0·9, (2) counting rate due to local gamma-rays in the G.10 carbon counter multiplied by 1·9.

Fig. 1 shows the net counting rate out of doors due to local gamma-rays (left-hand ordinate), for the G.10 lead counter placed about 3 in. above closely mown grass outside the low-background laboratory. Apart from December 1959, when only two measurements were taken, about forty individual measurements were made each month; for any single measurement the standard deviation of the counting was about 2·5 counts/min. The mean value for any day was found from three to four separate measurements of the background; and the graph shows, for each month, the mean and the standard deviation of the distribution of these daily mean values. An interesting feature of the measurements was the increase in counting rate which followed heavy rain. For example, in August 1958, during a heavy thunderstorm, the counting rate due to local gamma-rays rose to 85 counts/min., but within 4 hr. of the rain ceasing this had fallen to about 42 counts/min. A large fraction of the difference, 43 counts/min., may therefore be attributed to the gamma-emitting decay products of the naturally occurring gas radon which decay with an effective half-period of the order of half an hour. No measurements which were taken during or immediately following heavy rain have been included in the graph.

The graph also shows (right-hand ordinate) the dose-rate in m.rads/yr. using the calibration factor given above. Although these values represent the dose-rate at 3 in. from the ground, other measurements made at a height of 2 ft. gave similar values. This result is in accord with the well-known fact that the local gamma-ray dose-rate is independent of height above the surface of the Earth, provided this does not exceed a few metres[8]. Accordingly, the dose-rate values shown on the graph are, to a close approximation, the local gamma-ray dose-rates to which man has been exposed at the site.

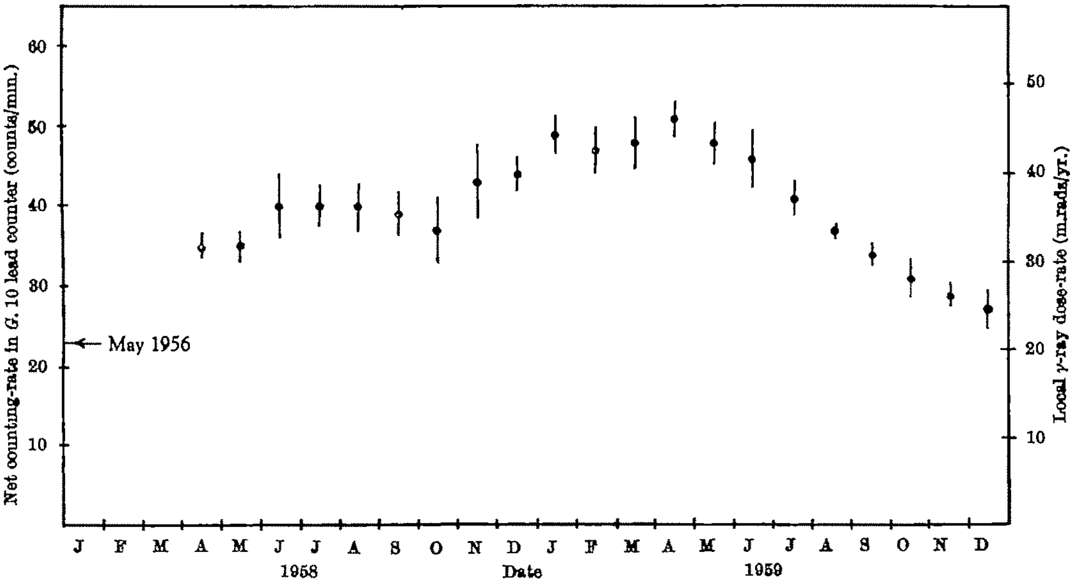

Fig. 1. Local gamma-ray background out-of-doors at Belmont, Surrey

Measurements were also made with the carbon counter on five occasions throughout the series, and the dose-rate so determined agreed with that obtained from the *G*.10 lead counter to better than 5 per cent.

It will be seen from the graph that in April 1958, when the present series of measurements began, the counting rate due to local gamma-rays was 12 counts/min. greater than the value, 23 counts/min., obtained in May 1956 at the same site. Measurements at two other sites, one over a tarmac courtyard within the Belmont Hospital grounds and one over the garden of a house in Belmont, at which measurements had been made in early 1956, showed similar increases in counting rate, namely 15 and 11 counts/min. respectively. It is of interest to note that the increase in counting rate was about the same over closely mown grass, cultivated garden and tarmac. This evidence, coupled with that of Spiers[7], would imply that it may be over-optimistic to use a protection factor of 3, as was suggested in Appendix *M* to the Medical Research Council's report of 1956 [9], to take account of fall-out material which is washed into drains or otherwise removed from the topmost layer of the surface of the Earth. From April 1958 the counting rate continued to increase steadily, apart from a fall in October 1958, to a maximum in April 1959 which was more than twice the 1956 value. The corresponding dose-rate at this peak period was about 25 m.rads/yr. more than in 1956. By December 1959 the counting rate due to local gamma-rays was barely significantly different from that in 1956. The dose-rate outside the house in Belmont was also barely significantly higher than in 1956. The effect of the series of tests during 1957–58 and especially in October 1958, as well as the cessation of all tests since that time, is clearly demonstrated.

From spectrometric measurements we have made of the radioactivity in the air during the period, there can be little doubt that the increased counting rate was due principally to gamma-emitting fission products of relatively short half-lives, less than one year, namely zirconium-95 and its daughter niobium-95, together with ruthenium-103 and rhodium-106. The longer lived cæsium-137 would be present to a very much smaller extent due to the much lower fission yield. The variation of counting rate with time shown on the graph is in fact very closely in step with that shown by Peirson and Salmon[8] for the cumulative deposition of fission products at Milford Haven. The maximum increase in the local gamma-ray dose-rate, 25 m.rads/yr., which occurred during April 1959, is the same as that obtained by Spiers during May 1959 over a lawn in Leeds[7]. It is also very close to the value which may be calculated for Belmont, where the mean annual rainfall is about 25 in., on the observed relationship between rainfall and cumulative fallout[8].

Using both counters, the local gamma-ray background was measured indoors during April 1958 in one ground-floor laboratory at the Hospital and at several sites on the ground-floor of the house in Belmont. There was no significant increase above the values obtained in 1956 for the room in the Hospital and the average increase in the house amounted to about 4 m.rads/yr., which was about equal to the standard deviation of counting the difference. The maximum increase in the house was about 8 m.rads/yr., compared with about 10 m.rads/yr. out of doors at the same time. Large variations in the local gamma dose-rate indoors are of course expected due to the different shielding effects of walls and windows. For example, in the Hospital, where no increase in dose-rate was measured, the counter was protected from fission products on the ground outside by brick walls 20 in. thick. It is clear, however, that it might be unduly optimistic to assume a protection factor of 7 in all cases for the shielding effect of buildings, as was suggested in Appendix *M* to the Medical Research Council report[9]. It was unfortunately not convenient to make measurements indoors during April 1959, the peak period for the outdoor measurements, but the presence of fission products indoors at this time was clearly demonstrated by measurements of the gamma-ray spectrum from the refuse from a vacuum cleaner which was being used at the house in Belmont. By November 1959, the local gamma-ray dose-rate in the house was not significantly different from that measured in 1956, demonstrating that any fission products inside the building had decayed to a negligibly low level, in step with the conditions out of doors.

The significance of an increase in the local gamma-ray dose-rate outside of about 25 m.rads/yr. has been discussed very fully by Spiers[7]. It will be clear that the effective increase in man's radiation status is markedly dependent on the assumptions which are made with regard to the protection factor afforded by wash-off into drains and into the deeper layers of the soil, by the shielding effect of buildings and by the fraction of the day spent out of doors. The measurements reported here would indicate that the protection factors assumed in Appendix *M* to the Medical Research Council's report of 1956[9] with regard to the first two are possibly over-optimistic. There may also be large numbers of people for whom a period of 2½ hr. out of doors, the value used in the report, may also be optimistically low. In fact the measurements reported here are not inconsistent with the most pessimistic factors suggested by Spiers[7]; namely, that the dose-rate indoors due to fission products might be as much as 50 per cent of that outside, and that the dose-rate outside is roughly independent of the nature of the ground surface. If only 2½ hr. are spent outside each day, it would then follow that, by April 1959, the local gamma-ray dose-rate to which man was exposed, due to fission products in the environment, was about 14 m.rads/yr. greater than in 1956. Assuming that body tissues reduce the gonadal dose to two-thirds of this value[7], the genetically significant increase in the annual dose-rate would be about 9 m.rads. This is about 9 per cent of the total from the natural background radiation, which includes local gamma-radiation, cosmic radiation and radium and potassium-40 in the body[9]. If, therefore, testing recommenced and fallout continued at the same rate as 1957–58, the increase in man's gonadal dose from fission products on the ground might itself be greater than the total from all other man-made sources of radiation with the exception of that received from diagnostic X-rays[9]. It might be worth noting that plants and animals which are not protected by the shielding effect of buildings would receive additional gamma-ray doses about three times greater. They might also receive additional genetic doses from the beta-rays emitted by fission products, whereas the human gonads are protected from this source of radiation by the shielding effect of overlying tissues and clothing. The local gamma-ray background is, however, at the moment barely significantly higher than before large-scale nuclear testing began and, if there are no further tests, we might conclude that the increment of dose over the past three years is of small importance compared with, for example, the difference between the doses of natural background radiation experienced by persons in Leeds[1] and Belmont[8].

There will also be small additional doses to the whole body and the skeleton from internally deposited fission products, principally cæsium-137 and strontium-90 respectively. A report of our measurements of cæsium-137 in humans during 1958 and 1959 will be published shortly.

It is a great pleasure for me to record my appreciation of the work done by Miss S. Terry, who has been responsible for almost all the experimental work; amounting to about 1,000 separate measurements of the local gamma-ray background.

ANTIBODY PRODUCTION

By DR. STEPHEN V. BOYDEN*

Tuberculosis Immunization Research Centre, c/o Statens Seruminstitut, Copenhagen

THE mechanism of acquired immunity is as much a mystery to-day as it was sixty years ago. The facts which have come to light since then have provided little basis for choosing between the ever-increasing number of theories of antibody production. Even aspects of Ehrlich's side-chain theory[1,2], which was dropped almost completely for a time as a result of Landsteiner's work, are now being discussed seriously again, especially in view of some recent suggestions on the nature of immunological specificity[3,4].

The starting point for most speculation and experimental work on the mechanism of acquired immunity is, not surprisingly, the production of specific circulating antibodies in mammals. However, the failure of this approach to bring us much nearer to understanding the processes involved suggests that perhaps more consideration should be given to the possible origins of the phenomenon of antibody production in evolution. Some speculation from such a phylogenetic point of view has resulted in the suggestions which are discussed in this article. Although the hypothesis which is formulated does not seem to have been put forward in its entirety before, a large part of it is constructed of elements of the previous theories and ideas of others[1–9].

One of the most impressive features of the immune mechanism in vertebrates is its capacity to distinguish between constituents of the body and components of other organisms. Since the ability to discriminate between 'self' and 'not-self' is a necessary attribute of the phagocytic cells of the simplest multicellular animals, it is reasonable to suspect that this particular characteristic of immunity goes back very far in evolution—to periods long before the phenomenon of antibody production came into existence. In other words, the capacity for self-recognition is the most elemental of all the characteristics of the immune response, and it is therefore all the more remarkable that some of the important antibody theories scarcely consider this aspect of the problem, while in others the explanation for it represents the most far-fetched and the least satisfactory part of the whole argument.

---

* Present address: John Curtin School for Medical Research, Australian National University, Canberra.

It is becoming increasingly evident that the specific structure of molecules on cell surfaces in both unicellular and multicellular animals is an extremely important factor in connexion with the normal functioning and interaction of cells. Specific surface affinities or compatibilities are apparently responsible for a wide variety of cytological phenomena which involve adherence of one cell to another. For example, 'fertilizin', which coats the ova of various marine animals, has a specific affinity for the 'antifertilizin' on the surface of the sperm[10], and the re-aggregation of sponge cells which have been scattered mechanically is apparently due to the interaction of specific surface components[11]. It is also highly probable that surface 'antigens', characteristic for each type of cell, play a vital part in the organization of tissue in morphogenesis[12–14].

An interesting example of the importance of specific surface components in Protozoa, particularly in relation to feeding mechanisms, is provided by the case of *Entamoeba hartmonella* in which bacterial 'agglutinins' have been described[15]. If a suspension of this amoeba is mixed with certain flagellated bacteria, the latter can soon be seen 'clumped' on the surfaces of the Protozoa. Afterwards phagocytosis of the bacteria occurs. Apparently the fixation is due to the presence on the surface of the amoeba of molecules which have an affinity for components of the flagella of the bacteria.

It is not unlikely that in simple multicellular organisms in which phagocytes play such an essential part both in nutrition and in defence, similar surface factors may form the basis of the mechanism by which these cells recognize the foreign matter. We can envisage that the phagocytes are, like *Entamoeba hartmonella*, coated with molecules with structures complementary to bacterial components. However, for phagocytes to be effective in the defence of the animal against infection they must have an affinity for a much wider range of micro-organisms than does *Entamoeba hartmonella*. It is therefore necessary to assume the presence on their surfaces of a large number of different molecules of varying steric configurations.

Concerning the synthesis of these molecules, it is possible that the structural variation essential for the wide range of specificities might be achieved by the presence in the cells of a corresponding number of distinct ribonucleic acid templates. An alternative and somewhat more economical possibility is that only a single type of ribonucleic acid template is needed; but that the structure of the protein molecule is such that it is extremely versatile with respect to the number of possible shapes that it can take up as it folds after coming off the template (cf. ref. 6). The final specific affinity of each molecule would thus depend upon the shape taken up during this random folding process.

To account for the ability of the phagocytes to distinguish between 'self' and 'not-self', two possibilities can be considered. First, we can suppose that two types of cell are implicated in the process. One of these cells produces, and liberates into the body fluids, molecules possessing random affinities but all of which have also a second affinity for the surface of the phagocytes. Molecules in which the randomly determined specificity is complementary to self-components are soon 'neutralized' and removed from the body fluids. The others continue to circulate in the fluid until adsorbed by the phagocytes by virtue of their second and constant affinity for the phagocyte surface. Thus the phagocytes become coated with molecules complementary for many different 'determinant groups' other than those occurring on self-components. This idea of molecules with such 'double specificities' is not entirely fanciful, since it is known that sera of immunized mammals sometimes contain antibodies which have an affinity not only for the immunizing antigen but also for the host's own cells. Normal cells which have been treated with sera containing such antibodies are afterwards capable of specifically adsorbing the antigen[16–18].

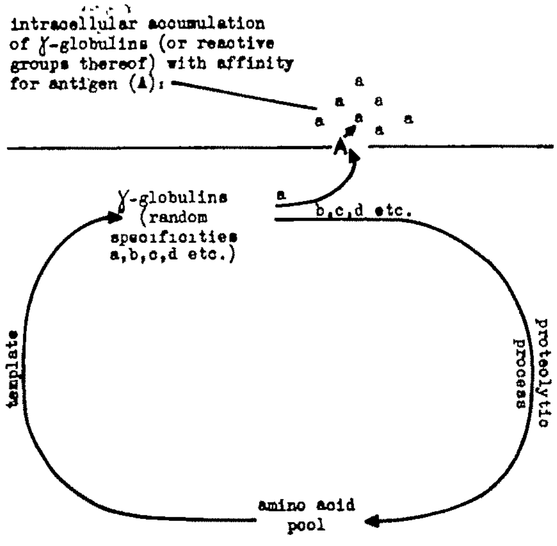
An alternative possibility would be that the phagocyte, like *Entamoeba hartmonella*, synthesizes its own 'receptor' molecules, but that the production of these ceases before the cell reaches maturity and before it is able to 'phagocytose'. Molecules with an affinity for 'self' would become 'neutralized' early on, so that by the time the phagocyte reaches maturity, only 'not-self' affinities would remain.

To account for so-called 'natural antibodies' in invertebrates we can postulate the production and release into the body fluids of molecules with random specificities but with no special affinity for phagocytes. Molecules with reactive groups for self-components are quickly absorbed out, thus never reaching harmful concentrations. Only molecules with 'not-self' affinities would tend to accumulate in the fluids.

It is suggested, then, that protein molecules of random affinities, especially coating phagocytes, play an essential part in the processes of feeding and microbial defence in the primitive Metazoa. We can now turn to discuss the specific immune response of higher animals, taking the view that its mechanisms are basically similar to, and in fact evolved from, those which are responsible for the ability of invertebrate phagocytic cells to recognize and respond to foreign matter.

The first step in antibody production must almost certainly consist of the uptake of the antigen by some kind of cell, and although absolutely nothing is known of how this comes about, it is not difficult to imagine that the specialized antibody-forming cells are coated, as was postulated for the phagocytes of invertebrates, with 'receptors' for a wide range of foreign molecules (antigens). We may suppose that these receptors are closely related to, if not identical with, γ-globulins. The actual shape and hence specific affinity of each receptor molecule might again be determined solely by the random folding process which follows its release from the ribonucleic acid template.

The usual inability of individuals to respond immunologically to their own proteins can be explained simply by assuming that the antibody-forming cells possess no receptors for self-components. The absence of 'self-receptors' on the cells can be accounted for, as in the case of the invertebrate phagocytes, by supposing either that the 'antigen receptors' are produced elsewhere and so 'neutralized' by the body's own components before they reach the antibody-forming cell, or that they are produced by the immature antibody-forming cell itself, and 'neutralized' before the maturation and development of the full potentialities of the cell. In either case the antibody-forming cells will possess no receptors capable of reacting with any proteins present in the circulation before the antibody-forming system itself



intracellular accumulation of γ-globulins (or reactive groups thereof) with affinity for antigen (A):

matures. This, of course, would be expected to apply also to foreign molecules if they happen to be present in the body before maturation of the immune mechanism (for example, at birth) and as long as they persist in high enough concentration to neutralize all the complementary receptors which are produced.

In connexion with the actual production of specific antibodies by the antibody-forming cell after it has adsorbed antigen, we make the following assumptions. In the first place, this specialized type of cell is capable of producing γ-globulin molecules of random specificities at an extremely high rate. Secondly, the cell is capable of breaking down these molecules at about the same rate as they are synthesized. In other words, there is a 'globulin cycle', consisting first of the synthesis from an amino-acid pool of γ-globulins of different specificities, and then of their catabolism by a proteolytic system to the constituent amino-acids.

It is assumed that the antigen, after combining with the 'antigen receptor', enters the cell and that the whole molecule (or determinant groups from it) becomes fixed to some cell component in such a way that it is protected from enzymatic breakdown, rather as has been postulated for the penicillin molecule in penicillinase adaptation in *B. cereus*[19]. The complex, consisting of antigen (or determinant group) and a cell component, is placed within the cell in close proximity to the site of the γ-globulin cycle of synthesis and breakdown. In this situation it interferes with the cycle by drawing aside any molecules which have an affinity for it, passing them on to a storage site elsewhere in the cell (Fig. 1). There is thus a competition between the proteolytic system and the antigen (or determinant group) for all molecules which tend to have an affinity for the antigen (or determinant group). Molecules with no affinity for the antigen will, of course, be broken down as previously.

Thus it is postulated that the presence in the cell of the antigen (or determinant group) is soon followed by the intracellular accumulation of γ-globulin molecules (or perhaps reactive pieces of γ-globulin molecules[20]) possessing an affinity for it. Once this accumulation has occurred, the cell itself must be regarded as 'modified'; perhaps some of the antibody molecules find their way to the cell surface, rendering the cell capable of taking up many more molecules of the same antigen. The consequent increase in uptake of antigen results in further accumulation of antibodies. The metabolic effects of these intracellular changes may be expected to stimulate cell division, so that, in the presence of antigen, 'modified' cells tend to multiply at a greater rate than 'normal' cells of the same series, resulting in the formation of clones of antibody-forming cells. Sooner or later most of the specific globulins, or antibodies, are released into the circulation.

It could be argued, on teleological grounds, that such a process would seem unlikely because it involves an enormous degree of wastage in the synthesis of γ-globulin. However, there are, of course, numerous examples in Nature of apparently wasteful phenomena. Moreover, in this instance there is no actual loss of building material, since the amino-acids are returned to the pool to be used again for further synthesis of γ-globulins, and the 'wastage' applies only to the energy used in the 'globulin cycle'. On the other hand, it is not essential to the main hypothesis to assume complete breakdown of the γ-globulin molecules. One could also suppose, for example, that only the last stage of the process, namely the folding, is reversible and that there exists a pool of γ-globulin molecules under conditions which allow a constant oscillation between the folded and the unfolded state, so that molecules with new affinities are continuously being formed. This possibility comes close to Pauling's theory[8], but differs from it in that it implies a selective rather than an instructive role of the antigen's determinant group.

Since this hypothesis does not require that the antigen modifies, either directly or indirectly, the structure of the γ-globulin molecules synthesized, it qualifies for inclusion in the category of 'elective', rather than 'instructive' antibody theories [21,22]. However, unlike the 'clonal selection theory'[21-25], which is also in the elective group, it does not assume any nuclear or somatic mutation. It does postulate a selection of certain cells, but it is a selection of cells which have become modified as a result of contact with antigen, and not, as in the clonal theory, a selection of genetic variants. (An essential difference between a mutant and the 'modified' cell is, of course, that the former would retain its capacity to be stimulated by antigen even if it continued to multiply for many generations in the absence of the antigen; the modified cell would not.) In this respect the possibilities discussed here are similar to the ideas put forward by Monod[9] and Pappenheimer *et al.*[26], who compare antibody formation with adaptive enzyme production in bacteria. They suggest that the antigen may be captured by a specific 'permease' on the cell surface, and that afterwards more of the same permease is produced so that the capacity of the cell for taking up the specific antigen is greatly increased. The increased uptake of the antigen results in further production of permease and of antibody, and also stimulates cell division.

According to the clonal selection theory, there exist in the mammalian body a vast number of different clones of antibody-forming cells, each producing its own special γ-globulin. When antigen enters the circulation it is thought to attach itself to the cells which have reactive sites corresponding to the determinant groups of the antigen, this resulting in a selective advantage for these particular cells. The consequent shift in cell population is reflected by an increase in the circulation of γ-globulins of the type produced by the selected cells. It is suggested that cell variants possessing reactive groups for self-components are eliminated either in the embryo[23] or before they reach maturity in the adult[21,22]. Since each cell is supposed to possess reactive sites for only one determinant group (or perhaps a few determinant groups), the elimination of all immature cells with self-reactive sites would mean the destruction of only a small proportion of the total number.

For several reasons the clonal selection theory, in contrast to the hypothesis put forward above, seems to imply that the mechanism by which the antibody-forming system recognizes foreign matter is in principle different from that by which the phagocytes of primitive Metazoa distinguish between 'self' and 'not-self' components. For one thing, the number of phagocytes in these minute animals is relatively very small, so that the chances for variation must be severely limited. Moreover, each phagocyte seems to have an affinity, not for just one determinant group, but for an almost infinite variety of foreign molecules. Considering the large number of reactive sites which this would entail per cell, the chances of a given immature variant arising devoid of reactive sites for self components would seem to be extremely small. It follows that elimination of all cells with self-affinities would mean destruction of the majority, rather than the minority, of the immature variants. In this instance it is surely easier to envisage elimination of the self-reactive groups themselves, rather than of the variants possessing such groups.

The hypothesis advanced here does not have any special advantage over most of the recent theories of antibody production ; like them, it is neither proved by, nor does it conflict with, the known facts. It is hoped, however, that it succeeds in emphasizing the need for more comparative studies, especially on very primitive metazoa. Metchnikoff wrote "... l'étude de ces animaux (inférieurs), que nous présentent des conditions bien plus simples et plus primitives que l'homme et les vertebrés, nous fournit pour ainsi dire la clef des phénomènes pathologiques compliqués"[27]. Although antibody production is not itself a pathological phenomenon, these words are nevertheless very much to the point ; in relation to the problem of specific acquired immunity they are as meaningful to-day as in 1892 when they were written.

VARIATION OF UPPER-ATMOSPHERE DENSITY WITH LATITUDE AND SEASON : FURTHER EVIDENCE FROM SATELLITE ORBITS

By D. G. KING-HELE and MRS. D. M. C. WALKER

Royal Aircraft Establishment, Farnborough, Hants

In a recent article in *Nature*[1], it was explained how the variations in air density at heights and latitudes near that of the perigee of an Earth satellite could be found from the rate of contraction of the orbit of the satellite. The method was applied to *Sputnik* 3 (1958δ2), and it was concluded that, for latitudes between 50° N. and 65° S., the air density at a height of 226 km. did not depart from its average value by a factor of more than 1·5 as a result of variations with latitude and season, and all other causes, such as solar disturbances[2-6] (which give rise to an oscillation with an amplitude of about ± 20 per cent) and a possible, much smaller, day-to-night effect. This conclusion conflicts with earlier direct measurements from rockets[7,8], which suggested a much wider variation with latitude and season, by a factor of 5 or even 10, at heights of 200–300 km. Since the subject remains rather controversial, it seems worth giving further results which have recently become available.

The latitude-range covered by *Sputnik* 3 (50° N.–65° S.) can be extended with the aid of *Discoverer* 6 (1959ζ), the orbit of which was inclined at 84° to the equator. *Discoverer* 6 was in orbit for two months, from August 19 to October 20, 1959, and during this time its perigee moved northward from a latitude of about 50° N. to 84° N., and then southward to about 50° S. The air density at the initial perigee height of 220 km., obtained by the method previously described[1], and expressed as a multiple σ of the average density, is plotted in Fig. 1. The points in Fig. 1 are at intervals of 6 days, during which time

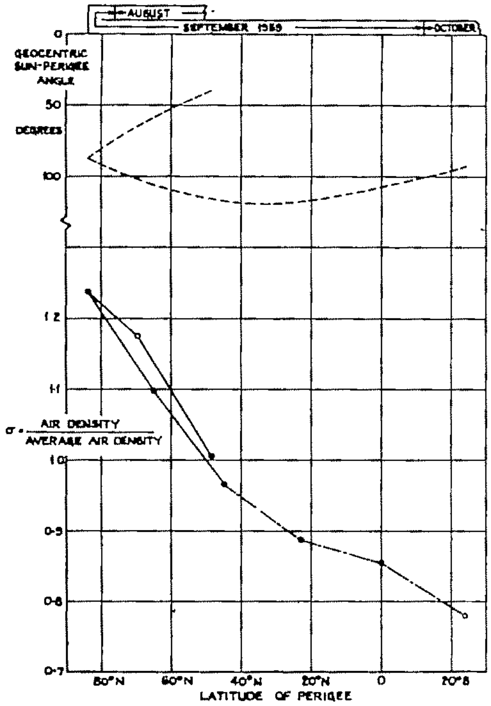

Fig. 1. Air density at a height of 220 km., deduced from the orbit of *Discoverer* 6: variation with latitude and time

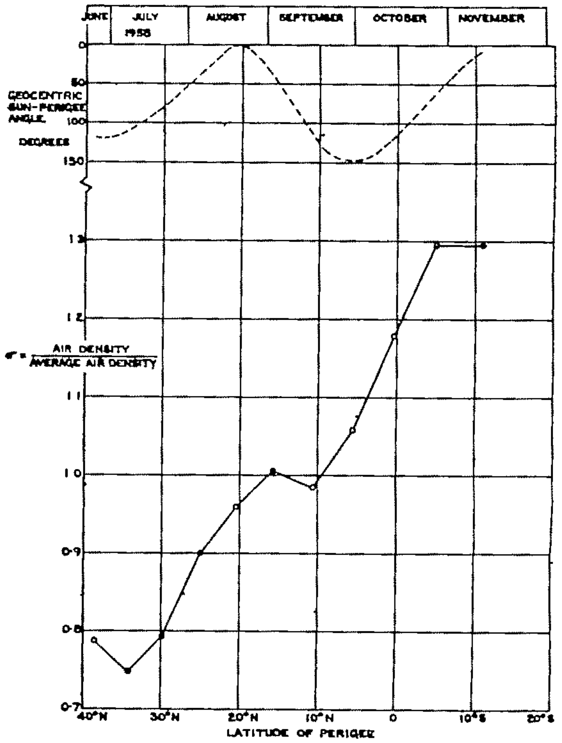

Fig. 2. Air density at a height of 220 km., deduced from the orbit of *Sputnik* 3 rocket: variation with latitude and time

the perigee latitude changes by about 20°. The main orbital data—the values of orbital period—were obtained partly from information issued by Project Space Track, Bedford, Mass., and partly from observations by the authors. Errors in the values plotted in Fig. 1 may arise from (1) errors in the orbital data, (2) errors in the assumed value for atmospheric scale height[1], and (3) changes in the mode of rotation of the satellite. The estimated standard deviation in Fig. 1 from these causes is a little more than 10 per cent.

Similar calculations have been made for the rocket of *Sputnik* 3 (1958δ_1), and the results are plotted in Fig. 2. This satellite[4] revealed strong and regular variations in air density, with amplitude about ±20 per cent and having maxima at intervals of about 28 days and minima at similar intervals. The points in Fig. 2 were calculated at intervals of 14 days, halfway between a maximum and a minimum, to smooth out these oscillations. The standard deviation in Fig. 2 is likely to be about 10 per cent, and again the relevant perigee height is 220 km.

The graphs in Figs. 1 and 2 represent, in effect, an average density over the range of latitudes near perigee where the air drag is important. For *Sputnik* 3 rocket the initial orbital eccentricity was near 0·1, and 80 per cent of the total drag effect occurred at latitudes within 15° of perigee. But *Discoverer* 6 had a lower initial eccentricity, 0·047, and the drag effect is therefore spread over a wider range of latitude, 80 per cent of it occurring at latitudes within 30 degrees of perigee. Towards the end of the life

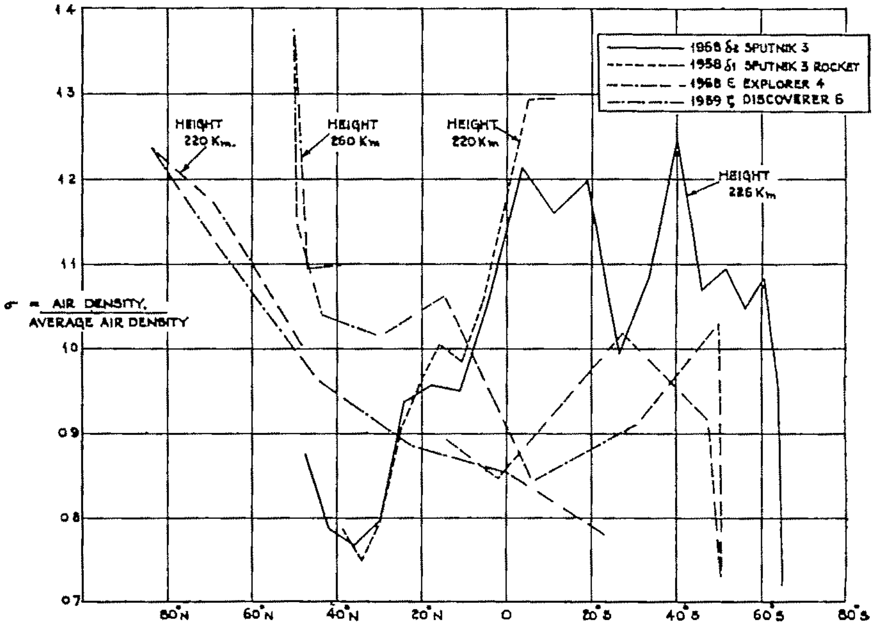

Fig. 3. Variation of air density with latitude at heights of 220–260 km, deduced from satellite orbits

of this satellite the spread in latitude is even greater, and the graph in Fig. 1 has been drawn as a broken line, since it does not represent realistically the detailed variation of density with latitude, though it does serve to indicate the average density in the equatorial region, for comparison with the density in north polar regions on the left of the graph.

Figs. 1 and 2 both confirm the earlier evidence that density does not depart from its average value, at heights near 220 km., by a factor of more than 1·5, and suggest that the variation due to latitude and season is probably a good deal smaller than this.

The angle *SCP* subtended at the centre of the Earth *C* by the sun *S* and perigee *P* of the satellite is also plotted in Figs. 1 and 2. If *SCP* exceeds 90°, the Earth below perigee is in darkness; if *SCP* exceeds about 108°, the perigee point itself is in darkness. The slight suggestion of a small variation in density between day and night indicated[1] by *Sputnik* 3 is given little support by Figs. 1 and 2. At heights around 220 km. it seems probable that day-to-night changes in density do not exceed ± 10 per cent.

The values of density at heights of about 220 km. given by *Sputnik* 3 (ref. 1), *Discoverer* 6 (Fig. 1) and *Sputnik* 3 rocket (Fig. 2) are plotted against latitude in Fig. 3, together with similar results for heights near 260 km. obtained from *Explorer* 4 (1958ε) by Schilling and Whitney[9] (though the method of presentation of these latter results has been altered, to fit in with the scheme of Fig. 3). The first point of interest in Fig. 3 is the close agreement between the results from *Sputnik* 3 and its rocket. This is to be expected because the perigees of the two satellites reached a given latitude at roughly the same dates and were therefore sampling the same regions of air. The small difference, averaging about 4 per cent, between the two sets of values suggests that the error inherent in the method of calculation is less than the 10 per cent mentioned earlier.

Apart from this close correspondence between the results from *Sputnik* 3 and its rocket, Fig. 3 is notable for an almost complete absence of significant structure: the only positive conclusion which might possibly be drawn is that density tends to be rather high north of lat. 50° N. and rather low south of lat. 60° S. On the whole, however, it appears more likely that the variations are unconnected with latitude. When the values of σ are plotted against the difference between perigee latitude and the declination of the Sun, to indicate possible seasonal effects, the resultant graph, which is not reproduced here, resembles Fig. 3 and again shows no sign of significant structure. The obvious conclusion is that the variations in density are controlled by time-dependent sources, for example, solar disturbances, rather than by latitude and season, which depend essentially on the position of the satellite relative to the centre of the Earth.

To sum up the results of this and previous work, it appears that solar disturbances are the main factor influencing the air density at heights of 200–300 km., giving rise to variations which have an amplitude of about ± 20 per cent and a periodicity of about 28 days. Day-to-night changes may also possibly have an effect, with the density not more than 10 per cent above average by day. Variations with latitude and season are small, and, when density is plotted against latitude or season, no consistent pattern emerges. At greater heights, 300–700 km., the variation from day to night is much more important[10,11] and has a greater amplitude than the 28-day variation due to solar disturbances.

THE APPROACHING DESCENT OF *SPUTNIK* 3 (1958δ2)

By B. R. MAY

Radio Research Station, Department of Scientific and Industrial Research, Slough, Bucks

SINCE *Sputnik* 3 (1958δ2) is nearing the end of its life-time, it may be of some interest to give a short account of its progress since the last review[1], and to discuss the likelihood of favourable observing periods from the British Isles, before its descent.

Throughout May, most of July, and August, the satellite was illuminated by the Sun on at least one transit each night, and on some nights as many as four consecutive transits were visible from the British Isles. This was due to the high declination of the Sun and the comparatively great heights (925 km., and above) at which the satellite traversed our latitudes. The fine weather enabled visual observers to obtain regular sightings, at stellar magnitudes ranging from + 3 to + 9. During June, however, the near transits occurred in the day-time, so that only radio observations were possible during that month. Since about the end of August the transits have been subject to varying eclipse conditions, and the number of visual observations made has generally decreased due to this, and to a greater extent, to the unfavourable weather conditions. Because of the rotation of the perigee of this orbit towards the northern hemisphere, the height of transit over our latitudes has been steadily decreasing since the end of June 1959, when apogee was at the maximum northern latitude. At the time of writing (February 15), the height of the satellite over our latitudes ranges from 220 to 470 km.

Since the perigee distance of this satellite is fairly small—about 6,560 km.—the magnitude of the atmospheric drag experienced by the satellite at its perigee will change appreciably as the perigee rotates over the oblate Earth. Thus, the estimation of the life-time of the satellite, which is based largely upon the drag, is subject to uncertainties even after the orbit is well known. In May 1959 a theoretical date of descent in early January 1960 was indicated—the present estimate places it in late March 1960.

For most of the few remaining weeks of the life of the satellite the near transits will take place in the day-time and, since the transmitters of the satellite are powered by solar cells only, good opportunities for radio tracking will be afforded. Transits for visual observations from the British Isles will occur from about March 16 onwards, in the mornings. Due to its low height, *Sputnik* 3 may well become a comparatively bright object, and it is hoped that this will increase the chances of valuable observations being made upon the last revolutions of this most interesting and successful satellite.

This communication is published by permission of the Director of Radio Research of the Department of Scientific and Industrial Research.

THE CANADIAN COMMITTEE ON OCEANOGRAPHY

THE Canadian Committee on Oceanography represents the re-organized Canadian Joint Committee on Oceanography which came into existence on April 1, 1946. It is comprised of representatives of the following Government agencies: Royal Canadian Navy, Fisheries Research Board, Department of Mines and Technical Surveys, Defence Research Board, National Research Council, Meteorological Branch of the Department of Transport, and Marine Services of the Department of Transport. In addition there are representatives of academic interests in oceanography nominated by the National Research Council.

The Committee is under the chairmanship of Dr. W. E. van Steenburgh, director general of Scientific Services, Department of Mines and Technical Surveys, Ottawa, Ontario. The secretary is Dr. H. B. Hachey, chief oceanographer, Fisheries Research Board of Canada, Ottawa, Ontario.

The functions of the Committee are to: (*a*) coordinate the oceanographic activities of all Canadian Government agencies; (*b*) act, as designated by the National Research Council, as the national committee for the Scientific Committee on Oceanographic Research; (*c*) act, as designated by the National Research Council, as the Section on Oceanography of the Council's Associate Committee on Geodesy and Geophysics.

Each of the co-operating organizations is either actively engaged in oceanographic investigations or contributes in ships, laboratory facilities, personnel or funds towards the Canadian programme, the total effort being co-ordinated through the Committee.

Activities coming under the Canadian Committee can be divided according to regions under investigation.

(*a*) *Atlantic coast.* This includes general surveys of the Gulf of St. Lawrence, the Scotian Shelf, the Bay of Fundy region, Newfoundland waters, and the Labrador and sub-Arctic seas; studies on slope waters and the mechanism of the Gulf Stream system, on the fundamentals of the Gaspe Current and Cabot Stream, on tides and currents, on cyclic variations in water temperatures, on problems of the varying influence of Atlantic and Arctic waters, on the formation and movements of ice, on biological, geological and geophysical problems, and special studies involving fisheries, naval and other national problems.

(*b*) *Pacific coast.* The work here covers general surveys of the waters of the eastern North Pacific, the Straits of Georgia and Juan de Fuca, Hecate Strait, and the fjord-like British Columbia inlets; studies on pollution in the sea as related to pulp-mill effluents and sewage; studies of current patterns and tides in Nature, and investigations of the fundamentals of flow by means of models; productivity studies, and variations in water characteristics as followed by observations at a network of coastal stations and from the Canadian Weathership; studies on biological, geological and geophysical problems and special studies involving fisheries, naval, and other national problems.

(*c*) *Arctic coast.* General surveys are being made of the waters of the Canadian Arctic, extending from the Bering Strait and Beaufort Sea to Baffin Bay and Davis Strait, with particular attention to the water characteristics in the various sub-areas and the volume and direction of flow through the various passages. An extensive survey is being undertaken of the Polar Continental Shelf, involving general oceanographic observations, tidal and current studies, geological, geophysical and biological investigations.

The work of the Committee is being carried out at a number of institutions. There is an Institute of Oceanography at the University of British Columbia, Vancouver, B.C., under the directorship of Dr. George Pickard, and an Institute of Oceanography at Dalhousie University, Halifax, N.S., has recently been set up under the directorship of Dr. F. R. Hayes.

The Pacific Naval Laboratory at Esquimalt, B.C., and the Naval Research Establishment at Dartmouth, N.S., operated by the Defence Research Board, conduct oceanographic research and surveys in support of military requirements.

Plans for the Bedford Institute of Oceanography, near Halifax, N.S., have been announced and the development is now under way. The Institute, which is to be completed in five years, will have a staff of 300 oceanographers, hydrographers, submarine geologists and other scientific personnel, plus supporting staff, and an operating fleet of ten oceanographic vessels. The Atlantic Oceanographic Group of the Fisheries Research Board will also be located in the Institute. This Institute will be under the Department of Mines and Technical Surveys. In support of its work, a substantial shipbuilding programme is planned. The first ship, the C.G.S. *Hudson*, which is expected to cost 7 million dollars, is to be commissioned in 1961. Dr. W. M. Cameron has recently been appointed to take charge of the development of the Bedford Institute. Widely known for his work in oceanographic research, Dr. Cameron has made special studies in the fields of biological and anti-submarine research. He is best known, however, for his Arctic studies and for his work in theoretical oceanography, particularly the theory of circulation in estuaries. His Arctic studies were mainly carried out as a member of the joint Canada–United States Beaufort Sea Expeditions, in which he was senior Canadian scientist. He was for a time professor of oceanography in the University of British Columbia, where he established an Institute of Oceanography. Since 1958 he has been director of plans of the Defence Research Board in Canada.

BIRDS AND FORESTS

THE Council of the British Trust for Ornithology has recently taken the initiative in promoting discussions with other bodies interested in economic aspects of ornithology. The second of its series of joint conferences was hold at Northerwood House, Lyndhurst, Hampshire, during October 30–November 1. The Forestry Commission was the Trust's partner in organizing the conference, and the subject was "Birds and Forests".

In opening the conference, Mr. E. M. Nicholson (Nature Conservancy) reviewed the relations between birds and forestry. He pointed out that remarkably little experimental work had so far been done in Britain to assess the part played by birds in the forest economy; the work of the Edward Grey Institute of Field Ornithology on tits and other birds in the Breckland and the Forest of Dean, and of H. N. Southern, of the Bureau of Animal Population, on the tawny owl in Wytham Wood, were examples of what could be done. He called for a new look at the problems of forest ornithology as a whole.

Mr. T. R. Peace (Forestry Commission) referred to the recent shift of emphasis from the idea of creating a strategic reserve of timber to that of economic forestry. This meant turning away from the natural forest towards a greater degree of deliberate tree farming. The Commission, as its creation of National Forest Parks has shown, was always prepared to pay attention to amenity; but economic considerations do not permit forests to be designed primarily for the encouragement of wild life. The Forestry Commission had not so far undertaken any research on problems of forest ornithology because it did not believe a case had yet been made out for birds being sufficiently beneficial to woodlands under British conditions to justify this.

In the subsequent discussion the point was brought out that the forester was faced with a choice between the small but continuing expense of providing and maintaining nest-boxes in order to increase the population of pest-predator birds and the much greater, but only very occasional, expense of attacking an infestation with sprays.

Mr. A. R. Mitchell (Forestry Commission) described the impact of forestry practice on bird life in woodlands. Wood-larks, for example, found forest nurseries a suitable habitat. On the other hand, the first thinning of a new plantation removed the forked and crooked trees in which birds liked to nest.

Dr. J. A. Gibb (Animal Ecology Section, Department of Scientific and Industrial Research, New Zealand; formerly of the Edward Grey Institute of Field Ornithology, Oxford) sent a paper describing the work of the Breckland Research Unit of the Edward Grey Institute with special reference to populations of insectivorous birds and their food supply in pine plantations. The Unit was able to demonstrate that the density of tits and goldcrests in the Breckland pine plantations (mainly 20–30 years old) in winter varied closely with their stock of food. In severe winters, the tits and goldcrests might be actually consuming 40 per cent of the total amount of insect food available for them, and very much larger proportions of the available supplies of their favourite foods. Though this did not by itself prove that the birds' numbers were being controlled in a density-dependent way by food shortage, it did prove the existence of the indispensable condition needed for this method of control to operate.

The result of the Breckland work was to suggest that the provision of nest-boxes, though increasing the local density of birds in the breeding season, could not enable a greater number of tits to survive the crucial winter season in any particular forest. It might indeed be more to the point to increase the stock of winter food available for the birds by planting suitable trees and shrubs on the forest margins to diversify the supply; for example, spruce and beech would provide autumn stocks of food for coal tits, which they could store for use in the winter (pines shed their seeds in spring).

As regards the impact of birds on insect populations, the Breckland researches showed that bird predation accounted for a substantial proportion of insect stocks, so that birds are a force to be reckoned with in forest economics.

Dr. Herbert Bruns (Staatliche Vogelschutzwarte, Hamburg) described various aspects of forest research on economic ornithology in Germany. Food studies showed that, on the whole, insect-eating birds fed chiefly on pest-insects, sometimes in large quantities. This did not, however, necessarily prove that they were important controls on these insects. However, there were several convincing examples in Germany where it could be proved that birds had actively controlled insect pests. In one pine forest in Baden it had been shown that insect infestation was much worse in nearly birdless monocultural plantations than in bird-rich woods nearby. When more nest-boxes were brought into the wood, the infestation was reduced.

Summing up, Dr. Bruns said that birds were not a panacea for all forest ills; but an important link in the natural chain of factors making for a healthy forest. Methods of sylviculture were most important, and it must be borne in mind that most German forests were much more mature than the average British forest. Much of the different British experience might be due to the immaturity of many British forests. The critical age for pest-devastation came at 60–70 years.

Mr. R. K. Murton (Ministry of Agriculture) discussed the control of wood-pigeons, which might be a serious forest pest, especially to the leading shoots of Sitka spruce and other species. In East Anglia at least the Forestry Commission could be absolved from generating a high population of wood-pigeons, for their plantations were too extensive. Dense nesting of wood-pigeons only occurs in a fringe about 100 yards deep around the edges of large blocks of woodland, since the birds are unwilling to nest very far from their feeding-grounds. Wood-pigeons therefore prefer to breed in hedgerows, shelter-belts and the small spinneys planted as shelter for game. The game preserver indeed was largely responsible for the existence of the plague of wood-pigeons in East Anglia, for in addition to providing their nesting places, he prevented any control measures until February, after the shooting season, when much damage had already been done to the crops of farmers and foresters. Moreover, it was the keeper who killed off the two principal predators of the wood-pigeon, the jay and the magpie, which are responsible for 80 per cent of the losses of wood-pigeons' eggs.

Dr. Bruce Campbell (British Trust for Ornithology) discussed population problems in a typical insect-eating forest bird, the pied flycatcher, illustrated by the ringing and nest-box experiments he was undertaking in the Forest of Dean.

Mr. W. A. Cadman (Forestry Commission) described the progression of wild life at various stages in the development of forests. He said that the pine marten had increased in some Welsh forests.

Mr. Nigel Gray (Imperial Chemical Industries Game Research Station) discussed the relations between game preservation and forestry. He said that good forestry made for good game habitat; but it was essential to have a reasonable mixture of tree species. If the Forestry Commission were to appoint game advisers, it would succeed in greatly boosting private forestry, by showing owners ho it could be combined with game preservation.

Dr. I. D. Pennie (British Trust for Ornitholog spoke about the capercaillie and its effects on woo lands. Foresters claimed that in autumn and wint the capercaillie ate almost exclusively the shoots an buds of conifers; but in fact it seemed much t prefer the shoots of transplanted trees in nurseri and plantations to those of naturally regeneratin trees. It was thus the shift in forestry practice, fro the natural woodland to the artificial plantation, tha had transformed this normal member of the woodlan avifauna of northern Europe into a forest pest i parts of Scotland.

There were two field excursions during the conference, one under Mr. B. Gale, with a forestry angl and one under Mr. Edwin Cohen, mainly for bird watchers.

R. S. R. FITTER

OBITUARIES

Mr. E. Price Evans

MR. EVAN PRICE EVANS died on April 27, 1959, at his home in Eastbourne, aged seventy-seven. He will be remembered for the part he played in introducing the teaching of plant ecology into schools; it is probably quite largely due to him that at least in some schools ecological teaching on scientific lines has taken the place of mere 'Nature study'.

Price Evans was a Welsh-speaking Welshman, born at Corris in Merioneth on January 19, 1882. Educated in his native village and at Towyn County School, he entered the University College of North Wales, Bangor, in 1900 and was trained to be a teacher. There he attended the botanical lectures of Prof. Reginald Phillips and Dr. (later Prof.) J. Lloyd Williams. His first appointment was at his own school at Towyn, under the headmastership of a notable chemist, Thomas Jones.

At Towyn he had already experimented with teaching field botany even to quite junior forms, and he later developed this teaching when holding a post at Ryhope, Co. Durham. In his youth, however, he was better known as a footballer than as a scientist and at one time played for Wales in the amateur internationals. From Ryhope he went to Warrington, where he became headmaster of the Grammar School.

At Ryhope from 1913 onwards he began teaching ecology and vegetation mapping to his classes, and his efforts in this direction led him to correspond with the late Sir Arthur Tansley, who was then at Cambridge. Tansley encouraged him to publish an account of his teaching methods in the *School Science Review*, and later they wrote in collaboration "Plant Ecology and the School" (1946).

Price Evans was a keen student of vegetation on his own account, especially that of his native mountains, which he knew very intimately. He contributed several papers to the *Journal of Ecology*, of which one dealing with Cader Idris is still the only published account of the vegetation of a geologically and botanically very interesting area and is often quoted. He was an accurate observer and kept notes methodically; his unpublished note-books are full of valuable observations on the plants and plant communities of North Wales. The University of Wale recognized his work by awarding him the honorar degree of M.Sc. in 1933.

During and after the Second World War, Price Evans was a keen supporter of Nature conservation and he was an active member of the Nature Conservancy's Committee for Wales from its inceptio until shortly before his death. He had a vigorou and friendly personality and will be much missed.

P. W. RICHARDS

Dr. Z. K. A. Moszynski

DR. Z. K. A. MOSZYNSKI, a principal scientifi officer of the British Coke Research Association died at his home in Chesterfield, Derbyshire, on February 13. Zbigniew Konrad Antoni Moszynsk was born at Lwow, Poland, on December 16, 1907 and studied in the Department of Chemical Engineering, University of Lwow (1927–34), where he took his diploma (Dipl. Ing.). During 1934–35 he worked in the Laboratory of Potassium Salts, University of Lwow. During 1935–39 he was deputy inspector for civil defence of industry, Polish Ministry of Defence in the County of Lwow.

In August 1939 he was mobilized and served in the Polish–German campaign, escaping to Hungary where he was interned. For five months he was assistant to the professor of agricultural chemistry University of Magyarovar, but in March 1940 he joined the Polish forces in France, being evacuated to England. On behalf of the Polish General Staff he carried out research work in the Mining Department University of Birmingham, between 1944 and 1945 on the use of carbonized peat/coal blends for mobile gas generators. During 1946–47 he continued and extended this work on the production of reactive carbonized fuels in the Fuel Department, University of Leeds, and obtained the degree of doctor of philosophy.

In September 1947 he was demobilized and in the same year became a British subject. He joined the staff of the British Coke Research Association, at the Midland Coke Research Station, where he was in charge of personnel and acted as secretary of a research group working on the analysis of coal and coke. His bomb combustion method for the determination of both sulphur and chlorine in coal is well known to fuel scientists, and is to become an international standard method. With the building of the new Coke Research Centre at Chesterfield in 1958 he transferred his home to Derbyshire and took up new work for the British Coke Research Association dealing with the problems of air and water pollution.

Physiology at Oxford :

Prof. E. G. T. Liddell, F.R.S.

The near prospect of Prof. E. G. T. Liddell's retirement from Oxford's Waynflete professorship of physiology has aroused a widespread interest among physiologists everywhere and, indeed, among all those who are concerned for the advancement by experimental research of knowledge in the medical range of the sciences. For there can be no doubt that the Waynflete chair, during the tenures of a succession of distinguished occupants, has achieved and maintained a reputation second to that of no other chair of physiology, anywhere in the world. Sir John Burdon-Sanderson and his pupil and successor, Prof. Francis Gotch, made contributions of fundamental importance to knowledge of the nature of nervous impulses, as excited and propagated in the continuity of nerve fibres. Under Sir Charles Sherrington the reputation of the Waynflete chair, and of the Oxford School of Physiology attached to it, attained additional eminence, through the discoveries which he and a series of distinguished associates made concerning the intricate phenomena of the central nervous system, involving the transmission of nervous excitations across systems of synaptic junctions of varying complexity; discoveries which have provided a large component of the foundation for modern neurological theory and practice. It is in this field of research, on the physiological processes of the brain and the spinal cord, that Prof. Liddell, as an intimate pupil of and collaborator with his great predecessor, has maintained that distinguished tradition.

Sir Lindor Brown, C.B.E., F.R.S.

Under Sir George Lindor Brown, Jodrell professor of physiology in University College, London, whose appointment to succeed Prof. Liddell in the Waynflete chair has recently been announced, it may be confidently expected that the tradition will be further maintained. After a distinguished student career in physiology at Manchester, Brown held a lectureship at Leeds, where the late B. A. McSwiney was then the professor. Work there, with McSwiney and others, gave early evidence of Brown's interest in the special physiology of the autonomic nervous system, and in the then recent evidence for a chemical mechanism of excitatory transmission at its ganglionic and peripheral junctions. With a grant from the Medical Research Council, he also worked for a period in Sherrington's Oxford department with J. C. Eccles. He then, in 1934, accepted an invitation to join Sir Henry Dale's team at the National Institute for Medical Research, and played a prominent part in extending the evidence for a cholinergic mechanism, to the transmission from motor nerve endings to the end-plates of voluntary muscle. Brown continued investigations in this general field with a series of distinguished colleagues and visiting experts after Sir Henry's retirement in 1942, having meanwhile become engaged in important war-time researches and responsibilities. In 1949 he became professor of physiology in University College, London, where another famous chair of physiology will be vacated by his removal to Oxford; and since 1955 he has been the biological secretary of the Royal Society. The chief focus of research-interest in the Oxford School of Physiology may, perhaps, move for a time from the central towards the peripheral nervous system; but there need be no fear of a lowering of its standard.

Astronomy at Oxford : Prof. H. H. Plaskett, F.R.S.

On September 30, Prof. H. H. Plaskett retires under the age limit, after twenty-eight years as Savilian professor of astronomy and director of the University Observatory at Oxford. His tenure of office has been notable for the building up of a school of solar physics, now well known for the thoroughness of its methods, the clarity of exposition in its lectures, and its avoidance of popular publicity. With only modest resources, two new solar telescopes and large spectrographs have been built and operated successfully. Prof. Plaskett's own work has been both observational and theoretical. He has studied models of the solar atmosphere, the formation of Fraunhofer lines, the structure of the solar granulation and problems of the chromosphere. Under his inspiration and guidance his colleagues and pupils have also made important contributions to solar physics. Among them they have discovered the strengthening of weak Fraunhofer lines from centre to limb, they have invented elegant interferometric methods for measurement of Fraunhofer and chromospheric lines, developed improvements in the mathematics of stellar atmosphere theory, and made long series of precision measurements to try to find whether the Einstein red-shift can be detected in the solar spectrum. Finding that the red-shift is obscured by spectrum line displacements arising from other causes, they have been led on one hand to study velocity fields in the solar photosphere, and on the other to make laboratory measurements of pressure shifts in atomic spectra of astronomical importance. Astronomy could well do with more of the devotion to careful measurement and the restraint on speculation which have characterized Oxford work under Prof. Plaskett.

Prof. D. E. Blackwell

Dr. D. E. Blackwell, who is to succeed Prof. Plaskett, has been assistant director of the Solar Physics Observatory, Cambridge, since 1948. He entered Sidney Sussex College in 1943 as a major scholar, from the Merchant Taylors' School, took first-class honours in both parts of the Natural Sciences Tripos, was an Isaac Newton Student in 1946 and Stokes Student at Pembroke College in 1947. His astronomical work has dealt chiefly with the solar corona and the zodiacal light. In a series of well-planned, adventurous and successful expeditions, in the Sudan for the 1952 eclipse, in an open aircraft at 30,000 ft. for the 1954 eclipse, over the Pacific in another aircraft in 1955, in the high Andes in 1958, he has extended optical measures until we now have reliable curves of brightness and polarization from the inner corona to the zodiacal light region 70° away. With M. F. Ingham he has photographed the zodiacal light spectrum with higher resolution than hitherto attained; their results have considerably altered our views on electron densities in interplanetary space and on the light scattered by interplanetary dust. They have also shown beyond doubt that the zodiacal light is sometimes variable. In 1956, and again in 1957, Blackwell and A. Dollfus made pioneer photographs of solar granulation from a balloon at 15,000–20,000 ft., using an 11-in. telescope, and demonstrated that most of the loss of telescope definition from bad day-time seeing can be avoided in this way. Dr. Blackwell is one who believes that observational astronomers must at all times seize upon any new techniques which promise significant advantage over older methods, and has acted on this belief with notable success.

Biology at Melbourne (Monash): Prof. A. J. Marshall

Dr. A. J. Marshall, reader in zoology and comparative anatomy in the University of London at St. Bartholomew's Hospital Medical College, where he is head of the Department, has been appointed to the chair of biology in the new Monash University in Melbourne, Australia. Dr. Marshall is an Australian by birth and upbringing; soon after entering the University of Sydney he joined the Oxford University Expedition to the New Hebrides, and then went to Oxford to help work out the results before returning to Sydney to finish his course and to graduate. During 1941–45 he was engaged in military service in northern Australia and New Guinea, and commanded the independent infantry "Jockforce" in the Wewak Campaign. In 1946 he returned to Oxford, where he obtained his D.Phil. and, later, D.Sc. degrees. In 1949 he resigned his Beit Memorial Research Fellowship to accept his appointment at St. Bartholomew's.

Dr. Marshall has always been a naturalist, and in his early years published a number of papers on natural history subjects in Australian journals. Under academic influence, and the guidance of Dr. John R. Baker and the late Dr. F. H. A. Marshall, his research interests concentrated on the physiology of reproduction in vertebrates, especially in its relation to behaviour, migration, and the ecology of breeding seasons. He has been strikingly successful in combining field and laboratory work by using the changing environment as a kind of natural laboratory. Key localities and situations, such as deserts, the arctic, early springs, and unusually severe winters, have been selected, and free-living birds, fishes, reptiles and mammals have been collected at periods, often in successive years, that were expected to yield the most valuable results upon subsequent histological investigation of their sexual cycles. He has always kept one foot in the field while the other was in the laboratory. One of his most important discoveries is the post-breeding metamorphosis of the seminiferous tubules in non-mammalian vertebrates into a mass of cholesterol-positive lipoid material which contains progesterone, and the somatic and psychological effects of the action of this hitherto undescribed endocrine gland. A very long series of papers by Marshall and his colleagues record these and cognate researches, crowned by his penetrating study of reproductive physiology and behaviour of the bower birds published by the Clarendon Press in 1954. Prof. Marshall will not only build up a first-rate teaching department at Monash, but will also undoubtedly establish a school of research in field-endocrinology, for which Australia offers unbounded opportunities, that will redound both to his own credit and that of his colleagues in the Old Country who first guided his steps towards this rewarding subject of research.

Cyto-Genetics at the Royal Botanic Gardens, Kew: Dr. Keith Jones

Dr. Keith Jones, a graduate of the University College of Wales, Aberystwyth, has been appointed a principal scientific officer at the Royal Botanic Gardens, Kew, to undertake research in cyto-genetics. Since 1948 he has been in charge of the Department of Cytology at the Welsh Plant Breeding Station, Plas Gogerddan, Aberystwyth, where his investigations have been connected mainly with European species of the Gramineae, in particular those of the genera *Agrostis*, *Anthoxanthum*, *Dactylis* and *Holcus*. He was awarded a doctorate by his University in 1957 for his thesis on "Species Differentiation in *Agrostis*", and recently spent a year studying at the Plant Research Institute, Ottawa, as a postgraduate fellow of the National Research Council of Canada.

Although Kew is internationally renowned for the beauty of its Gardens, it is primarily a research establishment concerned with the classification, determination and description of plants. For more than a hundred years its vast collections of herbarium specimens supplemented by living plants have been the subject of intensive morphological and anatomical studies. On the other hand, these unrivalled living collections, estimated to include some 45,000 species and varieties, have received comparatively little attention from the cyto-geneticists, and probably half of them have never been examined cytologically. Here, with such a wealth of desirable material, constantly being enriched by new discoveries, and representative of all groups of vascular plants and of very diverse phytogeographical regions, there is a unique opportunity for extensive cytological and genetical investigations. While the urgent need at present is for karyological studies, especially the determination of numbers and forms of chromosome sets, other lines of research, such as the genetical study of species and putative hybrids impossible of satisfactory classification by ordinary taxonomic methods, are also very necessary. It is hoped that this closer association of systematic botany, cytology and genetics at Kew will lead to the resolving of many difficult taxonomic problems and ultimately to a much improved and more natural system for the flowering plants.

Royal Society of Edinburgh: New Fellows

At a meeting of the Royal Society of Edinburgh, held on March 7, the following were elected Fellows of the Society: Dr. I. R. C. Batchelor, physician superintendent, Dundee Royal Mental Hospital, and head of the Department of Psychiatry, University of St. Andrews; Dr. D. Bijl, lecturer in natural philosophy, University of St. Andrews; Prof. T. L. Cottrell, Department of Chemistry, University of

Edinburgh; Prof. R. E. Coupland, Department of Anatomy, Queen's College, Dundee; J. A. Crichton, head of the Applied Nutrition Department, Rowett Research Institute, Bucksburn, Aberdeen; Prof. K. W. Donald, Department of Medicine, University of Edinburgh; Dr. W. J. Eggeling, conservation officer for Scotland, Nature Conservancy; Prof. R. B. Fisher, Department of Biochemistry, University of Edinburgh; R. S. Glover, officer-in-charge, Scottish Marine Biological Association's Oceanographic Laboratory, Edinburgh; W. Hutton, deputy-chairman of the South of Scotland Electricity Board; T. R. M. Lawrie, district geologist in charge of Highland work, H.M. Geological Survey, Edinburgh; R. D. Lord, senior lecturer in mathematics, Royal College of Science and Technology, Glasgow; Dr. J. A. Lovern, head of the Lipids and By-products Section, Torry Research Station, Aberdeen; Dr. D. M. C. MacEwan, lecturer in physics, Queen's College, Dundee; Prof. J. L. Malcolm, Department of Physiology, University of Aberdeen; Prof. J. A. Roper, Department of Genetics, University of Sheffield; Dr. F. A. Rushworth, lecturer in natural philosophy, University of St. Andrews; Dr. J. M. Shewan, head of the Bacteriology Section, Torry Research Station, Aberdeen; Prof. M. G. P. Stoker, Department of Virology, University of Glasgow; Prof. P. D. Sturkie, Department of Poultry Physiology, Rutgers University, New Brunswick (presently S.P.S.O., Agricultural Research Council Poultry Research Centre, Edinburgh); Prof. P. A. Sweet, Department of Astronomy, University of Glasgow; Prof. W. J. Tulloch, Department of Bacteriology, Queen's College, Dundee; Dr. G. B. Warburton, senior lecturer in charge of the Postgraduate School of Applied Dynamics, University of Edinburgh; Prof. P. E. Weatherley, Department of Botany, University of Aberdeen; Dr. R. Westwater, manager, Technical Service Department, Imperial Chemical Industries, Ltd. (Nobel Division).

Royal Geographical Society Awards

H.M. THE QUEEN has approved the award of the Royal medals of the Royal Geographical Society as follows: *Patron's Medal*, to Prof. Théodore Monod, director of the Institut français d'Afrique Noire, for geographical exploration and research in the Sahara; *Founder's Medal*, to Phillip G. Law, leader of the Australian National Antarctic Research Expeditions, for Antarctic exploration and research; *Victoria Medals*, to Dr. Armando Cortesão, for studies in the history of Portuguese cartography, and Prof. J. A. Steers, University of Cambridge, for research in coastal morphology; *Murchison Grant*, to Prof. J. Wreford Watson, University of Edinburgh, for contributions to the development of geographical studies in Canada; *Back Grant*, to A. T. Grove, University of Cambridge, for geomorphological studies in Northern Africa; *Cuthbert Peek Grant*, to G. F. Reid, directorate of Overseas Surveys, for contributions to Antarctic surveying; *Gill Memorial*, to Joyce M. Lambert, University of Southampton, for research in the origin of the Broads; and *Mrs. Patrick Ness Award*, to R. J. Adie, University of Birmingham, for contributions to Antarctic geology.

Institute of Metals Awards

THE Institute of Metals has made the following awards: *Institute of Metals (Platinum) Medal* for 1960, to Prof. Robert Franklin Mehl (head of the Department of Metallurgical Engineering, Carnegie Institute of Technology, Pittsburgh) in recognition of his outstanding contributions to the science of metals and to metallurgical education; *Rosenhain Medal* for 1960, to Prof. Norman James Petch (William Cochrane professor of metallurgy, King's College, Newcastle on Tyne) in recognition of his outstanding contributions in the field of physical metallurgy; *W. H. A. Robertson Medal and Premium*, for 1959, to Dr. Maurice Cook and Mr. E. Swainson (formerly chairman and assistant manager, Technical Department, respectively, Imperial Chemical Industries, Ltd., Metals Division, Witton, Birmingham) for a paper on "Arc Melting of Reactive and Refractory Metals", published in the *Journal of the Institute of Metals*, 87, 161 (1958–59).

Wolfson Research Professorship of the Royal Society

THE Council of the Royal Society has accepted with thanks the offer of the Isaac Wolfson Foundation to create a special fund of £200,000 for the endowment of a research professorship, to be known as the Wolfson Research Professorship of the Royal Society. The chair is to be held by a distinguished British scientist, who will devote the whole of his time to research in such fields as the President and Council of the Royal Society may from time to time think appropriate. The first holder, who has yet to be appointed, will work in the physical sciences or their borderlines with biology. The financial provision allows for adequate scientific and technical assistance for the Wolfson research professor.

Herald Reactor at Aldermaston

THE research reactor *Herald* of the United Kingdom Atomic Energy Authority started operation on March 7 at the Atomic Weapons Research Establishment, Aldermaston. It will be used for nuclear research work requiring intense neutron beams and for irradiation-damage studies on reactor materials. *Herald* is a light water-moderated and -cooled tank-type thermal reactor designed to operate continuously at 5 MW. The core of the reactor is in the form of thin plates of enriched uranium–aluminium alloy suitably spaced in water. A high flux density of thermal and fast neutrons of the order of 10^{14} neutrons per $cm.^2$ will be achieved. The reactor was built for the Atomic Energy Authority by the Associated Electrical Industries/John Thompson Nuclear Energy Co., Ltd., and is an adaptation of the *Merlin* reactor.

U.S. Council for the Advancement of Science Writing

A U.S. Council for the Advancement of Science Writing has been established. Its purpose is to stimulate an increase in the quantity and quality of science news that is carried in all media of mass communications—newspapers, television, radio, magazines and books for the general public. It plans to do this by fostering research and training in science journalism, and by sponsoring discussions and seminars on science writing throughout the United States. The aim is to heighten the public's understanding and appreciation of the scientific enterprise. The Council, a non-profit corporation registered in the State of New York, was set up through the efforts of the National Association of Science Writers. Among those elected to the Council at its first meeting in New York City were: *President*, Earl

Ubell, science editor, *New York Herald Tribune*, who also is vice-president of the National Association of Science Writers; *Vice-president*, W. Bradford Wiley, president of John Wiley and Sons; and *Secretary Treasurer*, Prof. Hillier Krieghbaum, Harvard University. Further information can be obtained from the Department of Journalism, New York University.

Scales of Temperature in the Meteorological Office

THE Director-General of the Meteorological Office has decided that from January 1, 1961, the celsius (centigrade) scale of temperature will be used for all work carried out within the Office. At present, the Fahrenheit scale is used for surface observations (air temperature, dewpoint, soil and Earth temperatures); the change to the celsius scale for aerological work having been made some time ago. The decision to employ only the celsius scale in professional work is in line with the recommendations of the World Meteorological Organization, and its adoption not only brings the Meteorological Office into line with all other European services but also will greatly facilitate the international exchange of meteorological information. The change will affect only the internal practice of the Meteorological Office, and at present there is no intention to remove the degree Fahrenheit from the published forecasts, or from replies to inquiries.

Sudan Natural History Museum, Khartoum

THE report for 1956–58 of the Natural History Museum, Khartoum, is the first to be published since the control of this institution was assumed by the University. Since its formation in the 1920's the Museum has had a chequered career, and it was only recently that it passed to the University of Khartoum. This association has enabled the Museum to draw freely on the specialized knowledge of the University staff and to develop according to a deliberate long-term policy. On the other hand, the Biological Department of the University benefits considerably by easier access to the technical skill and knowledge possessed by the staff of the Museum. It also enables the staff of the University to use freely the collections and records in the Museum for teaching and research. The constitution of the Board for the Natural History Museum still awaits the adoption of a statute by the University Council; but this formality has not prevented full co-operation for some time past.

Communicable Diseases in School

COMMUNICABLE diseases are one of the commonest causes of school absenteeism. A survey by the World Health Organization examines the statutory regulations in force in fifteen countries (Geneva. 3*s*. 6*d*.). The measures prescribed, of which the exclusion from school of sick children and of contacts is paramount, are compared with the recommendations found in medical literature. Health authorities tend at present to substitute surveillance for stringent measures. Surveillance presupposes well-organized school health services and the existence of bacteriological laboratories. The subject-matter of the study published in the report is arranged under the following headings: legislation, exclusion measures, obligations of parents, teaching staff and health services; measures relating to school staff; and closure of schools. An appendix contains an analysis in tabular form, by country and by disease, of the statutory measures taken in countries the legislation of which is covered by the study. It is surprising to find that there is virtually no uniformity whatever in the measures prescribed for dealing with the occurrence in schools of diseases the epidemiology, evolution and method of spread of which are well known.

Caroline Haslett Exhibition for a Woman Engineer

THE Caroline Haslett Memorial Trust announces that the first award to be made by the General Section of the Trust will be an exhibition to enable a woman engineer to visit the U.S.S.R. for the purpose of studying the training, employment and prospects of Soviet women engineers. Applications for the exhibition are invited from women engineers in the United Kingdom whose training and experience would fit them to make the proposed study. The visit will be a short one and will probably take place in the early autumn of this year. After her return to Great Britain the exhibitioner will be required to prepare a report for the Trust and to lecture on her findings. The Caroline Haslett Memorial Trust was established in 1958 to commemorate the work of the late Dame Caroline Haslett. Application forms, which should be returned before March 31, can be obtained from the Secretary, Caroline Haslett Memorial Trust, 25 Foubert's Place, London, W.1.

Horticultural Co-operative Marketing Societies

THE Minister of Agriculture, Fisheries and Food, the Rt. Hon. John Hare, is setting up a departmental Working Party "To consider and report on the methods and forms of association between horticultural co-operative marketing societies and their members, and whether these might be modified so as to give the societies more stability and continuity in their supplies of produce". Mr. J. B. Godber, joint parliamentary secretary to the Ministry, will be chairman of the Working Party, and it is expected to have its first meeting in mid-March. It will seek evidence from the agricultural co-operative associations and their constituent societies on the horticultural side, and from other persons with a direct knowledge of the subject.

University News: Bristol

THE following are announced: *Appointments*, to become lecturer in aeronautical engineering, Mr. J. W. Flower; to become senior lecturer in physics, Dr. W. M. Gibson. *Grants*, from the Department of Scientific and Industrial Research, £15,000 for an electron microscope, and £3,850 for an investigation in the Department of Physical and Inorganic Chemistry on the electronic spectra of ionized hydrocarbons; from the Royal Society, £2,291 to the Department of Physical and Inorganic Chemistry for the purchase of a high-temperature resistance vacuum furnace in connexion with investigations on the synthesis and chemical properties of carbides, silicides, borides and phosphides of metals. Biological material to the value of £2,800 has been received by the Department of Pharmacology from the Bingham Oceanographic Laboratories, Yale University.

Cambridge

THE Council of St. John's College, Cambridge, will make a Kenneth Craik Research Award for the assistance of persons engaged in postgraduate research, preferably in physiological psychology. The value of the Award will be £450 a year. Applications should be sent to the Master, St. John's College, Cambridge, to reach him not later than April 4.

London

MR. P. T. BAUER, Smuts reader in Commonwealth studies in the University of Cambridge, has been appointed to the University chair of economics (with special reference to under-developed countries and economic development) at the London School of Economics and Political Science. Mr. C. B. Winsten, lecturer in the Department of Mathematics at the Imperial College of Science and Technology, has been appointed to the University readership in statistics tenable at that College.

Dr. J. H. Green, senior lecturer in physiology in Middlesex Hospital Medical School, has been appointed to the University readership in physiology tenable at that School.

Nottingham

DR. R. W. HEPBURN, lecturer in moral philosophy in the University of Aberdeen, has been appointed to the chair of philosophy, in succession to Prof. W. J. H. Sprott, who has been appointed to a newly established chair of psychology in the University.

University College of North Staffordshire

THE following have been appointed to senior lectureships as from October 1: Dr. D. E. Davies (physics), Dr. J. P. de C. Day (philosophy), Dr. D. S. Lees (economics), Dr. R. McWeeny (theoretical chemistry), A. C. Montefiore (political and moral philosophy), and W. M. Williams (geography).

Sheffield

IT is announced that Dr. H. Ruben has been appointed as senior lecturer in charge of the Department of Statistics. The following lectureships are also announced: Dr. D. M. Burley (applied mathematics); Dr. Margaret M. Platts (medicine); H. A. Salmon (physiology)

Announcements

SIR ALEXANDER FLECK, recently chairman of Imperial Chemical Industries, Ltd., has been elected president of the Society of Chemical Industry for 1960/61 in succession to E. J. Solvay, and will be installed at the annual meeting of the Society at Bristol in July.

THE Philosophical Society of Washington has announced the election of the following officers for 1960: *President*, L. R. Maxwell; *Vice-presidents*, L. M. McKenzie and R. D. Myers; *Corresponding Secretary*, F. N. Frenkiel; *Recording Secretary*, M. M. Shapiro; and *Treasurer*, L. Slack. Further information concerning the society may be obtained from F. N. Frenkiel, Applied Mathematics Laboratory, David Taylor Model Basin, Washington, 7, D.C.

IN written answers to questions in the House of Commons about day-release students in technical education, the Secretary of State for Scotland, Mr. J. Mackay, on February 23 gave the number of boys and girls under eighteen released by their employers in Scotland for part-time education in the year ended July 31, 1958, as 17,934 out of 163,000 estimated employed at the end of May 1958. For England and Wales in 1957–58, Sir David Eccles on February 24 gave the figures 191,889 boys out of 578,000 and 50,636 girls out of 585,000.

IN a written reply to a question in the House of Commons on February 24 regarding the professional staff employed by the Atomic Energy Authority, the Minister of Education, Sir David Eccles, as representing the Minister for Science, said that of 4,223 qualified staff, 32 were biologists, 863 chemists, 2 geologists, 239 mathematicians, 990 physicists, 275 metallurgists, 113 chemical engineers, 184 civil and structural engineers, 505 electrical engineers, 1 mining engineer, 1,014 mechanical and other engineers, and 5 held the B.Sc.(Tech).

A SYMPOSIUM on the Formation and Breakdown of Hæmoglobin will be held by the Association of Clinical Biochemists in conjunction with the Biochemical Society on March 26, at the School of Chemistry, University of Leeds. Further information can be obtained from Dr. J. H. Wilkinson, Westminster Medical School, Horseferry Road, London, S.W.1.

THE Society of Instrument Technology is arranging a series of one-day conferences. The first is to be held at the Grand Hotel, Bristol, on March 22, and is entitled "The Value of Instruments and Automatic Control to the Smaller Firm". Further information can be obtained from Mr. A. E. Hiden, 13 Chestnut Road, Long Ashton, Bristol.

NORWOOD Technical College announces that a short course on an introduction to Micro- and Semi-microchemical Methods will commence on April 1. The course will consist of ten weekly lectures and appropriate practical work designed to survey the branches of chemistry in which micro techniques are applied. Further information can be obtained from the Secretary, Norwood Technical College, Knight's Hill, London, S.E.27.

A MEETING of the British Food Manufacturing Industries Research Association is to be held in Edinburgh at the McEwan Hall, University of Edinburgh, on March 30. The theme of the meeting will be Science and Food, and besides various speakers an exhibition tracing the history of the canning of foods will be organized. Further information can be obtained from J. B. Pollard, British Food Manufacturing Industries Research Association, Randalls Road, Leatherhead, Surrey.

UNDER the auspices of the Shell International Petroleum Co., an annual course for science teachers will be held at University College, London, during April 5–8. The opening talk will be given by Lord James of Rusholme, high master of Manchester Grammar School. Three exhibitions concerning oil and related subjects will also be mounted. Further information can be obtained from Mr. J. A. G. Croxson, Shell International Petroleum Co., 1 Kingsway, London, W.C.2.

A THIRD symposium on aspects of agricultural meteorology will be held at Aberystwyth, on March 16, when the subject will be "Upland Climate and Land Usage, with Special Reference to Highland Britain". Memoranda prepared in connexion with the two earlier symposia, on "The Growing Season" and "Shelter Problems", are being reprinted. Further information can be obtained from Mr. James A. Taylor, Department of Geography and Anthropology, University College, Aberystwyth.

PLANNING IN SCIENCE

IN recent years there has been a great deal of discussion in many countries on whether it is possible to plan science, the effect of such planning on science and whether planning does not of necessity threaten the freedom of scientific research or limit the initiative of scientists. These issues were discussed at an international symposium sponsored by the Czecho-Slovak Union of Scientific Workers and held in Prague's Hotel International during September 19–22. Some hundred scientists were present—forty from abroad, from Great Britain, the Soviet Union, France, Brazil, India, Japan, Greece, Poland, Bulgaria, the German Democratic Republic, Rumania, Holland, Denmark, Portugal and North Korea. An observer from Unesco was also present.

The first and fundamental question raised was whether science can, by its nature, be planned at all. The participants in the symposium, without exception, agreed that planning the main tendencies of scientific research and ensuring that they are in harmony with the needs of the country and the development of science is not only possible to-day but also imperative. Naturally, the conditions for the planning of science are very different in a socialist society from those in a capitalist society. However, as pointed out by I. Malek (Czechoslovakia): "Even though scientific development in the capitalist countries has taken its course to date without purposeful and uniform planning, the majority of scientists and public figures responsible for the development of science do not doubt the necessity of planning in some form". P. L. Kapitza (U.S.S.R.) attributed recent spectacular Soviet scientific successes to planning: "The socialist State has great advantages in so far as the planned organization of science is concerned; this is demonstrated by the fact that it was the U.S.S.R. which had the first satellite and also was the first to reach the Moon. We do not think that the quality of our scientists is better than that of scientists of other countries. We are all people and we all know the same, think the same, have the same brains in our heads and our heads are of the same dimensions. But we were able to mobilize the means and the scientists and concentrate them on an important task".

The symposium then went on to discuss whether the planning of science may not become a serious obstacle barring creative research activity. Many of those present admitted that misgivings along these lines could indeed be justified in some circumstances. Care must be taken in formulating the plan, never to forget the individuals who were to carry it out. As M. M. Shemyakin (U.S.S.R.) put it: "Every bit of planning, particularly co-ordination and organization of complex research, must bear in mind the individual creative ability of the worker. Pure administration would not be in place".

Dealing with the potentialities and limitations in the planning of science it was pointed out that in scientific planning the occurrence of unexpected factors, particularly the possibility of basic discoveries in the natural sciences, must be reckoned with. As J. D. Bernal (Great Britain) pointed out: "The difficulties are very largely unforeseeable at the start and it is necessary to change course, to make use of any accidental advantage that crops up, even to abandon the whole attempt and to begin in some other direction. Even then you may not succeed in what you originally aimed at, though maybe instead you will have picked up something unforeseen and even more interesting and useful".

The problem of who should plan and guide scientific research was the subject of lively discussion during which the specific nature of planning in science, requiring special procedure and the widest participation of scientific workers, was stressed. P. L. Kapitza directed attention to the new type of scientific director needed to carry through large scientific projects. Such a director, whose role is creative rather than administrative, may be a very great man even though he himself does not work creatively in science. Interesting light on how scientific administrators are chosen in the U.S.S.R. was given by M. M. Shemyakin: "All heads of laboratories and institutes, all heads of departments at universities are elected every five years by competition in secret voting of the scientific councils. These scientific councils are set up from leading scientists of the given institute and other institutes. The directors of the Academy institutes are also elected for a period of five years from among the most important scientists, also by secret ballot of academicians and corresponding members of the Academy of Sciences of the U.S.S.R. In this way a truly democratic system of directing science is achieved and pre-conditions for control are created".

A great deal of the time of the symposium was devoted to the discussion of the difficult problem of how the results of scientific research can be appraised. It was generally agreed that the appraisal must be done by scientists and certainly not based on financial criteria. But scientists themselves are by no means able always to judge correctly whether a given line of research is likely to lead ultimately to promising results. In the final analysis, J. D. Bernal pointed out, the results of scientific research must be tested in practice. But sometimes, owing to insufficient farsighted appraisal, promising lines of research never get the possibility of practical test. This leads to a great waste of opportunity and a time-lag in putting valuable ideas into practice.

Some of the most interesting contributions to the symposium described how planning operated in practice in a number of countries. In the socialist countries the tendency to proceed from short-term and detailed plans to long-term planning of the main trends and tasks was general. In the U.S.S.R., after a very broad discussion, thirty problems of the natural and social sciences were designated which were recognized as the most timely for the years 1959–65. The planning of science is especially thorough in Czechoslovakia, where a national plan of research including all branches of science and embracing basic and applied research right up to the production stage has been formulated by the Czechoslovak Academy of Sciences. This body is also responsible for securing the financial and material means necessary for carrying it out. Plans for scientific research in Poland, Bulgaria, the German Democratic Republic and North Korea were described.

The only paper describing the organization of science in a Western country was given by E. H. S. Burhop (Great Britain), who pointed out that although an aggregate plan of scientific research in any sense comparable with the plans of the socialist countries does not exist in Great Britain, nevertheless, laboratories working in related fields co-ordinate their work and in the field of basic research this method of free co-operation appears to work satisfactorily. Probably applied research could benefit from more co-ordinated planning, but this met with some difficulty in a social system based on competitive private enterprise.

It would have added to the interest of the discussion if accounts had been available of the organization of science in other Western countries. Nevertheless, the conference was of great value to participants in that it revealed both the similarities and the contrasts between the problems facing scientists in countries having different social systems.

RECENT GEOPHYSICAL WORK IN BRITAIN

At its meeting on January 27, the Geological Society of London held a symposium on "Geological Implications of Recent Geophysical Work in the British Isles", under the chairmanship of the president, Dr. C. J. Stubblefield. The afternoon session, devoted to the study of igneous rock masses, was opened by Dr. M. H. P. Bott, who outlined the results of recent work on the variation of gravity over granitic intrusions[1-3]. Particular attention was paid to the form of the gravity profiles over two bodies with contrasting features, the Hercynian Bodmin Moor granite and the Caledonian Criffell granodiorite. In the former case a negative anomaly of about 50 milligals could only be interpreted in terms of a large density contrast (thought to be about 0·16 gm./cm.^{3}) between granite and country rock. In contrast, a relatively small negative anomaly of some 20 milligals was recorded over the Criffell granodiorite; the gravity profile could not be straightforwardly interpreted in terms of a uniform density contrast and it was necessary to postulate a major gradational increase of density within the igneous mass towards its south-eastern margin. These conclusions, as well as the space forms deduced for the two intrusions, were not out of harmony with the results of earlier field and petrological studies. It was inferred that both intrusions extended to depths of the order of 11–12 km., more than one third of the normal crustal thickness in continental regions.

Sir Edward Bailey questioned the assumption that there was no significant increase in the density of granites with depth, and quoted examples such as the Ben Nevis complex where the reverse had proved to be the case. Dr. A. H. Cook thought that since it was impossible to estimate densities at depth with accuracy, there was no valid evidence for denying the possibility of granite masses extending down to the Mohorovičić discontinuity. Prof. T. Murphy commented on areas of positive anomaly which flanked the gravity lows over certain Irish granites and stressed the need to consider the regional picture as a whole.

Dr. Bott also discussed the relationship which often appears to exist between the mass deficiency over a granite, calculated from the gravity anomaly, and the excess mass of the topography. This comparison led him to the suggestion that the high topography frequently associated with outcropping granites may sometimes be isostatically compensated, but within the crust rather than at its base.

Dr. D. J. Blundell described some recent investigations carried out to examine the extent to which the magnetic properties of igneous rocks might be of use in geological interpretation. He instanced his own study of the Lundy dyke swarm[4], in the course of which he was able to show that the mean direction of magnetization of the intrusions agreed with that of Tertiary lava flows. Another example cited was the work of Dr. D. Armstrong on some minor intrusives of Ayrshire[5]. This showed that the kylites and crinanites formed two separate suites with distinct polarization directions, the former corresponding to the known Permian direction, the latter consistent with a Tertiary age.

Palæomagnetic work on the Newer Basic Intrusions of Aberdeenshire gave rise to some discussion. Dr. Blundell and Prof. H. H. Read[6] interpreted the results as indicating that the Huntley, Insch and Belhelvie gabbros had been intruded in approximately their present attitudes and had not suffered subsequent deformation, a conclusion carrying important structural and petrogenetic implications. Prof. F. H. Stewart and Prof. R. M. Shackleton found it difficult to accept the palæomagnetic evidence as conclusive, pointing out the need for more detailed study of the geology of the Insch mass and of the effect of such features as the ore mineralogy and the thermal history on the magnetic behaviour of the rocks.

Dr. D. W. Powell quoted difference in magnetic dip between two Scottish Lower Carboniferous basalt lava sequences, both of which contained reversals, indicating polar movement during the period. He commented also on the effect of compression on rock magnetization as shown by laboratory experiments.

Mr. S. H. U. Bowie described the results of an airborne radiometric survey of Devon and Cornwall carried out for the Atomic Energy Division of the Geological Survey[7]. This had disclosed a relatively even level of radioactivity over the different granite masses, though individual members such as the Castle an Dinas phase of the Land's End granite, as well as kaolinized areas in general, were markedly low in activity. Acid igneous rocks gave much higher values than basic varieties and there was a general tendency for radioactivity to rise in the late differentiates of granites. On Lundy Island, however, Dr. A. T. J. Dollar had found the earlier granite to be the most highly radioactive member of the complex.

The evening session dealt with the study of sedimentary basins and their sub-surface geology. The results of seismic work in the Carboniferous basin of the East Midlands and the Hampshire Mesozoic and Tertiary basin were outlined by Mr. R. G. W. Brunston and Mr. N. G. O'Halloran. With increasing knowledge of the general structural picture and the need for detailed exploration and study of individual structures in the course of the search for oil within these basins, gravity and seismic refraction surveys were now being superseded by seismic reflexion work. In the East Midlands many pre-Permian folds had been discovered by this method and afterwards confirmed by drilling. A smaller number of pre-Albian folds had been found in Hampshire and Dorset and the margins of the basin more accurately delimited.

Dr. W. Bullerwell described the results of aeromagnetic surveys over central, eastern and southern England carried out under contract for the Geological Survey. Regions of positive anomaly were located in the northern parts of Leicestershire and Northamptonshire, in the area surrounding The Wash, along a magnetic 'ridge' extending roughly from Reading to Birmingham and in the English Channel south-east and south-west of the Isle of Wight. Comparison of the magnetic map with the gravity map of the same area, based upon data provided by the Geological Survey, University of Cambridge and the British Petroleum Co., revealed many regions in which gravitational and magnetic anomalies showed clear positional relationships, either directly or inversely correlated as regards amplitude. The general picture of the sub-Mesozoic surface of central England was suggestive of a block pattern in which the trends of such familiar structural lines as the Lickey, Nuneaton and Charnwood 'axes' were discernible.

The combined gravity and magnetic data, supported by the evidence of deep boreholes, afforded a suggestion of a sub-Mesozoic surface of acid igneous material at relatively shallow depth between Market Harborough and Bedford; and of a north-westerly trending geosyncline filled with Lower Palæozoic sediments beneath southern East Anglia, an interpretation in harmony with views previously expressed by Sir Edward Bullard and others after seismic investigations in this area[8].

Recent research, outlined by Prof. W. B. R. King and Prof. W. F. Whittard, supplemented previous knowledge of the geological history of the English Channel and Western Approaches[9–11]. In the central and eastern Channel, seismic work had proved high-velocity rocks at much less depth than anticipated. It appeared that the Paris Plage Palæozoic ridge was of greater extent than formerly thought and must virtually have separated the Hampshire and Paris basins. Probably the Trias was absent over this ridge and the Jurassic succession much thinner than that in the Portsdown and Henfield borings to the north and the Pays de Bray to the south. In the Western Approaches, Prof. Whittard inferred a series of tongue-shaped outcrops ranging from Upper Cretaceous to late Tertiary, with the younger formations appearing progressively towards the south-west. On the continental slope indurated blocks of chalky material containing Recent, or at earliest Pleistocene, Foraminifera had been dredged from a depth of 500 fm.

Among other contributions dealing with marine geophysics was one from Dr. R. F. King describing seismic, gravity and magnetic surveys in the northern part of Cardigan Bay, supplementing previous work by Dr. D. W. Powell[12]. The density and seismic velocity of the upper layers suggested the presence of clays of late Mesozoic or Tertiary age. Mr. G. Armstrong described the use of the sub-bottom depth recorder (or 'sparker'), essentially a broad-band, high-powered, echo-sounder, using as a sound source either an electric spark or a small explosion. With this instrument the National Coal Board had obtained a reasonably comprehensive picture of the fault pattern, disposition of strata and distribution of igneous dykes off the coast of Northumberland and in the Firth of Forth. An oblique echo-sounder system which recorded reflexions from the sea-bed from a low-angle beam had been successfully applied for geological purposes in Weymouth Bay by Dr. D. J. Donovan and Mr. A. H. Stride.

A feature of the symposium was the variety of the techniques discussed and the complementary nature of the geological evidence obtained by different methods. It was noteworthy that many of these (aeromagnetic, aeroradiometric, 'sparker', 'oblique asdic') employed continuous recording along a chosen profile. Increasing use of such methods is an important trend in applied geophysics at the present time and their advantages both in speed of operation and for interpretation were pointed out towards the close of the evening by Dr. Bullerwell.

EVOLUTION OF ARBORVIRUS DISEASES

THE arborviruses (*ar*thropod-*bor*ne viruses) are those animal viruses which multiply in the tissues of the arthropod host and are transmitted in its saliva. The purposes of a symposium which had been arranged by the Royal Society of Tropical Medicine and Hygiene, and was held in London on January 21, were as follow: (1) to try to fit the arborviruses into current evolutionary theory; (2) to review current knowledge of arborviruses and suggest profitable lines of thought and investigation; (3) to interest workers in related disciplines, notably zoologists.

The first two papers dealt mainly with the origin and long-term evolution, the third mainly with evolution observable in our own time.

Prof. C. D. Darlington discussed the relationship between heredity and infection in plant, insect and animal viruses. Human viruses are particularly fruitful for study because while viruses are the most rapidly evolving of parasites, man is the most rapidly evolving, most varied and most widely distributed of higher organisms. Because viruses are wholly parasitic we have to consider the relations of harm or benefit between hosts and parasite. At the virus-level, the fundamental distinction in the basis of propagation is between the nucleic acids involved. In plants the two extreme forms of ribonucleic acid particle are the purely hereditary plasmagene of male fertility and the purely infectious particle of tobacco mosaic virus. Particles which are artificially transmissible by grafting, but not spread by natural infection, may be called proviruses, while viruses which apparently appear spontaneously or by chemical or physical treatment may be called new viruses. When vectors transplant viruses to new species the behaviour of the virus may change greatly, and when a vectored virus is artificially transmitted in series it may lose the capacity to infect the vector. A virus can become a harmless nucleoprotein (become latent) : or something hereditarily transmitted in the cytoplasm or generated by the cell in development may become infectious. Latent viruses which resemble the plasmagene in behaviour may arise from active viruses either in the capital host or the vector and may or may not be transmitted through the egg. Further evolution may lead to loss of infectiousness, as with Kappa in *Paramecium*, or the hereditary vector stage may be lost and only direct infections between capital hosts remain. Phages have evolved on a basis of alternating heredity and infection and it is possible that some viruses of higher organisms may also have done so. Heredity and infection seem, however, to be strict alternatives, for the viruses of higher organisms and hereditary particles are likely to persist only when they confer a benefit on the host. On the other hand, infectious particles owe their maintenance to the benefit they extract from the host, and harm to the host is relatively unimportant. The selection pressures are, therefore, opposed and when a hereditary particle becomes infectious they are switched.

Mr. P. F. Mattingly presented the view that the evolution of arborviruses has depended very largely on the ecology of their arthropod and vertebrate hosts. Despite their isolation in host tissues, each individual virus may be credited with an ecology of its own, just like other organisms. To appreciate this, secondary accretions such as adventitious transfer to man and occurrences in atypical hosts or vectors must be disregarded. When it was introduced into the New World, yellow fever rapidly found an ecological milieu very closely resembling that from which it had been liberated in Africa. The need seems to have been primarily for arboreal primate hosts. *Haemagogus* were available, in place of forest *Stegomyia*, and adaptation to these may have been relatively easy. Similarly the principal vectors of Wesselsbron virus in the low and high veldt (*Neomelaniconion* and *Ochlerotatus* respectively) are taxonomically distinct, but phenologically closely similar.

The present-day requirements for the establishment of a mosquito-borne virus appear to be the coexistence of warm-blooded vertebrates, angiospermous plants and blood-sucking mosquitoes. The two former are known to have evolved more or less together during the latter part of the Mesozoic and the viruses and their mosquito vectors probably evolved with them. The necessity of fitting into a complex ecological system may have slowed the rate of evolution compared with some other viruses. The fact that primate malaria can be transmitted only by anopheline mosquitoes while bird malaria is readily transmitted by culicines in the laboratory and, presumably, also in Nature, suggests that the anophelines originated as mammal feeders and the culicines, at least in part, as a bird-feeding group. The few known cases of virus transmission by anophelines, other than *Kerteszia*, appear to be adventitious or secondary. Basic maintenance cycles involve culicines only, except possibly in the subgenus *Kerteszia* which in some ways are more culicine than anopheline in their ecology. These facts suggest that the primitive mosquito-borne viruses were bird rather than mammal viruses. *Aëdes*-borne viruses are confined to the tropics. In the subtropics they are replaced by *Culex*-borne viruses and these in turn are replaced by tick-borne ones in the northern steppes. The explanation seems to be that *Aëdes* hibernate and æstivate in the egg, *Culex* as adults. In the relatively severe conditions prevailing in the subtropics hibernating adult mosquitoes appear to be necessary for the maintenance of virus. Farther north, only the resistant egg will serve for hibernation and *Aedes* become the dominant mosquitoes. But in the absence of transovarian transmission these are unsuited to the maintenance of virus, and mosquito-borne viruses are replaced by tick-borne ones. On the assumption that West Nile is the most primitive of the group *B* viruses, a picture can be drawn of invasion from subtropical swamp habitats to the northern steppes on one hand, and to a variety of tropical habitats on the other, with transfer to ticks and to *Aëdes* respectively. A simpler and more coherent picture would result from the assumption that the Russian spring–summer viruses were the most primitive, and the arguments previously adduced are worth reconsideration on this basis.

Dr. C. E. Gordon Smith concentrated mainly on the effects of intentional or unintentional human interference on the short-term evolution of arborviruses. About a third of the known arborviruses cause human disease ranging from severe encephalitis to mild fever—the remainder are still in search of a disease, but there are also many human febrile diseases which may be in search of a virus. Arborviruses are most numerous in the tropics and become progressively fewer as we go north or south to subtropics and temperate zones.

The viruses are usually maintained in their wild reservoirs without overt signs, and infections of man, and epidemics in man, spill over from these reservoirs under suitable conditions. Such infections are, however, without significance to the continued survival of the virus.

When a virus is in equilibrium with its hosts and environment (endemic or enzootic), the strain present is the one whose characteristics most perfectly fit the particular ecological complex. Under such conditions a virus mutant is very unlikely to be better adapted for survival than the parent form and is unlikely to succeed. Any change in the number or species of hosts or in the environment, however, provides conditions which may favour a new mutant, which may, by chance, be more or less virulent for man than the parent form. The sudden appearance of Kyasanur Forest disease in western India in 1955, and of a hæmorrhagic 'dengue' in the Philippines and Thailand in 1956, suggest that changes of these sorts must have occurred.

Among man's major activities the clearance of forest and introduction of new hosts to cleared areas are of outstanding importance. Unsuspected viruses may be liberated to establish themselves elsewhere. Russian spring–summer encephalitis became an important disease in Russia only when the taiga forests were cleared and settled.

Irrigation and subsequent agriculture in California brought changes in the flora and fauna which were responsible for epidemics of encephalitis, and increased agricultural activity in Tongaland appears to have led to greatly increased arborvirus activity there.

With the widespread use of insecticides, resistant arthropod strains emerge, and it is unlikely that they do not also differ from the parent form in other respects, such as vector efficiency for arborviruses. Arthropods do not appear to be adversely affected by arborvirus infection and it is not known whether their defence mechanisms interact with the viruses. In vertebrates the specific defence is antibody formation, but there are also the non-specific processes of inflammation and fever. Inflamed tissue is acid, thus a strain of virus with greater resistance to acid and which multiples better over 100° F. may prevail. In the arthropod, the length of the extrinsic incubation period is dependent upon temperature; thus, on the other hand, viruses which multiply better at, say, 70° F., might have an advantage.

A strain of virus capable of remaining latent in vertebrates for long periods might be maintained through periods when arthropods are not sufficiently numerous. Such latent infections with western equine virus have been demonstrated in birds and the stress of migration or ovulation might permit the virus to circulate when mosquito populations are becoming active in a temperate climate.

Opening the discussion, Dr. C. H. Andrewes suggested that there are two kinds of evolution to consider: the short-term with changes such as have been best seen in influenza, and the long-term, in which viruses as a whole may be very old and relatively stable. Viruses have a unique form of replication, which does not suggest that they are derived from host components. The ticks being probably more primitive than the mosquitoes might be more likely to have been the original hosts.

Several other speakers suggested pointers to the ticks as original hosts. Prof. D. S. Bertram pointed out that the one-layer covering of tick eggs may make them more susceptible to transovarial infection than mosquito eggs. Dr. M. G. R. Varma said that it appeared that while mosquito-borne viruses could multiply in ticks, tick viruses could not in mosquitoes. Dr. P. B. Stones suggested that if mosquitoes were the origin, then viruses ought to have been isolated from male mosquitoes: he reported an isolation of Semliki forest virus from a male *Eretmapodites* in Lagos.

Dr. J. S. Porterfield suggested that Semliki Forest virus may be the most primitive member of group *A* of arborviruses—a number of very closely related forms have now been isolated in Africa. He thought that Israel turkey virus may be a recent derivative of West Nile virus possibly resulting from man-made ecological changes.

On an analogy with transduction in bacteriophage, Dr. P. H. A. Sneath suggested that viruses are not true parasites, but may be partially derived from the reproductive mechanisms of their hosts.

C. E. GORDON SMITH

RED DEER AND VEGETATION IN NEW ZEALAND

AN expedition visited Lake Monk in the Cameron Mountains of Southern Fiordland, New Zealand, during March 26–April 5, 1957, to study the inter-relations of birds and mammals, particularly deer, with the vegetation (New Zealand Department of Scientific and Industrial Research, Bull. 135).

The vegetation was classed broadly into forest, scrubland, grassland and bogs. Mice and stoats are the only small animals in the area; the former are scarce and the latter are probably more widely distributed; from an examination of droppings they appear to be feeding mainly on birds. Red deer (*Cervus elaphus*) are thought to have reached the area about 1920, and to have built up a peak population between 1943 and 1950. They have since declined in numbers and are probably still declining. The population was composed of 50 stags to 35 fawns to 100 hinds, which are unusually low ratios; the deer were all in very poor condition.

The amount of grazing on the fern *Polysticum vestitum* was strongly correlated with the density of deer fæces, and could be used to provide an alternative index to deer abundance.

Counts of deer fæces showed that the animals in this area were spending more time in the forest than in the open grassland, although their preferred food at the time of year studied is grasses and forbs, but storms probably prevent the deer from spending as much time in the open as they would otherwise do. In the forest the beech seedlings are heavily grazed, but once established they continue to grow slowly. The saplings are hedged by deer; but the full amount of each year's growth is not removed and eventually a shoot grows above the browse-level There are sufficient pole-stage beech to replace the present generation of mature trees, and enough of the younger stage to ensure the continuance of the forest, although possibly with a lower density of trees.

The second-tier species in the forest, such as *Nothopanax colensoi*, *Griselinia littoralis*, and *Coprosma foetidissima*, have little resistance to browsing and the young stages of these species are only found in places inaccessible to deer. In the sub-alpine scrub there has been a widespread destruction of *Olearia colensoi*: grassland areas have been heavily used but show signs of recovery. On boggy areas the trampling of hooves has bared the ground around wallow holes.

The investigators concluded that red deer provide the dominant animal influence on the vegetation; but it is an influence superimposed on long-term trends due to climate and on short-term successional changes. The composition of the vegetation has been and is being altered by them in such a way that there is a marked increase in unpalatable plants, and a corresponding decrease in palatable plants. The resulting environment is relatively unfavourable to deer. In spite of these changes in the composition of the vegetation the forest, as a protective forest, is in no danger of being eliminated by deer; the total vegetative cover is not decreasing, and soil erosion in the area is negligible.

In the light of these findings an attempt is being made to define and clarify the wild-life problems arising from the use of this area as a national park.

THE LONG ASHTON RESEARCH STATION

THE volume of work reported in Long Ashton's annual report* is now so large that some selection is necessary to keep a review within manageable proportions.

Growth of apple fruits is dependent on the presence of seeds, but D. L. Abbott finds that this is so only during seven weeks after petal fall. C. Bould worked on the nutritional aspects of fruit production and found that yield and growth responses of Royal Sovereign strawberries in relation to nitrogen, phosphate and potash were those to be expected from leaf analyses of non-manured plants at the fruiting stage. This should provide a useful practical approach to the vital question of soil nutrient needs. Pollination is a necessary factor in fruit production, and it is surprising that relatively little is known about the distance over which a pollinator variety is effective. R. R. Williams found it to be about 90 ft. in one orchard, but only 50 ft. in another. A survey by A. I. Campbell and R. R. Williams of eighty orchards in Hereford and Somerset shows that difficulties encountered in headworking cider apple trees are in part due to apple virus diseases. It is sometimes necessary to clear old tree-stumps from land; E. W. Hobbis and J. S. Coles have investigated various possible rotting agents—aqua regia, caustic soda, bleaching powder, and a nitrogen–phosphate fertilizer. Only the last material showed any effect after four years. Workers in the pomology section also discuss the technique of measuring the assimilation of radioactive carbon by leaves, a survey and descriptions of perry pear varieties, and the forecasting of harvest date in blackcurrant varieties from their flowering dates.

A series of papers on spray application problems gives methods for the determination of spray residues —of gamma-BHC (J. A. Pickard), of microgram quantities of dieldrin (E. J. Skerrett and E. A. Baker), and of rotenone in *Lonchocarpus* (D. V. Richmond). A mercury content of 1 p.p.m. was found in coffee berries on trees which had received thirteen applications of mercury fungicide (J. A. Pickard and J. T. Martin). The plant cuticle is the immediate receptor for spray fluids, and J. T. Martin reviews current work on its nature and composition in several fruits and vegetable crops. Uptake of a fungicide (DMTD) by fungal spores (E. Somers), and the metabolism of certain aromatic compounds by fungi (D. Woodcock and R. J. W. Byrde) are also discussed. There has been quite a revolution in outlook on methods for spray application, and T. E. Cobbald briefly describes a prototype low-pressure twin-fluid atomizer. Fluorescent materials as tracers in spray liquids, and the vibrating jet method for the determination of dynamic surface tensions are two methods of assessing spray performance discussed in the report. Considerations of actual disease are mainly concerned with *Gloesporium* fruit rot, and entomology is represented by a paper on seasonal distribution of four species of leaf hoppers on apples. An interesting result of importance overseas is the finding of the fungus *Trachysphaera fructigena* on Jamaican bananas. The infection appears to have occurred in ripening rooms, from fruit from another source.

There are papers on cider and fruit juices and on domestic fruit preservation, as in previous years, and a list of 46 publications during 1958. It is announced in the introduction that the Agricultural Research Council's Unit of Plant Nutrition at Long Ashton was disbanded in September 1959. Members of its staff have, however, been absorbed into the work of the Station.

INFLUENCE OF NITROGEN-CONTAINING BASES ON THE RATE OF THE ELECTRODE PROCESSES AT THE DROPPING MERCURY ELECTRODE

By MRS. V. VOLKOVÁ

Polarographic Institute, Czechoslovak Academy of Sciences, Prague

A SPECIFIC effect of gelatin, amines, *p*-aminobenzoic acid esters of amino-alcohols and nitrogen-containing heterocyclic compounds such as various pyridine derivatives, alkaloids, etc., has been found[1,2] during the polarographic reduction of many organic compounds.

In respect of the polarographic waves, the effect on the reduction of substances capable of dissociation was of two kinds: on one hand, an influence on the height of the first wave, on the other hand, a considerable shift of the second wave to more positive potentials, often by several hundreds of millivolts.

The first case was observed chiefly with very weak acids, containing a heterocyclic nitrogen atom such as pyridine carboxylic acids, quinaldinic acid and oxyquinolines, and with corresponding aldoximes, further with α-Br-carboxylic acids, phthalic acid and benzaldehyde, the shift of the second wave being found with many reducible weak acids to such an extent that only a single wave was visible.

The effect on the first wave was originally explained by a reaction controlled by the recombination of the anion with the nitrogen-containing cation as proton-donor[1]. The recombination-rate constants thus obtained were of the order 10^{8}–10^{10} except with atropine and some other alkaloids, where considerably larger values were obtained which depended on the concentration of the nitrogen compound.

Since the above-mentioned catalysts are substances of strongly adsorptive character, attention has been directed to the study of the role that this property takes in the problem studied. The conception of the

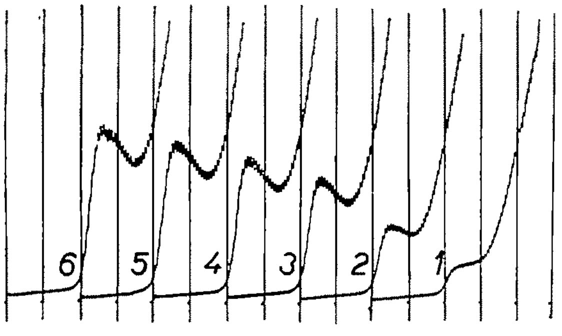

Fig. 1. Effect of amino-pyridines on the first wave of 10^{-4} *M* isonicotinic acid; borate buffer *p*H 10; concentration of 2-amino-pyridine: (1) 0, (2) 0·5 × 10^{-2} *M*, (3) 1·5 × 10^{-2} *M*, (4) 2 × 10^{-2} *M*, (5) 2·5 × 10^{-2} *M*, (6) 3 × 10^{-2} *M*; each curve starts at − 1·0 V. (vs. S.C.E., 0·2 V./absc.)

adsorption of the catalyst was supported in this case by the fact that the catalytic influence tended towards a limit with respect to the concentration of the catalyst. The influence of the adsorption of cations has been observed before in the polarographic reduction of inorganic anions; recently this case was thoroughly discussed by Frumkin[3]. Evidence for the adsorption occurring in our case as an accumulation of the catalyst at the electrode surface has been obtained from the study of *i–t* curves. When alkaloids, which have a large adsorption coefficient, were used as catalysts the effect of acceleration of the electrode process with time (a distinct inflexion on *i–t* curves) occurred at potentials where the mean current represented less than a quarter of the limiting current, but in the presence of pyridine derivatives and gelatin the *i–t* curves exhibited always the monotonous kinetic course.

The shape of *i–t* curves for different concentrations of the alkaloid (see Fig. 2 with phenylglyoxylic acid in the presence of atropine) corresponds to the concept of acceleration of the electrode process by the adsorption of a polarographically inactive substance with a large adsorption coefficient on the electrode surface. Because of the large adsorption coefficient, a certain period of time has to pass before the quantity of surface-active substance necessary for the saturation of the electrode surface is transferred to the electrode by diffusion.

Due to this increase of the surface concentration of the catalyst at the electrode the rate of the electrode process is also gradually increased until the limit concentration on the electrode is reached. The influence of the adsorption of an electrode-inactive substance with a large adsorption coefficient on the electrode processes of depolarizers has been theoretically solved by Weber, Koutecký and Koryta[4,5]. For the instantaneous current i at the beginning of the rising portion of the polarographic wave for periods of time smaller than ϑ (the time when the surface coverage has been attained) and for cases in which the rate constant at the occupied surface k_1 is distinctly larger than that at the free surface k_0 the following relation, $i \sim t^{7/6}$, holds evidently only in the case when the effective rate constant k_{ef} is a linear function of θ, the degree of the coverage of the electrode, and k_1 does not change with this degree of the coverage of the electrode. The relations between these quantities are as follows[6]:

$$\theta = \frac{\Gamma}{\Gamma_k} = \left(\frac{t}{\vartheta}\right)^{1/2}; \quad \vartheta = 1{\cdot}85 \times 10^{6} \times \Gamma_k^{2} \times c_A^{-2} D_A^{-1}$$

where Γ and Γ_k are the instantaneous and maximal concentrations of the catalyst adsorbed at the electrode surface, c_A the concentration of the surface-active catalyst in the solution, and D_A its diffusion coefficient.

The *i–t* curves at the beginning of the rising portion of the wave of the anion of phenylglyoxylic acid in the presence of alkaloids represent the most suitable example for the relations mentioned above. Although the exponent for $t < \vartheta$ was larger than 7/6 (up to 1·6) the dependence of ϑ on c_A^{-2} was found to be linear. Putting $D_A = 6{\cdot}4 \times 10^{-6}$ cm.²/sec. the area occupied by one molecule of atropine has been calculated as 93 Å.². The higher value of the exponent can be explained by the assumption that the adsorption is a kinetic process, or by the change of k_1 during the drop time with the change of θ or by supposing that for other reasons (the change in the value of the potential ψ_1) k_{ef} is not a linear function of θ. This will be the object of further investigations.

In the case of substances with a small adsorption coefficient the adsorption equilibrium is strongly shifted in favour of the non-absorbed form, so that Γ remains constant during the drop time and if the equilibrium is established very rapidly Γ can be expressed by any adsorption isotherm. Such a case can be solved for mean currents as in a normal slow electrode reaction[7]. If k_{ef} is a linear function of θ for suitably small concentrations for which θ is

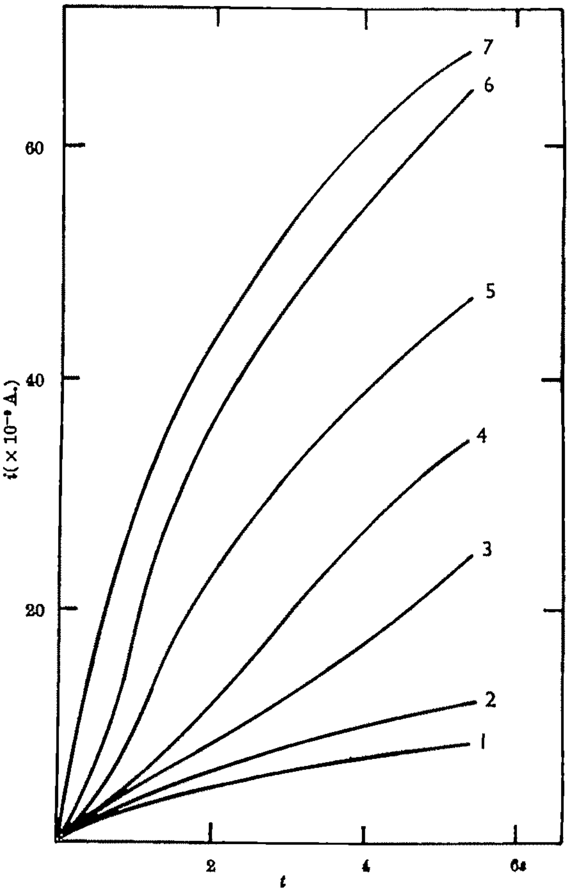

Fig. 2. Effect of alkaloids on *i–t* curves of 4 × 10^{-3} *M* phenylglyoxylic acid (as depolariser); borate buffer *p*H 8·6. *E* = − 1·04 V. (vs. S.C.E.); concentrations of atropine: (1) 0, (2) 0·4 × 10^{-6} *M*, (3) 3·3 × 10^{-6} *M*, (4) 5 × 10^{-6} *M*, (5) 8·3 × 10^{-6} *M*, (6) 13·3 × 10^{-6} *M*, (7) 23·3 × 10^{-6} *M*

also a linear function of the concentration of the catalyst in the solution and at a constant pH, then: $\frac{i}{i_d - i} \sim C_{\text{kat}}$. A good agreement of experiments with this relation has been found for some derivatives of pyridine.

A plausible explanation of the acceleration of the electrode process is as follows: since in all investigated cases the adsorption occurred at potentials at which the electrode has a negative charge, it can be assumed that the surface-active substances are adsorbed chiefly as cations. The circumstance that a very distinct acceleration of the electrode process occurs if anions are reduced or undissociated substances with the possibility of forming zwitterions such as *iso*nicotinic acid, hydroxyquinolines, pyridinealdoximes, etc., would support the assumption that a closer approach of the depolarizer to the electrode is made possible, perhaps because of a tendency to form an adduct. The distinct increase of the current of the second wave of phthalic acid which is ascribed to the reduction of the undissociated acid[8] could be explained by the assumption that the acid exists in the form with separated charges the electrode reaction of which is catalysed. The idea of thus influencing the reduction is supported also by the finding that in the reduction of a particle with a positive charge such as in the reduction of the cation of phthalic acid the presence of a surface-active substance as a cation causes a lowering of the current. There is no tendency towards the formation of an adduct in this case; on the contrary, the presence of the cation at the electrode surface causes a repulsion of the depolarizer with a positive charge and therefore a retardation of the electrode process must take place.

The details will be published elsewhere.

SOME SIMILARITIES AND DISSIMILARITIES IN THE STRUCTURE OF THE SKIN AMONG THE MEMBERS OF THE SUBORDERS ODONTOCETI AND MYSTACOCETI (CETACEA)

By DR. W. SOKOLOV

Department of Vertebrate Zoology, University of Moscow

THE members of two cetacean suborders, while possessing a number of similar features, show at the same time some essential differences. Obviously, the same relations must exist in the structure of their skin as well.

Up to now no attempts have been made to compare the structure of the skin in those suborders, although the cutaneous covering of some cetacean species has been studied by several investigators[1].

As material for the work reported here, samples of the skin from the following species of Cetacea were used: *Eubalaena glacialis* Bonaterre (obtained in 1955 by permission of the Minister of Fisheries *N*0113/2010, dated March 3, 1955), *Balaenoptera physalus* L., *B. borealis* Lesson, *B. acutorostrata* Lacépède, *Physeter catodon* L., *Berardius bairdii* Steineger, *Delphinus delphis* L., *Lagenorhinchus obliquidens* Gill and *Orcinus orca* L.

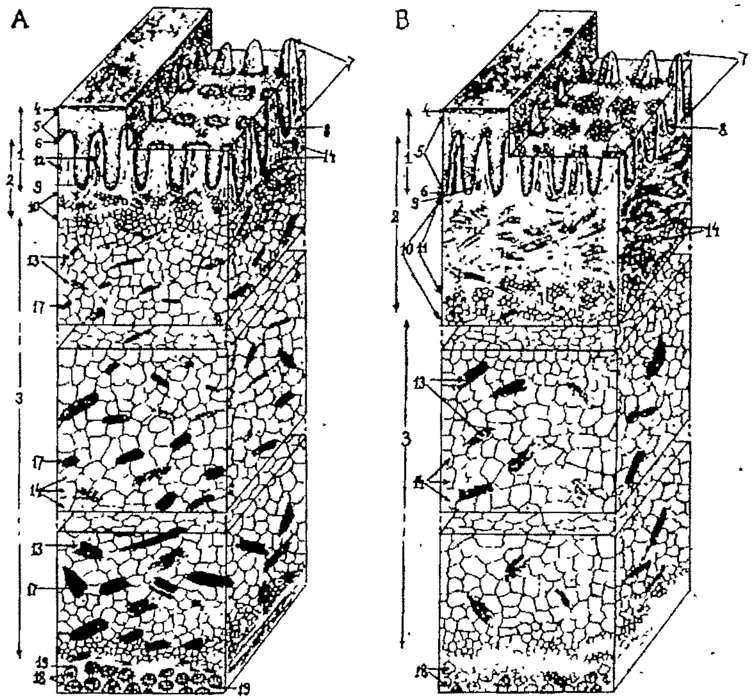
Most samples were collected during the expedition sent by the Institute of Oceanography of the Academy of Sciences of the U.S.S.R. (head of the expedition, S. Klumov).

Samples taken across the whole skin up to subcutaneous muscles were embedded in 'Celloidin'. Sections made by Christeller's method were stained with hæmotoxylin-eosin, after Van-Gieson and with resorcin-fuchsin.

Peculiarities of the cetacean skin common to all members of that order will be considered first. The cutaneous covering of Cetacea differs from that of other mammals by the absence of a continuous pelage and skin glands. Their skin consists of the following layers: the epidermis (Figs. *A*1, *B*1), the dermis (Figs. *A*2, *B*2) and the subcutaneous fat tissue (Figs. *A*3, *B*3). The limit between two latter layers is slightly marked. The epidermis, though reaching considerable thickness, consists of only three layers: the outer one, called conditionally the corneous layer (cornification does not take place in it and its cells retain nuclei) (Figs *A*4, *B*4); the underlying stratum spinosum or prickle cell layer (Figs. *A*5, *B*5); and the deepest basal layer (Figs. *A*6, *B*6). On the inner surface of the epidermis numerous alveoli are distributed, in which dermal papillæ rise vertically upwards (Figs. *A*7, *B*7). The epidermis may be pigmented, the pigment in the form of finest granules being disposed in the epidermal cells and localized above the cell nucleus. At the limit between the epidermis and dermis melanophores sometimes occur.

The dermis of Cetacea consists of dermal papillæ (Figs. *A*7, *B*7) and of a sub-papillary layer (Figs. *A*10, *B*10) in which a non-adipose layer (Fig. *B*11) adjoining the epidermis may occasionally be seen. The dermal papillæ are formed of thin bundles of collagenic fibres rising vertically upwards along the long axis of the papilla, and of a few elastic fibres running in the same direction. Small blood vessels rise to the top of the papilla (Fig. *A*12). No fat cells are present in the dermal papillæ. In the sub-papillary layer of the dermis bundles of collagenic fibres (Figs. *A*13, *B*13) are situated at various angles to the surface of the skin, forming a more or less dense network. Elastic fibres may be numerous. The thickness of the latter as well as that of the bundles of collagenic fibres is considerably greater than in papillæ. Fat cells (Figs. *A*14, *B*14) are disposed either immediately at the epidermis itself or at some distance from it, in which case a non-adipose layer (Fig. *B*11) with a very compact network of bundles of collagenic fibres will be formed. The dermis passes gradually into a subcutaneous fat tissue (Figs. *A*3, *B*3) in which collagenic fibre bundles (Fig. *A*13, *B*13) are disposed far from each other, the whole space between them being filled up with enormous accumulations of fat cells (Figs. *A*14, *B*14). With their removal from the epidermis the bundles of collagenic fibres become thicker and the fat cells grow larger, decreasing only in size near subcutaneous muscles. Elastic fibres and large blood vessels are but few in the subcutaneous tissue. A vast number of capillaries pass between the fat cells.

In describing differences of the skin in two suborders of the order Cetacea, two families, Balænopteridæ and Balænidæ, among Mystacoceti, have to be considered separately because the skin of the latter combines characters of both the Odontocete and Balænopteridæ. The skin of ***Eschrichtius gibbosus***, family Eschrichtiidæ, has not been studied.



A scheme of the skin structure in Mystacoceti (*A*) and Odontoceti (*B*)
1, Epidermis; 2, dermis; 3, subcutaneous fat tissue. Epidermal layers: 4, corneous; 5, stratum spinosum or prickle cell layer; 6, basal; 7, dermal papillæ; 8, longitudinal septa of epidermal alveoli; 9, transversal septa of epidermal alveoli; 10, subpapillary dermal layer; 11, non-adipose part of subpapillary dermal layer; 12, blood vessels in dermal papillæ; 13, bundles of collagenic fibres; 14, fat cells; 15, epidermal projections extending into the tissue of dermal papillæ; 16, oval form of the diameter of epidermal alveoli; 17, bundles of elastic fibres; 18, bundles of striated muscle fibres in subcutaneous muscles; 19, elastic fibres surrounding bundles of striated muscle fibres in subcutaneous muscles

On a tangential section of epidermis the epidermal alveoli of Balænopteridæ and of the surface-swimming Odontoceti have the form of an oval (Fig. *A*16), the long axis of which is directed along the animal's body. In deep-diving Odontoceti (*P. catodon* and *B. bairdii*) and in *E. glacialis* the form of the alveolus diameter is rounded almost over all their height (Fig. *B*). Epidermal septa delimiting the alveoli on a tangential section on their long sides (in parallel with the long side of alveolar oval) and which are called longitudinal septa, in Mystacoceti (Fig. *A*8) penetrate deeper into the subpapillary layer of the dermis than transversal septa (Fig. *A*9). But in most Odontoceti their height is nearly equal (Figs. *B*8, *B*9). In the epidermis of Odontoceti projections from epidermal septa (Fig. *B*15) grow into the tissue of dermal papillæ (Fig. *B*7). In *D. delphis* and *L. obliquidens* projections are absent, but there exist separate projecting epidermal cells. In Balænopteridæ the epidermal septa have no projections except small ones found in *B. acutorostrata*. In *E. glacialis* projections reach a considerable size. The functional significance of those projections consists in increasing the strength of cohesion between epidermis and dermis and in enlarging the area of the producing surface of epidermis, namely, of its basal layer.

In more cold-loving Balænopteridæ the subpapillary layer of dermis is nearly absent, being replaced by a subcutaneous fat tissue (Fig. *A*3). Fat cells are located immediately under the epidermis, creating thereby a reliable thermoisolation. In most Odontoceti the subpapillary layer of dermis is well marked (Fig. *B*10), a non-adipose layer being usually present therein (Fig. *B*11). A more active mode of life in predatory whales seems to make necessary the presence of a skin layer exposed to a considerable mechanical loading, when pursuing the prey. *D. delphis* and *L. obliquidens*, due to their comparatively small body-size, require a better thermo-isolation than large whales. Therefore, their subcutaneous fat tissue is relatively more developed than in other Odontoceti. *E. glacialis* has a well-developed subpapillary dermal layer with a non-adipose part in it.

The correlation between the dermis and the subcutaneous fat tissue must change according to the seasons of the year, and it is quite possible that in the dermis of all Odontoceti large accumulations of fat cells are formed in winter. We had no samples of the skin from whales obtained late in autumn or in winter, so our description refers to the summer period only.

Characteristic feeding habits of Balænopteridæ are connected with a considerable mobility of their skin, particularly on the ventral side of the body. Owing to this characteristic the net of elastic fibres is strongly developed in their skin. Besides, there are numerous specific bundles of elastic fibres (Fig. *A*17) scattered in the subcutaneous fat tissue. Moreover, in their subcutaneous muscles bundles of striated muscle fibres (Fig. *A*18) are surrounded by numerous elastic fibres (Fig. *A*19) running along them. In Odontoceti the net of elastic fibres in the skin is much less developed, bundles of the same fibres are absent in their subcutaneous fat tissue and there are no elastic fibres in subcutaneous muscles (Fig. *B*18). Active *D. delphis* and *L. obliquidens* possess dense nets of elastic fibres, and at the limit with their subcutaneous muscles plexuses of elastic fibres or even small bundles are to be found. In *E. glacialis* there is an ordinary net of elastic fibres, bundles of the latter being few in the subcutaneous fat tissue.

In subcutaneous muscles of the above-named whale elastic fibres are rare.

In Mystacoceti the skin of the snout has separate profusely innervated sensory hairs. In most Odontoceti there are no hairs in the post-embryonic period, but they are present in embryos. *Monodon* and *Delphinapterus* have no hairs at all even in the embryonic condition.

Besides all the characters indicated above the skin of Balænopteridæ is distinguished by the presence of longitudinal folds on the greater part of the body's ventral side, with the thickest epidermis, its corneous layer, the subpapillary dermal layer and the highest dermal papillæ at the tops of the folds. A gradual decrease in the size of those elements occurs towards the bottom of furrows between the folds.

AN ANTIBODY INHIBITOR

By Dr. JACK G. MAKARI

Director of Research, Muhlenberg Hospital, Plainfield, New Jersey

IN our outlook on immunology in relation to disease we have specifically concentrated on antigens and antibodies, and we have attempted to explain all humoral host responses in these terms. Clearly there are areas which are not explained by this limited concept. What happens to the host before an antibody is produced ? Does the body lack an early mechanism to tie up an invader before the antibody is formed ? What does the body do in order to rehabilitate its reactive globulins or to stop the production of antibodies when the antigenic stimulus disappears ? Furthermore, we have mounting evidence to show that auto-antibodies directed against the host's own constituents are being formed in even so-called normal humans. How is this auto-antibody handled ? How is it tied up so that it cannot reach its target ? Furthermore, how do we explain psychosomatic influences, hormonal factors, and the impact of stress on the organism in terms of immunology ?

All these factors require that we expand our concept of host defences to include a triad of antigen, antibody, and inhibitor as follows :

$$\begin{tikzcd}
\text{Antigen} \arrow[rr, shift left] \arrow[dr, Rightarrow] & & \text{Antibody} \arrow[ll, shift left] \\
& \text{Inhibitor} \arrow[ur, Rightarrow] &
\end{tikzcd}$$

I have for many years been interested in this mechanism. I have described an inhibitor earlier[1], studied some of its behaviour *in vitro* as demonstrated by its capacity to inhibit flocculation of normal globulins in the presence of cephalin cholesterol emulsion, and investigated its behaviour by means of serial cephalin flocculation curves[2].

Previously I found that immunization resulted in an increase in this inhibiting factor prior to and independent of the specific antibody response. Drugs (such as antimalarials), alcohol, emotional excitement, stress and even physiological mechanisms, such as food and physical exercise[3], all influenced this response. Furthermore, in the study of host-parasite interaction, as occurs in malarial infection, it was apparent that this inhibitor was a resistance factor of vital significance to the host[2].

In this present study evidence is presented to show the dual function of this inhibitor. For this same inhibitor, which can inhibit the flocculation of globulins in the presence of cephalin–cholesterol–ether emulsions, is, in fact, an antibody inhibitor, capable of preventing the fixation of antibodies to uterine segments in the Schultz–Dale test.

In the preliminary experiment shown in Table 1, the source of antibodies for this *in vitro* fixation to uterine segments was the serum from patient *P.*, a case of active melanoma tumour with metastasis, and from patient *B.*, a case of leukoplakia without any evidence of tumour. The two uterine horns (obtainable from a healthy, unsensitized guinea pig) were then removed. Each of these horns was then cut in half into two segments. The resulting four segments were then ready for coating. Two of these uterine horns were immersed in 0·5 ml. of serum diluted with 0·5 ml. of Tyrode solution ; the other two segments were immersed in 0·5 ml. of serum diluted with 0·5 ml. of inhibiting factor. To each of these solutions (to be used for coating) 1·5 ml. Tyrode solution was added. Contact of the serum–Tyrode mixture with uterine segments was done at 0–5° C. (that is, surrounded by crushed ice) for 1 hr. with air bubbled through the mixture throughout the period of contact.

The coated uterine segments were then used in a Schultz–Dale bath[4-6]. The antigens used to release

the reactions were supernatant solutions obtained from 20 per cent suspensions of carcinoma and melanoma tissues in isotonic sodium chloride, after removal of the sediments obtained at 14,000 r.p.m. The Tyrode solution used has half-strength calcium and ten times the normal amount of magnesium (sodium chloride, 9·0 gm.; potassium chloride, 0·20 gm.; calcium chloride, 0·05 gm.; magnesium chloride, 0·10 gm. (of crystalline magnesium chloride use 0·21); glucose, 1·00 gm.; sodium bicarbonate 1·00 gm.; sodium dihydrogen phosphate, 0·05 gm.; demineralized distilled water, 1 l.).

A corresponding normal antigen also used to release the reactions was prepared in the same way from several normal tissues (œsophagus, stomach, colon, lung). These normal tissues, which were obtained from a young victim of a car accident at autopsy, were pooled.

The results of this experiment (shown in Table 1) indicate the presence of two types of antibodies to tumour antigens: (1) those antibodies inhibited by normal inhibitor and present in the serum from the leukoplakia case: (2) those antibodies not inhibited by normal inhibitor found in the serum of the patient with active melanoma.

The finding that specific desensitization is possible to carcinoma antigens indicates the antigen–antibody basis of this reaction.

In the other experiments shown in Table 2 sera from 26 individuals with benign and malignant tumours were pooled according to the nature of the tumour, the state of tumour spread and the result of my tumour skin test[7,8] as follows: (1) Benign tumours—tumour skin test +, mean age 39·8 (4 individuals). (2) Carcinoma—early localized—tumour skin test +, mean age 60·3 (3 individuals). (3) Carcinoma—stage of local extension—tumour skin test +, mean age 47·5 (6 individuals). (4) Carcinoma—stage of metastasis—tumour skin test + mean age 54·2 (5 individuals). (5) Carcinoma—stage of metastasis—tumour skin test –, mean age 63 (4 individuals). (6) Carcinoma—cure (survival beyond 5 years)—tumour skin test –, mean age 69 (4 individuals).

These various pooled sera were then fractionated with ammonium sulphate into the following fractions: 33, 50 and 66 per cent. The precipitate in each case was dissolved in isotonic sodium chloride and brought to the original volume of the serum. Each serum fraction was then dialysed against running tap water, distilled water, sodium chloride 1 per cent, and phosphate buffer (sodium chloride, 6·8 gm.; sodium hydrogen phosphate, 0·81 gm.; potassium dihydrogen phosphate, 1·04 gm.; distilled water, 1,000 ml.: *p*H 6·8). The various fractions were then used for *in vitro* coating of uterine segments in the presence or absence of inhibiting factor from a normal blood donor as in the previous experiment.

The inhibiting factor was isolated by the following procedure: to the supernatant after the extraction of 66 per cent fraction, 2*N* sulphuric acid in 50 per cent ammonium sulphate was added slowly with mechanical stirring until the *p*H became 4·8. The precipitate was separated by centrifugation for 45 min. at 10,000 r.p.m. and discarded. The supernatant was then saturated with crystals of ammonium sulphate with continuous mechanical stirring for 1–2 hr. This was left over-night and then centrifuged for 45 min. at 10,000 r.p.m. The supernatant was discarded. The precipitate was dissolved in isotonic sodium chloride solution enough to bring it back to the original volume of serum. It was then dialysed in the same way as the other blood fractions from the diseased sera.

The coated uterine segments were then used in the Schultz–Dale test. To trigger the anaphylactic reactions, tissue and serum antigens obtained from normal and tumorous subjects were used, as well as various amino-acids and other key substances (such as deoxyribonucleic acid, adenylic acid, thymine, purine, pyrimidine, etc.).

Earlier work[9] has demonstrated the presence of antibodies to amino-acids (*a–a* antibodies) and antibodies to other key substances (*k–s* antibodies) in the sera of patients with cancer. An attempt was made in these experiments to see whether the inhibiting factor is effective in inhibiting *a–a* and *k–s* antibodies as well as antibodies to tissue and serum antigens.

The resulting specific anaphylactic reactions were then compared to the contraction of the same uterine segment when 10γ of histamine were added to the bath. This ratio of the specific contraction to that of histamine, that is, the contraction index, was further multiplied by 1,000 to obtain contraction index 1,000.

A ratio of inhibition was obtained by dividing the mean contraction index in the presence of normal inhibitor by the mean contraction index in the presence of Tyrode solution. The effect of inhibiting factor from a normal subject on the fixation to the uterine segments of antibodies, found in the various fractions from pooled sera of patients with tumours, is shown in Table 2. It is apparent from this Table that most of the antibody globulins studied are amenable to the inhibiting action of inhibiting factor (that is, preventing the antibody fixation to the uterine segment) as evidenced by inhibition ratios less than 1·0. Other antibody globulins, however, are not inhibited by inhibiting factor. Instead, a reversal seems to take place so that these antibodies are more fixed to the uterine segments in the presence of inhibiting factor. Thus all the globulins in the 50 per cent fractions could be inhibited as indicated by inhibition ratios less than 1·0 (the lowest value being that of a carcinoma cure pool).

Of the antibody globulins precipitated at 33 per cent only one out of the three fractions tested are inhibited by inhibiting factor (namely, that of carcinoma metastatic, tumour skin test +). The other two 33 per cent fractions from carcinoma local and carcinoma local extension show a reversal of inhibition in the presence of inhibiting factor indicating an abnormality of these latter two antibodies.

Of the antibody globulins precipitated at 66 per cent three out of the four showed inhibition by inhibiting factor (namely, those from fractions studied from carcinoma—local, carcinoma—metastatic tumour skin test +, carcinoma—metastatic tumour skin test −). The fourth serum fraction, representing antibody globulins precipitated at 66 per cent and obtained from the carcinoma—local extension pool, showed a marked reversal of inhibition to inhibiting factor (inhibition ratio being 5·11).

All the *a–a* and *k–s* antibodies studied seem to be amenable to inhibition by inhibiting factor. Again, those associated with the 50 per cent fraction seem to be more amenable to inhibition by inhibiting factor than those associated with the 66 per cent fraction.

These results demonstrate the presence of an antibody inhibitor in normal serum capable of inhibiting the fixation of antibody globulins to smooth muscle in the Schultz–Dale test. This same inhibitor is also capable of inhibiting the flocculation of normal globulins in the presence of cephalin–cholesterol–ether emulsions.

In some stages of cancer, inhibiting factor is capable of inhibiting antibodies associated with certain serum fractions, while in other stages, inhibiting factor is incapable of inhibiting antibodies associated with certain serum fractions. In these latter cases there seems to be a reversal of function so that even a normal inhibiting factor will result in increased, rather than decreased, fixation of antibodies to smooth muscle.

Other than this immunological defect in antibodies, found in certain serum fractions in cancer, there seems to be a defect in the inhibiting factor itself found in cancer sera. Evidence for this finding will be presented elsewhere.

I believe that this new concept of antibody inhibitor will prove to be not only of academic interest but also of assistance in allergic diseases, auto-immune disease and in the study of the ageing process and cancer.

A BIVALVE GASTROPOD

By Dr. L. R. COX, O.B.E., F.R.S., and Dr. W. J. REES
British Museum (Natural History), London, S.W.7

THE recent discovery of a remarkable mollusc, described as *Tamanovalva limax* gen. et sp. nov. by S. Kawaguti and K. Baba[1], calls for special notice, as this organism, while undoubtedly a gastropod, possesses a bivalve shell ; it is therefore of considerable interest to malacologists who are concerned with the possible origins of bivalve molluscs.

This unique type of gastropod, of which 200 or more specimens have been found, occurs in the sublittoral zone at Bisan Seto on the Inland Sea of Japan. The largest shells are 7 mm. long. The main features of the animal are :

(1) A slug-shaped head–foot mass which can be protruded from the shell and extends well to the front of it when the animal is crawling ; it can be completely withdrawn between the two valves, which close as in a lamellibranch. The foot is narrow and has a flat sole which can be folded longitudinally along the median line.

(2) Two stout rhinophores and two small lobiform oral tentacles on the well-developed head, and eyes which lie close together on a small median projection some way from its extremity.

(3) A radula of the sacoglossan type, in which only one tooth is in operation at a time, when the animal is feeding on its host plant (the alga *Caulerpa*).

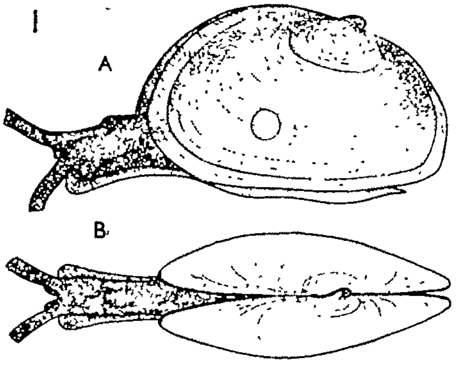
(4) A male genital aperture with penis, located far forward on the right side of the body, just behind the head.

(5) A bilobed mantle open along the ventral margins.

(6) A single gill, formed of a series of thin lamellæ as in the sacoglossan genera *Oxynoe* and *Lobiger*, and situated under the right mantle lobe.

(7) The anus opening into the mantle cavity well to the rear.

These structures and others that need not be mentioned are indicated in Figs. 1 and 2. There are no



Figs. 1*a*, *b*. *Tamanovalva limax* *a*, lateral view from left; *b*, dorsal view: note the rhinophores, eyes and protoconch (× *c*. 6·6) (After Kawaguti and Baba)

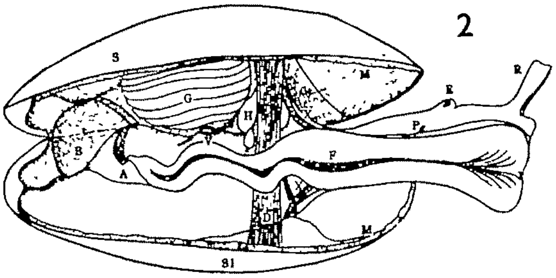


Fig. 2. *Tamanovalva limax*. ventral view (× 8). *A*, anus; *B*, hypobranchial gland; *D*, adductor muscle; *E*, eye; *F*, foot; *G*, gill; *H*, heart; *M*, mantle edge; *P*, penis pore; *R*, rhinophore, *S*, right valve of shell; *Sl*, left valve of shell, *V*, vaginal pore; *X*, head retractor muscle. (After Kawaguti and Baba)

siphons and no parapodia. The nervous system is not described.

The most remarkable feature is the shell, consisting of two valves which are equal in size and shape except for a small helicoid spiral structure at the apex of the left valve. There is a single well-developed adductor muscle which connects the two valves of the shell slightly in front of the middle of its length. The valves are joined along the hinge-line by an 'invisible' (? transparent) ligament; but there are no hinge-teeth.

Eggs are laid in sausage-shaped masses about 10 mm. long. The developing embryo passes through trochophore and veliger stages, and when the veliger hatches out it has a bilobed velum, a helicoid shell and an operculum. It is the larval shell that is preserved, as a protoconch, at th eapex of the left valve of the adult shell; it appears to be sinistrally coiled although the animal is dextrally organized (a feature of the typical opisthobranch protoconch)

The authors conclude that *Tamanovalva* is an opisthobranch gastropod belonging to the order Sacoglossa, as shown particularly by its slug-like body with two stout rhinophores and the nature of its radula. In view of its remarkable bivalve shell they have placed it in a new suborder Tamanovalvacea.

That this animal is a gastropod is indisputable, and its reference to the order Sacoglossa seems well justified. The opisthobranchs are now considered to be the most advanced sub-class of the Gastropoda, and many have contrived to counteract the disadvantages of torsion and asymmetry possessed by their prosobranch ancestors by the acquisition of secondary symmetry, of which *Tamanovalva* surely provides a further and most striking instance. It is to be interpreted as an evolutionary experiment in a sub-class not represented among the earlier known gastropods and in an order of which no fossil representatives have yet been recognized. The mere fact, however, that it demonstrates the possibility of a bivalve and almost symmetrical shell becoming developed in a normally univalve group lends support to the theory that the Bivalvia (Lamellibranchia) were derived originally from primitive univalve molluscs. Whereas, however, it has been supposed that this event involved the bending and hinging of a symmetrical, cap-like shell along its median line and the fusion of pallial muscles to form the two adductor muscles[2], the origin of the second valve and of the adductor muscle of *Tamanovalva* cannot be satisfactorily discussed until the post-embryonic ontogeny of this form has been investigated. It would appear that the protoconch-bearing left valve represents the original univalve shell and that the second valve is an extension which presumably arises by bilobation of the mantle at a relatively early stage in ontogeny (probably at the time of metamorphosis) and becomes hinged. Being quite independent of the foot, it clearly cannot arise from the operculum, which presumably, as in most other opisthobranchs, atrophies at an early stage in development.

Kawaguti and Baba refer briefly to *Edentellina* Gatliff and Gabriel[3], a supposed lamellibranch which, like their new genus, is characterized by the presence of a small coiled larval shell at the tip of one valve; but they consider it to be quite distinct. We are by no means convinced about this. The type-species of *Edentellina*, *E. typica*, was first discovered along the coast of Victoria and has since been found off South Australia and Western Australia. A second species, *E. corallensis*, dredged off Queensland within the Great Barrier Reef, has been described by Hedley[4], who at the same time has also re-described the type species. It seems significant that, according to that author, *E. typica* "lives in shallow water a little below the level of low tide" and that he had "commented on the absence from *Edentellina* of characteristic pelecypod features and suggested that possibly it might be the internal shell of a tectibranch" (tectibranchs are opisthobranch gastropods).

Hedley's figures of *E. typica*, which are more satisfactory than the rather poor photographs that illustrated the original description of the species, represent a small shell closely resembling *Tamanovalva* in shape. Although identified as a right valve from its outline (on the assumption that it belonged to a lamellibranch), the valve bearing the coiled larval shell at its tip is very similar to the corresponding valve (known to be the left one) of the Japanese form. In the original description of *E. typica* the shell was described as being without hinge-teeth, but afterwards, when better specimens were obtained, a small tooth-like structure was detected in both valves. Similar but possibly more obscure structures may have been overlooked in the Japanese species. The position of the adductor scar or scars has not been observed in *Edentellina*, while Hedley's statement that the soft parts of the animal are unknown appears still to hold good. It is, therefore, now all the more desirable that a special search for living specimens should be made in Australian waters, to ascertain whether or not this is a gastropod genus synonymous with *Tamanovalva*.

There is a further point, of special interest to palæontologists. As pointed out in Hedley's paper, a rare species found fossil in the Eocene of the Paris Basin appears to be a representative of *Edentellina*. It was known to Deshayes, who had assigned the

MS. name *Ludovicia squamula* gen. et sp. nov. to it, but was first described by Cossmann in 1888[5], by which time the name *Ludovicia* had already been published in connexion with an entirely distinct organism. The Paris Basin fossil is a small, thin-shelled bivalve of the same general trapeziform shape as *Edenttellina* and *Tamanovalva*, and young specimens have, at the tip of the left valve, a small spiral larval shell which is later lost. Although he included it in the lamellibranch family Galeommidae, Cossmann remarked, "j'aurais pu croire qu'il s'agissait d'un gastropode". If it is accepted as an *Edenttellina*, and if the latter proves to be identical with the newly described Japanese genus, we shall know for the first time that the opisthobranch order Sacoglossa existed so long ago as the Eocene.

The authors' full report on the remarkable aberrant form described in their paper will be eagerly awaited.

THE SECONDARY PAIRING OF BIVALENTS WITH GENETICALLY SIMILAR CHROMOSOMES

By DR. RALPH RILEY

Plant Breeding Institute, Cambridge

IN some allopolyploid plants, at first metaphase of meiosis, the bivalents are not randomly distributed but occur together in pairs or groups. This secondary pairing has been assumed to take place between bivalents composed of genetically similar pairs of chromosomes[1,2], but this assumption has apparently never been tested. Material suitable for such a test can, however, now be produced in the allohexaploid common wheat (*Triticum aestivum* $2n = 6x = 42$), in which secondary pairing may be occasionally observed.

The material used in the present investigation was developed from three parental lines in the variety Chinese Spring, generously supplied by Dr. E. R. Sears. These had chromosomes III, XII and XVI, in turn, represented by a pair of telocentric chromosomes for one arm, the other arm being completely deficient. Chromosomes III, XII and XVI are homœologous[3], that is, genetically equivalent chromosomes, belonging respectively to the *B*, *A* and *D* genomes derived from the original diploid ancestors of wheat[4].

The three lines were crossed together in pairs to produce *F*1's with one normal and one telocentric chromosome for each of two pairs. Thus, in the cross between the line with chromosome III telocentric and the line with chromosome XII telocentric, the hybrid had one telocentric member of the III and of the XII pair, and one normal member of each pair.

Meiotic pairing between the normal and telocentric chromosomes led to the formation of heteromorphic, rod-shaped bivalents, since chiasma-formation could take place only in one arm. The heteromorphics were readily recognizable in meiotic preparations, so that the relative positions of the two bivalents at first metaphase could be recorded.

The preparations analysed were Feulgen-stained squashes of pollen mother cells from anthers fixed acetic alcohol. Only cells having strictly linear arrangements of chromosomes were scored (Fig. 1), and the scoring recorded the number of bivalents which intervened between the two recognizably heteromorphic pairs. This method is artificial in that a structure which was originally two-dimensional, the metaphase plate, is represented as one-dimensional. However, it seems unlikely that squashing resulted in systematic distortions of the relative spacings of bivalents on the original plates. Moreover it should be indicated that the score of the number of bivalents intervening between the heteromorphic pairs is merely a measure of the degree of separation, and does not represent the number of bivalents by which they were separated on the original plate. With these reservations, however, the technique of recording seems satisfactory.

The data derived from scores of the three types of *F*1's with two heteromorphic bivalents are recorded in Table 1. There are no significant differences between the three distributions (III/XVI – III/XII, $\chi^2_{(14)} = 24{\cdot}56$, $P = 0{\cdot}1$–$0{\cdot}5$; III/XVI – XII/XVI, $\chi^2_{(15)} = 19{\cdot}03$, $P = 0{\cdot}3$–$0{\cdot}2$; and XII/XVI – III/XII, $\chi^2_{(14)} = 18{\cdot}86$, $P = 0{\cdot}2$–$0{\cdot}1$), so the data have been summed. The summed distribution falls off steeply from a clear maximum of cells with the heteromorphic bivalents adjacent, to minimum frequencies with the heteromorphics at opposite ends on the plate. The observed distribution has been tested against that expected from the random alignment of bivalents. This may be calculated from the generalized formula $\frac{2(n-1-r)}{n(n-1)}$, where n is the total number of bivalents and r is the number of intervening bivalents, for which I am indebted to Dr. W. F. Bodmer. The random distribution is a straight line which in the present instance runs from a frequency of 0·0952

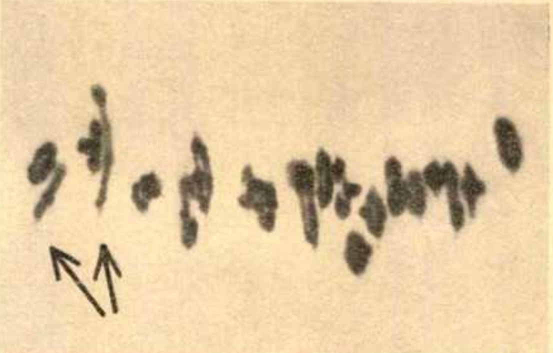

Fig. 1. First metaphase of meiosis in a plant of *T. aestivum* with one telocentric member of both the chromosome III and XVI bivalents. There is one intervening bivalent between the heteromorphic bivalents III and XVI, which are arrowed. (× 1,250)

Total	123	174	122	412	412·00	88·95

$\Sigma\chi^2_{(17)} = 88·95$; $P = < 0·001$

* Classes summed to increase the value of the expected.

with no interveners to 0·0048 with 19 interveners (Fig. 2).

There is a marked and highly significant deviation of the observed distribution from random ($\chi^2_{(17)} = 88·95$, $P = < 0·001$), and the largest single deviation is in the class with no intervening bivalent. Indeed, when the ratio of observations of the combined classes 1 to 19 : 0 is tested against random, the deviation is highly significant ($\chi^2_{(1)} = 56·51$, $P = <0·001$). Thus the major disturbance of the random distribution results from the heteromorphic bivalents occurring together too frequently.

If this represents secondary pairing, in the present experimental situation the apparent attraction between the marked homœologues may well have been affected by the deficiency of an arm from the telocentric member of each pair. If genetically corresponding arms were missing from the marked pairs, the amount of structurally similar material would be reduced, depending on the relative lengths of the arms of each chromosome, by about a quarter. Similarly, if the arms missing in each pair were not genetically equivalent, there would be only half the normal amount of structurally similar material. Consequently, if pairing depends on the degree of structural similarity, results based on pairs with telocentric members may under-estimate normal attraction.

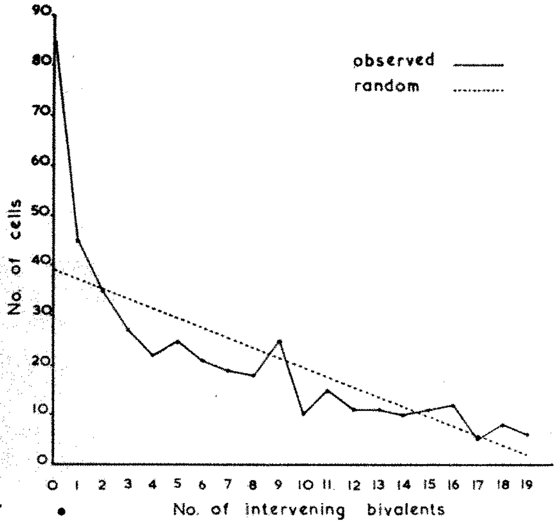

Fig. 2. Observed and random distributions of cells with the heteromorphic homœologous bivalents separated by 0–19 unmarked bivalents

Also the degree of secondary pairing might have been diminished because the marked bivalents were always rods, and rod bivalents probably move less freely than rings during the metaphase congression. Moreover, wheat is a hexaploid in which secondary pairing is ideally possible between all three bivalents involving chromosomes III, XII and XVI. However, in the material so far available, only two of these pairs have been simultaneously recognizable ; consequently the influence of the unmarked pair could not be determined. The excess of the class with one bivalent intervening may, however, be due to the separation of the marked pairs by their unmarked homœologue.

The excess of the combined classes with 17, 18 and 19 interveners may reflect a slightly non-random component in the arrangement of rod bivalents. Possibly they were more often at the periphery of the original plate, or their positions may have influenced the orientation of the plate on squashing. However, the majority of adjacent heteromorphic bivalents were in the interior rather than at the ends of the plates, so that this factor has probably not greatly influenced the recorded frequency of adjacent pairs. In subsequent work with marked non-homœologous as well as homœologous pairs, and in material with all three homœologues marked, this problem may be clarified.

Nevertheless, despite the intrusion of other disturbance, the considerable excess of immediately adjacent homœologous pairs seems to be reasonable evidence that secondary pairing brings genetically similar bivalents together, as had been supposed. If this is so, homœologous pairs must be attracted together following the wide dispersal of bivalents throughout the nucleus during diakinesis. However, the chances of secondary association very likely depend upon the relative proximities of homœologues during diakinesis. In wheat there are probably zygotene attractions between all six homœologous chromosomes but, in the presence of chromosome V, there is complete synapsis only between homologues[5]. If as a consequence of zygotene attractions homœologous bivalents are neighbours in early prophase, they are not likely to be so widely separated at diakinesis as non-neighbours, so that secondary pairing at metaphase will readily follow.

Evidence of secondary pairing between bivalents III, XII and XVI is a useful supplement to the demonstration of similarity in their genetic activity[3]. It is a further indication of the evolutionary proximity of these three chromosomes, and indeed of the genomes of which they are part. The extent of genetical and structural triplication of chromosomal material of wheat is thus re-emphasized in a way which re-asserts the significance of the genetic regulation causing wheat to form only bivalents, and no multivalents, at meiosis.

PHYSICS

Surface-controlled Bulk Conductivity in Organic Crystals

In an earlier paper[1] experiments were described which demonstrated hole injection from unexcited and optically excited electrode layers into an adjacent anthracene crystal, resulting in a large increase in the current passing through the bulk of the crystal. In the present communication, the interaction between an optically excited anthracene crystal and its adjacent electrode is reported.

The experimental techniques used have been described in detail elsewhere[2,3]. The general procedure was to use an electrolyte as the electrodes for thin (10μ) single crystals of anthracene. The incident light passed through the electrolyte before striking the crystal face. The current through the crystal was measured with $1M$ sodium iodide and $1M$ sodium chloride solutions in contact with the illuminated side of the crystal, using 3650 Å. light which was transmitted by the electrolyte but completely absorbed by the anthracene.

* $i+$ and $i-$ refer to currents measured when the polarity of the side illuminated by light was positive and negative respectively.
† Note change in scale.
The side illuminated by the light is listed at the top of each column in the table.

The experimental results are given in Table 1. The most interesting result was that the magnitude of $i+$ when the illuminated side of the anthracene was in contact with sodium chloride solution (column 6) was 13 times that of $i+$ when this side was in contact with sodium iodide solution (column 5). The current $i-$ did not change much.

It was also noted that the ratio $i+/i-$ in the case shown in column 6 was 285 as compared with a ratio of 7 in the case shown in column 4. The large value of $i-$ in column 4 was felt to be due in most part to an effect of fluorescent light on the anthracene–sodium chloride electrode face not directly illuminated. Scattering effects were ruled out by shielding the unilluminated face. Using identical sodium iodide electrodes, the ratio $i+/i-$ at 50 V. was 68 (column 3). The latter experiment was repeated with no change other than shifting the illumination from one face of the crystal to the opposite face. The ratio $i+/i-$ was 29 (column 5), indicating some crystal asymmetry. The change from sodium chloride to sodium iodide in the electrolyte at the unilluminated side decreases the $i-$ current, however, by a factor of 8, whereas the $i+$ current is almost unchanged (compare columns 3 and 4).

This dependence of $i-$ on the nature of the electrolyte in contact with the crystal face indicates that at least part of the current measured with the illuminated side negative is due to an interaction at the unilluminated electrode which produces positive holes at that face. The total $i-$ current would, therefore, be made up of the flow of these holes from the face not directly illuminated as well as electrons from the illuminated face. On this basis, the flow of electrons in $i-$ in the case shown in column 6 must be less than 0·3 per cent of $i+$.

In all cases, the photocurrents were almost saturated at 50 V. or lower. The dark current did not exhibit saturation.

The quantum efficiency for the photocurrent when the illuminated face of the crystal was in contact with sodium chloride solution was one carrier liberated into the anthracene crystal for thirty quanta falling on the face of the anthracene. In the case where the illuminated face was in contact with sodium iodide solution, the quantum efficiency was one carrier liberated into the anthracene for 390 quanta falling on the face of the anthracene.

In general, these results may be understood by assuming that the observed photocurrents are a result of the creation of an exciton by the light absorbed in the anthracene and its subsequent diffusion to the adjacent electrode, where it undergoes a dissociation into an electron and a positive hole. The latter then moves through the anthracene under the action of the electric field. Any event which will quench the exciton or inhibit its subsequent dissociation will diminish the photocurrent. Apparently such quenching occurs at the electrode by the I^- and its quenching action is greater than that of the Cl^-.

A more complete discussion of these results will be given shortly.

The work of Mr. Peter Gordon, who made most of these measurements, is greatly appreciated.

Grateful acknowledgment is made of the assistance of the Office of Naval Research (*NONR* 285(41)) in this work and of the Air Force Cambridge Research Center, Contract *AF*19(604)–3888.

Emission Spectroscopy with Infra-Red Double-Beam Spectrophotometers

SOME time ago, K. A. Fischer and G. Brandes[1] demonstrated that it is possible to obtain useful emission spectroscopic data with an infra-red double-beam spectrophotometer, if the sample placed in the beam path of the spectrophotometer is warmed up with a closed sample beam shutter. Instead of the quotient of the radiation intensity passed by the object and of the unattenuated radiation intensity, the instrument now scans the quotient of the inherent radiation intensity of the object and of the reference beam intensity.

The sensitivity of this method can be increased 100 times, if the intensity of the reference beam is attenuated by means of a Venetian shutter by the same factor. Thus it is possible to record also the relatively weak emission maxima of moderately heated gases.

Fig. 1 shows the emission spectrum of ammonia, heated up to 160° C., between 9 and 12μ, recorded with a ten-fold reference beam attenuation. The thickness of the ammonia sample was 5 cm. The spectrum was recorded with a Model 21 Infra-red Spectrophotometer of Bodenseewerk Perkin-Elmer and Co., GmbH. The attenuation of the reference beam was effected by a reference beam attenuator designed as an accessory to this instrument, the object being warmed up in a heatable gas cell, which likewise constitutes a usual spectrophotometer accessory though serving other purposes otherwise. The spectral dispersion was effected with a sodium chloride prism; the slit-width was controlled with the 'slit programme 800'. This slit programme provides a slit-width of 55μ at a wave-length of 10μ. Because of the low energy striking the thermocouple, the instrument was operated with maximum amplification, maximum time constant and a scanning speed of 5×10^{-4} μ/sec. The spectrum distinctly shows the emission maxima assigned to the absorption bands of the ammonia. Fig. 2 shows the absorption spectrum of the same sample, which was scanned with the same slit programme, however, without reference beam attenuation. It becomes obvious that the frequency conformity of the emission and absorption maxima has been realized quite well. The intensity ratios between the individual maxima are, however, considerably changed.

Rotational Analysis of the $C^2\Pi - X^2\Sigma^+$ System of CaCl

ALTHOUGH many of the electronic band-systems of the monohalides of Group II*A* are readily observed in emission and absorption, little is known about the properties of these molecules, other than their force constants and the positions of their lower-lying electronic energy states. Only one complete rotational analysis, of the system $A^2\Pi_1 - X^2\Sigma^+$ in BeF has yet been given[1].

In many cases, the rotational structure is, through the near equality of B-values, too close to be resolved, but new photographs on a 6·65-m. grating spectrograph suggest that analyses of some systems will be possible. One such system is $C^2\Pi - X^2\Sigma^+$ in CaCl, which may conveniently be observed in absorption. We have been able to analyse the 0,0 band, and the shorter wave-length sub-bands of the 1,0 and 0,1 bands. The upper state is sufficiently close to Hund's case *a* for the two sub-bands to be treated independently to give effective values of B' and D'. The Λ-type doubling, which is negligibly small in the shorter wave-length sub-bands, but observable in the longer wave-length components, shows that the C state is $^2\Pi_{\text{reg.}}$, presumably $\cdots (w\pi)^4(v\pi)$, $^2\Pi_r$. An earlier, incomplete analysis[2] of this system is incorrect. The constants obtained in the present analysis are summarized in Table 1.

Table 1. SUMMARY OF CONSTANTS FOR THE $C^2\Pi_r - X^2\Sigma^+$ SYSTEM OF $Ca^{35}Cl$

State	T_0	$\Delta G_{0,1}$	B_0	10^4	$10^7 D$	r_e, Å.
$C^2\Pi_{3/2}$	26,557·80	333·86	0·14268	7·47	$1{\cdot}0_0$	$2{\cdot}516_0$
$C^2\Pi_{1/2}$	26,481·82		0·14216		$1{\cdot}0_3$	
$X^2\Sigma^+$	0	367·53	0·15156	$7{\cdot}8_2$	1·0	$2{\cdot}439_0$

It is of some interest to compare the internuclear distances in the ground-states of the monohalides with those found in the dihalides[3]. Figures are given in Table 2. They suggest that the distances in the monohalides are about 3 per cent shorter than in the corresponding dihalide.

Table 2. INTERNUCLEAR DISTANCES (REFS. 1 AND 3)

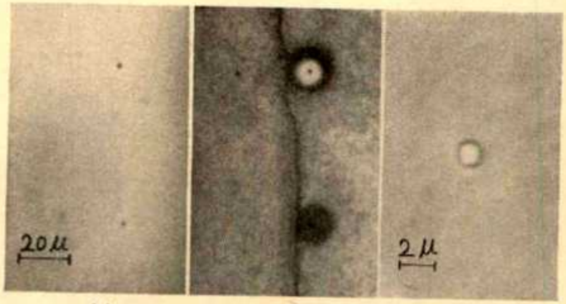
Dark Blue Ring developed by Electron Bombardment in Rock Salt

WE have recently studied the effect of electron bombardment on rock salt crystal obtained from the Halle Company in Germany. It was found that the blue or colloidal coloration was produced on the surface of the specimen bombarded with electrons at high temperature[1]. In the course of the experiments we have also observed that the dark blue rings or circles were scattered on the coloured surface. In this communication we shall be concerned mainly with the behaviour of these rings or circles.

Bombardment was performed as follows. The cleaved specimen was annealed for 60 min. at elevated temperature *in vacuo* and then bombarded with electrons for 15 min. at the same temperature. The bombarding voltage and current density were 18 kV. and 80 μamp./cm.² respectively.

Figs. 1*a* and *b* show the same field of vision of the specimen before and after bombardment, and Fig. 1*c* gives a magnified picture of the small point shown in Fig. 1*a*. These observations show that the rock salt as received contained a large number of small cubic cavities within the crystal (about 10^7/c.c.); and the centre of the dark blue ring corresponds to a cavity just beneath the surface and the centre of the circle to one which is somewhat deeper in the crystal. The edges of this cavity are parallel to the {100} planes of rock salt.



(*a*) (*b*) (*c*)

Fig. 1. Dark blue ring and circle developed by electron bombardment. (*a*) Before bombardment; (*b*) after bombardment (*T* = 300° C.); (*c*) magnified photograph of the small point in (*a*)

The changes in the ring pattern are shown in Fig. 2 as a function of temperature during the bombardment. The diameters of both outer and inner circles of the rings increased with the rise of temperature, and at the same time, the dimension of each cubic pit at the centre also increased. At temperatures above 370° C., only large cubic pits were produced.

Further heat treatment of the ring after bombardment led to increase of the inner diameter with the rise of temperature, but the outer ring did not increase, and at about 450° C. it was bleached out entirely.

Apart from the dark blue ring or circle, we also observed the development of a coloured contour line as shown in Fig. 1*b*. Figs. 3*a* and *b* show matching surfaces of the cleaved specimen after bombardment; it can be seen that the matching of the contour lines was very good. Hence these contour lines are believed to indicate the sub-grain boundaries.

We are now investigating the mechanism of development of these peculiar types of coloration in

CRYSTALLOGRAPHY

Crystal Structure of Mellitic Acid

THE only published crystallographic data for mellitic acid, to the best of our knowledge, are those reported by Deverin[1]. According to his observations mellitic acid is dimorphic: rhombohedral when crystallized from aqueous solution at room temperature, and of an unidentified lower symmetry class when separated from hot aqueous solution.

We obtained large prism-shaped crystals from a hot solution in 50 per cent nitric acid. The crystals were orthorhombic, optically negative, elongated in *b*-axis direction, pseudo-hexagonal, with well-developed forms {100}, {102}, {010}, exhibiting a perfect cleavage parallel to (010). The crystals were not stable for long periods, especially not when irradiated by X-rays, but became opaque and eventually disintegrated in a white crystalline powder. We assumed at first that the loss of nitric acid as solvent of crystallization might be the cause of the disintegration, but the micro-combustion analysis showed that our specimens had been pure mellitic acid. The phenomenon has been, therefore, explained as a transition from the orthorhombic high-temperature modification to another of low temperature, probably identical to the rhombohedral modification, observed by Deverin. It is rather interesting that our orthorhombic crystals, obtained from nitric acid solution, were considerably more stable while in contact with the mother liquor. Therefore, all our X-ray diffraction measurements were carried out with the specimen sealed over a drop of the mother liquor in a Lindeman glass capillary.

The unit cell and space group were determined from the oscillation and Weissenberg diffraction photographs taken with copper $K\alpha$-radiation. The orthorhombic unit cell, which has the dimensions: $a = 16 \cdot 60$ Å.; $b = 8 \cdot 17$ Å.; $c = 19 \cdot 17$ Å., contains eight molecules $C_{12}H_6O_{12}$. The space group is $C^{10}_{2h} - Pccn$. All possible $0kl$, $k0l$ and $hk0$ reflexions were recorded with the help of an integrating Weissenberg goniometer. The relative intensities were determined from the multiple film photographs with the use of a microdensitometer. The ratio of the weakest to the strongest intensity of 1 : 16,000 was obtained.

The Patterson projection on the (010) indicated: (i) that the nolecules of mellitic acid formed layers parallel to the (010), (ii) that in the *b*-axis period two such mutually displaced layers were involved. The overlapping of these layers in the projection gave a vector map with an intricate hexagonal pattern which could not be interpreted satisfactorily. The arrangement of the molecules was then derived from the (100) and (001) Patterson projections. The molecules occupy positions on the diad axes so that the unit cell contains two symmetrically independent groups of four molecules which are defined in the International Tables[2] by the (*c*) and (*d*) sets of co-ordinates, respectively. The ambiguity in the orientation of the molecules toward the diad rotation axis was solved with the help of a trial-and-error procedure in which both the (010) vector map and the $h0l$ intensity data were considered. In this stage of the analysis it became evident that numerous possibilities for locating oxygen atoms would require tedious computational work of successive refinement. Therefore, a new direct method for the phase determination was elaborated by one of us[3] and applied to the sign determination of the structure factors $F(hk0)$ and $F(0kl)$. The electron density maps, computed on the basis of these signs, gave the first co-ordinates of oxygen and carbon atoms, which enabled an efficient refinement of the (010) electron density map, resulting in the complete elucidation of the structure. The final electron density map on the (010) is given in Fig. 1.

All carbon atoms of a molecule lie in a plane which is inclined to the (010) at not more than about two degrees. Each molecule is surrounded by six nearest molecules with the approaches in the direction of their carboxyl groups at the distance of $2 \cdot 62 \pm 0 \cdot 01$ Å. between oxygen atoms. This value for the oxygen separation between two carboxyls is evidence of a strong hydrogen bonding which links molecules together in an endless layer parallel to (010). A preliminary investigation by infra-red spectra confirmed roughly this hydrogen bond-length (Hadži, D., private communication). The next layer is derived in the same way but, in relation to the former, it is displaced along the *c*-axis by the amount of $z_2 - z_1 = 0 \cdot 151$, where z_1 and z_2 are the parameters of the centre of the two symmetrically independent molecules. The whole crystal structure of mellitic acid is thus built up by the alternation of these two layers with the separation of $1/2b$ between them (Fig. 2). Since the diad axis lies in the plane of the benzene ring and passes through two opposite carboxyl carbon atoms, the orientation of six carboxyls of one molecule is defined by four planes differently inclined to the plane of the benzene ring. The most inclined pair of carboxyls approaches the carboxyls of both upper and lower layer at the distance of $2 \cdot 68$ Å. between oxygen atoms. This approach may be accounted for by hydrogen bonding between layers. Such interlayer contacts occur three times less than the contacts within the layer, which explains the perfect cleavage parallel to the layer plane. Moreover, the contacts between

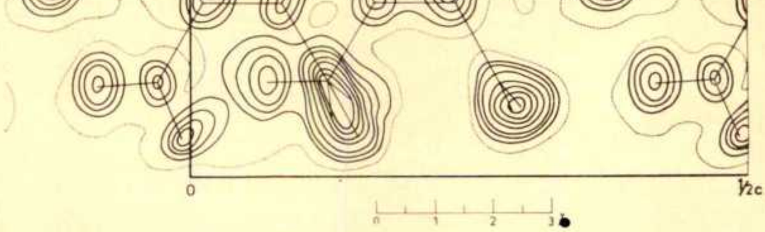

Fig. 1. The ($h0l$) electron-density projection of the crystal structure of mellitic acid. Contour interval, $2e.\text{Å}.^{-2}$; zero contour, dotted

carboxyls within the molecule itself occur at distances of 2·69, 2·71 and 2·75 Å. between oxygen atoms. Consequently, all oxygen atom contacts in the crystal structure are not essentially different, varying from 2·62 to 2·75 Å. If we assume, therefore, that the hydrogen bonding may be effectuated by all these contacts, then there are in the structure more hydrogen bonds than protons. This is possible only if a randomness of the proton positions is admitted. In favour of this assumption is also the symmetry of the carboxyls, since only one value of 1·23 ± 0·01 Å. for C–O distance has been found for all carboxyls and not only for those located on diad axis. The insignificant difference in length of the C–O bonds was previously established only for ionized carboxyls[4]. The symmetry of the carboxyl as well as a slightly shorter C–O bond found in the present case may be explained by the unique molecular structure of mellitic acid, which enables all carboxyls to be engaged in a hydrogen bond network throughout the crystal structure.

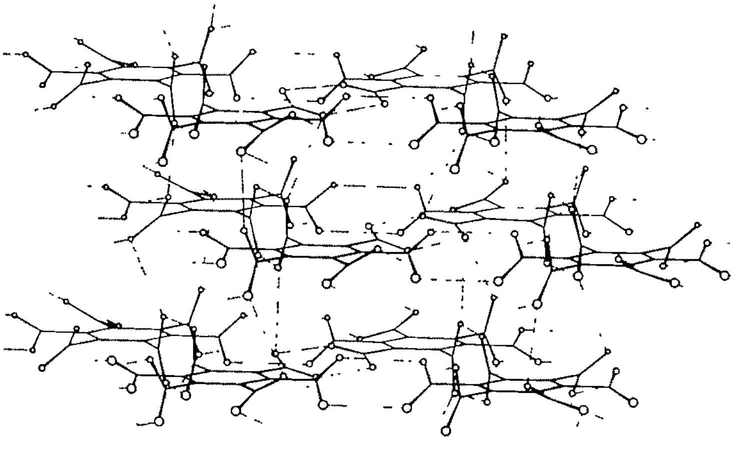

Fig 2. The layers of the crystal structure of mellitic acid as viewed in the direction of the *a*-axis. The separation between layers is 1/2*b*. The hydrogen bonds between oxygen atoms (circles) are shown by dotted lines

The more accurate determination of the bond-lengths has been prevented by overlapping of the atoms in the electron density projection. The three-dimensional Fourier synthesis as well as the difference synthesis is therefore anticipated. The C–C bond-lengths within the benzene ring as well as from it to carboxyl, obtained from the projections, are in good agreement with the previously reported data for this kind of compound, that is, 1·40 ± 0·01 Å., and 1·50 ± 0·01 Å., respectively. The reliability indices are: $R(h0l) = 0·12$; $R(0kl) \doteq R(hk0) = 0·13$.

We wish to thank Miss N. Katinčić for carrying out the synthesis of mellitic acid starting from xylene. We are also indebted to Mrs. I. Guštak-Mašek for the micro-analysis and to Mrs. G. Finžgar for valuable help in the computation.

Thermal Expansion of Triglycine Sulphate

Matthias, Miller and Remeika[1] were the first to observe that triglycine sulphate becomes ferroelectric below 47° C. The dielectric properties and the specific heat of this crystal have been studied through the transition temperature by Hoshino, Mitsui, Jona and Pepinsky[2]. The observed variation of the dielectric properties as a function of temperature in this crystal shows that the transition is of second order. Hoshino *et al.* concluded that the anomaly is not of the λ-type, since their specific heat – temperature curve showed only a hump. It was decided to investigate the thermal expansion of this crystal as it might throw some light on the nature of the transition.

Triglycine sulphate belongs to the monoclinic system. Wood and Holden[3] determined the unit cell dimensions and the optical properties of this crystal. The complete structure of the ferroelectric phase of this crystal has been determined by Hoshino, Okaya and Pepinsky[4]. The crystallographic axial system of these authors is used in this communication in designating the directions in this crystal. The thermal expansion of triglycine sulphate and its temperature variation have now been investigated both above and below the transition point by the interferometric method for the following directions in the crystal: (1) parallel to the *b* axis, which is also the axis of spontaneous polarization in the crystal, and (2) parallel to the *a* and *c* axes, and perpendicular to the *a* axis in the (010) plane.

The specimens used for the expansion measurements along these four directions were cut from different crystals of triglycine sulphate and the measurements were repeated several times for each direction.

The variation of the thermal expansion coefficient (α) with temperature (T) for these four directions is plotted in Fig. 1. The results are summarized as follows:

Along the *c* and *a* axes and perpendicular to the *a* axis, the crystal expands as it is heated up to the transition point, the expansion coefficient becoming larger and larger as the transition point is approached. At the transition point there is an abrupt reversal of the sign of the expansion coefficients, the crystal contracting along these directions above the transition point. The behaviour along the *b* axis is just the opposite. The crystal contracts on heating up to the transition point and thereafter expands in this direction.

From the continuous change in the dimensions of the crystal, it appears that the transition is of the second order. This result is in agreement with that reported by Hoshino *et al.*[2]. From the nature of the α versus T curves (Fig. 1) one has to infer that the anomaly is of the λ-type, which does not agree with the observations of Hoshino *et al.*[2] on the specific heat.

Ubbelohde and Woodward[5] have found that in Rochelle salt the direction of maximum expansion coefficient lies almost along the direction of the shortest hydrogen bond. From the structural data of Hoshino, Okaya and Pepinsky[4] and the present

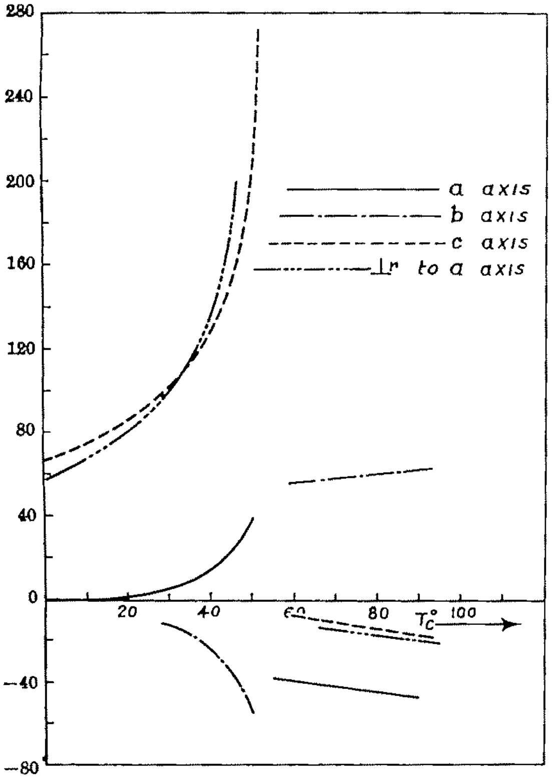

Fig. 1. α v. T curves for triglycine sulphate

results on the thermal expansion a similar conclusion could be drawn, namely, the direction of maximum expansion coefficient coincides nearly with the direction of the shortest hydrogen bond (length 2·438 Å.), which according to Hoshino *et al.*[4] is responsible for the dipole reversal mechanism.

The temperature at which the abrupt change in sign of α occurs has been observed to be slightly different for measurements along different directions, but all of them lie between 51° C. and 53° C., which is definitely higher than the value of the transition temperature of 47° C. reported by Matthias *et al.*[1] and Hoshino *et al.*[2]. It should be mentioned that all the measurements reported here were carried out while the crystals were heated. Taking measurements while the crystal was being cooled, it was found that the change in sign of α occurred at about 47° C. Preliminary evidence has also been obtained for thermal hysteresis in this crystal. Further investigations are under way to study the thermal hysteresis and a detailed report of the results will be published in due course.

I wish to express my thanks to Prof. R. S. Krishnan for his interest and to Dr. Vedam and Dr. Srinivasan for discussions. I also thank the former for suggesting the problem.

CHEMISTRY

Recrystallization of Amorphous Copper Sulphate Monohydrate

When copper sulphate pentahydrate is dehydrated in a vacuum at room temperature, the resulting product, of composition copper sulphate monohydrate, possesses no evident crystal structure as shown by X-ray examination[1]. When the amorphous product is heated, crystallization occurs as shown by the appearance of the X-ray lines of the crystalline monohydrate[2].

The changes which occur on heating can also be followed by investigating the changes in the electron spin resonance spectrum, since the spectrum of the paramagnetic copper ion is influenced by its environment in the solid which, of course, will change as crystallization occurs. The spectra were recorded on a 'Varian Model 4500' spectrometer. The curves in Fig. 1 are traces of the derivative of the absorption curve as recorded by this instrument.

Copper sulphate pentahydrate was ground to pass a 200-mesh sieve. Curve *F* illustrates the electron spin resonance spectrum on this powdered material. Curve *A* was obtained from a portion of this material which had been dehydrated in a vacuum desiccator over magnesium perchlorate until the composition corresponded to the monohydrate. The sample showed a very weak broad absorption. The extreme broadening was presumably due to the random environment of the paramagnetic copper ions in the amorphous material. When the material is heated, changes in the spectrum occur after an apparent induction period. Curves *B*, *C* and *D* indicate the

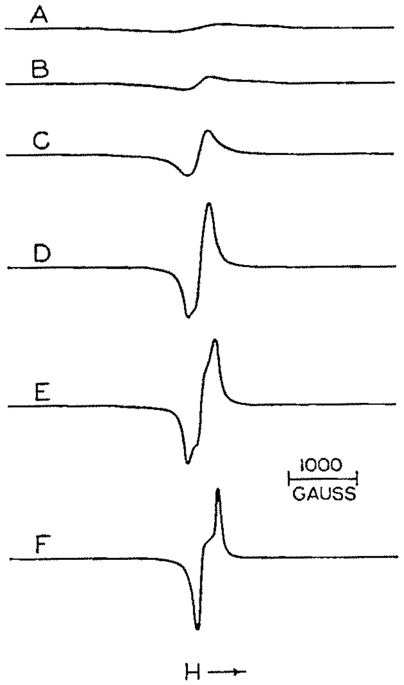

Fig. 1. Electron spin resonance spectra of copper sulphate hydrates. *A*, $CuSO_4.H_2O$ freshly prepared; *B*, $CuSO_4.H_2O$ heated 170 min. at 75° C.; *C*, $CuSO_4.H_2O$ heated 190 min. at 75° C.; *D*, $CuSO_4.H_2O$ heated 200 min. at 75° C.; *E*, Crystalline $CuSO_4.H_2O$ prepared at 110° C.; *F*, powdered $CuSO_4.5H_2O$.
Curves *A*, *B*, *C* and *D* were recorded at twice the amplification of curves *E* and *F*

traces obtained when the length of time of heat treatment of the sample at 75° C. was increased. With the recrystallization of the solid, the absorption narrows. Curve *E* is for a sample which was prepared and completely recrystallized at 110° C. A small amount of fine structure on the low-field side of the maximum is evident in curves *D* and *E*.

X-ray powder diagrams were taken at various stages of the recrystallization, using a General Electric recording X-ray diffraction unit. The material which gave the electron-spin resonance spectrum of curve *A* showed no diffraction lines. After heating, the X-ray diffraction lines of the monohydrate appeared.

It is interesting to note that the electron-spin resonance spectrum of a sample only partially recrystallized could not be simulated by the spectrum of a mixture of the amorphous monohydrate and the completely recrystallized compound. Even under higher amplification, the spectrum of sample *C* in Fig. 1 shows no evidence of fine structure on the low-field side of the maximum. A mixture of 19 per cent of the recrystallized monohydrate (sample *E*) and 81 per cent of the amorphous material (sample *A*), which gave the same overall intensity of absorption, very clearly showed fine structure. The very first stages of recrystallization do not appear to involve the formation of regions in the solid which yield the same electron-spin resonance spectrum as the completely recrystallized material of sample *E*.

Some Atomic Reactions by Absorption Spectroscopy

NORRISH and co-workers[1-3] have shown that vibrationally excited oxygen molecules are produced by flash photolysis of chlorine dioxide, nitrogen dioxide and ozone. These molecules are believed to originate in reactions of the type:

$$O + ClO_2 \rightarrow ClO + O_2^* \quad (1)$$

Combination of familiar atomic flame techniques[4,5] with absorption spectroscopy should enable such reactions to be studied directly. We have made observations of the reactions of atomic oxygen with ClO_2, NO_2 and O_3 in this way, at pressures of 0·1–30 mm. mercury. Similar studies have been made using atomic nitrogen and hydrogen in the cases of ClO_2 and O_3.

Atoms were produced from the molecular gas by electrodeless discharges (at 2,450 or 30 Mc./s.) and mixed with the reactant gas at one end of a reaction cell, 2 cm. in diameter and 30 cm. long, with quartz end-windows. Linear flow-rates through the cell were between 100 and 250 cm./s. The continuum from a high-pressure xenon source was focused through this cell, and viewed with a Hilger quartz, Littrow type, spectrograph. The extent to which atomic oxygen had reacted could be seen from the decrease in the green after-glow (caused by reaction of O with NO formed in the discharge from nitrogen impurities) when the reactant was added, and, in the case of atomic nitrogen, from the decrease in the Rayleigh after-glow. In most cases spectroscopic data were obtained at flow-rates such that these after-glows were almost extinguished, that is, at complete consumption of the atoms. Under these conditions weak flames were usually seen in the reaction vessel.

Some observations are summarized in Table 1.

Table 1. SPECTRAL OBSERVATIONS OF SOME ATOMIC FLAMES

Atom	Reactant		
	ClO_2	NO_2	O_3
O	ClO_2 removed ClO produced Red flame	NO produced	Red flame (weak)
N	ClO_2 removed ClO produced (weakly) Green flame	—	O_3 removed No NO Blue-white flame
H	ClO_2 removed No ClO or OH Green flame (weak)	Red flame	O_3 removed No OH Red flame (weak)

The sensitivity of the spectroscopic system can be judged from the fact that amounts of NO and NO_2 giving partial pressures of 0·01 and 0·10 mm. mercury respectively could be observed readily. The rotational temperature of the NO produced in the $NO_2 - O$ reaction was the same as the temperature of the reaction vessel. A tenfold increase in pressure by the addition of argon gave no new information. No evidence was found for the existence of vibrationally excited species.

A quantitative examination of the system is necessary to see what limitations might apply to the production and detection of vibrationally excited oxygen. By adding sufficient NO_2 to quench the after-glow in the products of the oxygen discharge[6], and making spectroscopic determinations of the NO molecules produced, the concentration of atomic oxygen was established to be 10 per cent of the gases from the discharge at 2 mm. mercury. Although the efficiency of O_2 in deactivating O_2^* is not known, one collision in 10^5 can be taken as reasonable in comparison with the efficiencies given by Norrish[3] for other molecules. If it is further assumed that all the O atoms form O_2^* by reaction (1) the total number of O_2^* molecules in the reaction vessel is calculated to be $3 \cdot 6 \times 10^{16}$ at 2 mm. mercury, or 0·6 per cent of all molecules present.

An estimate of the amount of the other product of reaction (1) can also be made in the case of ClO, for which radicals the rate constant for recombination has been determined[7]. It gives a total number of ClO radicals of $2 \cdot 7 \times 10^{16}$, or 0·4 per cent of the gas at 2 mm. mercury. Our failure to find O_2^*, while ClO was readily detected, may be due to: (*a*) a deactivation efficiency of O_2 greater than the estimated 1 in 10^5; (*b*) a smaller absorption coefficient for O_2^* than for ClO; or (*c*) O_2^* not being produced by reaction (1), which possibly requires metastable O atoms rather than the ground-state atoms given by our discharges. Similar reasoning can also be applied to the $NO_2 - O$ reaction, except that now the NO produced, since it is stable, reaches 10 per cent of the total gas.

Concentrations of atomic nitrogen were measured by titrating the active nitrogen with nitric oxide[8], and afterwards determining the amounts of NO by spectral absorption when the discharge was extinguished. At 20 mm. mercury about 1 per cent nitrogen atoms were produced. The disappearance of ClO_2 by reaction with N atoms, but only very weak ClO, and no NO absorption can be interpreted by a low rate of:

$$N + ClO_2 \rightarrow NO + ClO \qquad (2)$$

or by rapid subsequent disappearance of the products of this reaction. Lack of NO absorption in the reaction of N with O_3 can be explained as follows. When [N] is greater than $[O_3]$, the nitric oxide formed is destroyed rapidly by the excess of free atoms. On the other hand, when ozone is in excess it will react rapidly with NO (ref. 9).

The concentration of atomic hydrogen was not measured, but previous experience[10] with the same type of discharge indicates a concentration of about 10 per cent. Again, the decrease in ClO_2 absorption, without any OH or ClO absorption, can be taken as evidence that the initial attack does not produce these radicals or that their subsequent reactions are extremely rapid.

The ease of detection of small quantities of NO and ClO suggests that absorption spectroscopy could be a useful tool for studying kinetics in steady-state flow systems of this type. Moreover, the spectroscopic measurement of NO has proved to be very useful in determining the concentrations of oxygen and nitrogen atoms. The visible reaction flames suggest that a study of their emission spectra may provide information regarding the initial steps in these reactions.

Ionic Hydration in Mixtures of Strong Acids and Water

FROM Raman and nuclear magnetic resonance measurements the concentrations of species present in mixtures of strong acids with water have been evaluated[1-3].

These measurements show that each ionic constituent has a maximal concentration at a certain composition of the mixture. The existence of such maxima can be understood in terms of hydration of the ionic species present.

Consider the following reaction:

$$HA + n\,H_2O \rightleftarrows H^+(H_2O)_{n+} + A^-(H_2O)_{n-} \qquad (1)$$

$$n_+ + n_- = n$$

Application of the law of mass action to (1) gives:

$$a_{H^+(aq.)} \cdot a_{A^-(aq.)} = K_n \cdot a_{HA} \cdot a_{H_2O}{}^n \qquad (2)$$

where $a_{H^+(aq.)}$ and $a_{A^-(aq.)}$ denote the activities of $H^+(H_2O)_{n+}$ and $A^-(H_2O)_{n-}$, and n is the total number of water molecules bound to the ions H^+ and A^-. By differentiation of (2) and combination with the Gibbs–Duhem equation, it can be shown that the activity product of the hydrated ions will have a maximum at the concentration[4]:

$$X^s{}_{HA} = \frac{1}{1 + n} \qquad (3)$$

where $X^s{}_{HA}$ is the stoichiometric mole fraction of acid. The maximum will thus appear at the stoichiometric concentration corresponding to the assumed composition of the hydrated ions.

When considering concentrations of ionic constituents, the variation of their activity coefficients will be neglected. From the electroneutrality condition:

$$C_{H^+(aq.)} = C_{A^-(aq.)} \qquad (4)$$

and (2) it can be shown that, within the uncertainty of the variation of the ionic activity coefficients, condition (3) is retained for the location in the maximal concentration of A^-.

The maxima can be considered to arise from the competition of various hydration reactions with the formation of HA molecules. It can be stated that the weaker the acid the more will the maximal ionic concentration be displaced in the direction of pure water. In Table 1 a comparison is made between experiments and equation 3.

Table 1. COMPARISON OF MOLE FRACTION OF MAXIMAL IONIC CONCENTRATION WITH EQUATION 3

n	$X^s{}_{HA}$ (3)	$X^s{}_{HA}$ exp. NO_3^-	ClO_4^-	HSO_4^-
1	0·50		0·40–0·50 (ref. 2)	0·42 (ref. 3)
2	0·33			
3	0·25	0·26 (ref. 5)		
4	0·20	0·21 (ref. 2)		

As seen from Table 1, the maximum ionic concentration of NO_3^- appears in the range where there are 3–4 H_2O per H^+, NO_3^-, while maximal concentration of ClO_4^- and HSO_4^- are in the range where there is about 1 H_2O per H^+, A^-. That nitric acid behaves differently from the other two acids is due to its weaker dissociation. From the data of Redlich *et al.*[2] it is found that even at $X^s{}_{HNO_3} = 0·40$ there are more than four water molecules per mole of dissociated acid.

In the primary dissociation of H_2SO_4, the main hydrated ionic constituent is likely to be H_3O^+ (ref. 6). However, the displacement of the maximal ionic concentration from 0·50 to 0·42 implies that hydrated species other than H_3O^+ are also present. This further hydration can be taken into account. By assuming the formation of all possible hydrated ionic species, it can be shown that maximum concentration of the anion A^- will be located at $X^s{}_{HA} = 1/(1 + \bar{n}')$, where $\bar{n}'$ approximates the average number of water molecules bound to the ions H^+ and A^- (ref. 4). For $X^s{}_{H_2SO_4} = 0·42$ this gives $\bar{n}' = 1·40$. The same value for $\bar{n}'$ was obtained by an approximate method of finding $\bar{n}'$ reported elsewhere[6]. Using the values of $\bar{n}'$ given in ref. 6, it is also found that at $X^s{}_{H_2SO_4} = 0·42$ the free water practically disappears and becomes tied up as water of hydration. Now, Young *et al.*[3] have found that measurable amounts of sulphuric acid start to appear at this same concentration. It thus seems that molecules of sulphuric acid cannot appear until nearly all free water has been consumed.

The Sodium Silicate – Hydrogen Peroxide System

THE chemistry of silicic acid in solution is rather ill-defined[1] owing to the extremely weak nature of this acid[2] and its tendency to polymerize[3,4]. As there are many instances where hydrogen peroxide effectively prevents anionic polymerization[5,6], an attempt was made to investigate the hydrolysis of silicate ions in the presence of hydrogen peroxide by means of accurate conductivity[7] and *p*H measurements. For comparison, the same technique was applied to an identical series of solutions in the absence of hydrogen peroxide. Fig. 1 shows the results of the investigation on solutions which were 0·01 *M* in sodium silicate and, in the case of the 'peroxidized' system, approximately 0·1 *M* in hydrogen peroxide; sulphuric acid was 0·498 *M*.

The *p*H curve of the system sodium silicate–water (full lines) shows two changes: a weak one on addition of 4·75 ml. sulphuric acid and a strong change on addition of 9·3 ml. acid. The former change may be due to the reaction of the dihydroxy-*ortho*silicate ion[1–3] with hydrogen ions:

$$(SiO_2(OH)_2)^{2-} + H_3O^+ = (SiO(OH)_3)^- + H_2O \quad (1)$$

The latter change denotes obviously the completion of the neutralization reaction:

$$1OH^- + H_3O^+ = 2H_2O \quad (2)$$

the hydroxyl ions being those hydrolytically produced by sodium silicate. Corresponding changes in the conductivity curve of the same system are brought out by the interpolated point of intersection[8] *B* (equation 1) and point *D* (equation 2) respectively. The strong *p*H change (equation 2) seems to mask the final decomposition of the trihydroxy-*ortho*silicate ion to silicic acid, although some indication of the latter reaction is borne out by the shape of the conductivity curve near point *D*.

A similar picture emerges from the investigation of the sodium silicate – hydrogen peroxide system (dotted lines), with the difference that as the *p*H of the initial solution lies below 10·75 (owing to the consumption of hydroxyl ions by hydrogen peroxide in alkaline solution) the points *A* and *B* are absent. A comparison of the specific conductivities in the two systems for solutions containing 6–9 ml. sulphuric acid reveals the rather significant finding of higher conductivity in the 'peroxidized' system (*p*H 8–10) which may be attributed to the lack of polymerization of the silicate ion in this system. The suggestion is therefore made that the study of the hydrolysis of the silicate ions is rendered less complex in the presence of hydrogen peroxide.

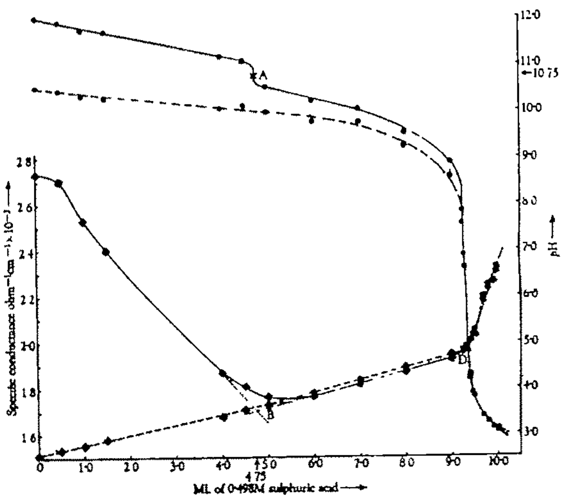

Fig. 1. Measurements of specific conductivity (◆) and *p*H (●) for the systems sodium silicate – hydrogen peroxide – water (dotted lines) and sodium silicate – water (full lines)

Detailed results of our investigation will be published elsewhere. We wish to acknowledge a research grant from Joseph Crosfield and Sons, Ltd., and the gift of pure unstabilized hydrogen peroxide from Laporte Chemicals, Ltd.

Volatile Organic Matter in Algal Culture Media and Sea Water

DURING an investigation of the extracellular products of marine algae, in which filtered culture media were concentrated by vacuum distillation, the distillates, which had an appreciable odour, were found to have a greater absorption of ultra-violet light than distilled water. The absorption of distillates increased by distilling at atmospheric pressure with ice cooling, a spray trap being incorporated in the apparatus. Examples of spectra from filtrates of uni-algal cultures of *Enteromorpha* sp., *Phaeocystis pouchetii* and *Phaeodactylum tricornutum*, bacteria-free *Ectocarpus confervoides* and membrane-filtered sea water are shown in Fig. 1. The overall shape of the absorption curves is somewhat affected by rate of boiling, degree of cooling, alkalinity of sample and freshness of the distillate. This suggests that more than one constituent may be present.

By redistilling distillates under various conditions it is possible to estimate that the recovery of volatile ultra-violet absorbent material is about 50 per cent when a distillate of 250 ml. is collected from a sample of 2·5 l. Measurements with CH_3COOH, C_2H_5COOH,

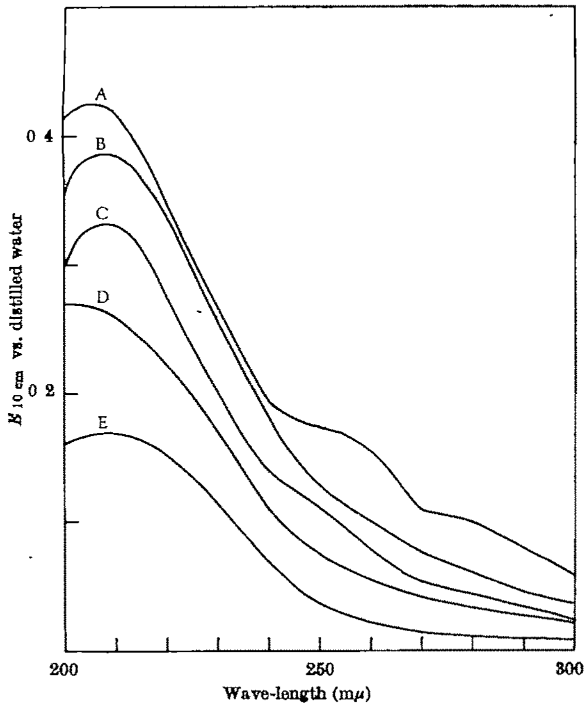

Fig. 1. *A*, *Ectocarpus* (× ½); *B*, *Phaeodactylum*; *C*, *Enteromorpha*; *D*, *Phaeocystis*; *E*, sea water

$CH_2OHCOOH$, H_3BO_3, $HCHO$, CH_3CHO, $(CH_3)_2CO$, $(CH_3)(C_2H_5)CO$, NH_3, CH_3NH_2, $(CH_3)_2NH$, $C_3H_7NH_2$ have shown that the absorptions found can only be accounted for if these substances are present (singly or as a mixture) at concentrations exceeding about 10 mgm./l. in the sample. Formic acid or trimethylamine at concentrations of about 1 mgm./l. could account for the ultra-violet absorption; but the former is unlikely to be volatile from sea water and the latter would necessitate larger carbon values than were actually found.

That the volatile material is at least partly organic is shown by carbon estimations carried out as follows. The distillates were boiled, after the addition of sodium hydroxide to retain carbon dioxide, and the vapours passed with a stream of oxygen through a simple 'empty tube' combustion train. The re-distillation with alkali causes the loss or retention in the flask of nearly 50 per cent of the ultra-violet absorptive material. This heavy loss suggests that in fact the carbon content of the volatile material may be a good deal higher than the figures in Table 1 indicate.

Table 1. CARBON AND SULPHUR DETERMINATIONS IN FILTERED CULTURE MEDIA AND IN SEA WATER

	Carbon (μgm./l.)	Sulphur (μgm./l.)

The characteristically 'weedy' odour of the distillates suggested the presence of organic sulphides since Haas[1] has shown that these substances are released from some marine algae. Micro-estimations of sulphur were carried out as follows. The distillates were passed through a small column packed with sulphur-free sugar charcoal, which had been found to remove odour and ultra-violet absorbent material. The absorbed material was volatilized at 600° C. in a stream of hydrogen and passed through a tube furnace at 1,000° C. to convert sulphur compounds to hydrogen sulphide[2]. This was then determined colorimetrically by the 'Lauth's violet' method of Polson and Strickland[3]. Sulphur contents of 1–4 μgm. sulphur/l. were found in samples of offshore sea water and higher values in cultures (see Table 1). Hydrogen sulphide could not be detected in the distillates (less than 0·1 μgm. sulphur/l. in the samples). If the sulphur were present as dimethyl sulphide the quantities found are quite insufficient to account for all the ultra-violet absorption. Further, the carbon : sulphur ratio is greater than in this compound. The nature of the other carbon compounds which must be present is as yet unknown.

These volatile materials were present in the media from bacteria-free cultures of *Ectocarpus* and appear to be released by the alga. Also, since they can be detected early in the growth of cultures of *Ectocarpus*, *Phaeocystis* and *Phaeodactylum* they are probably produced during healthy growth.

Fogg and Boalch[4] have already shown the presence of considerable quantities of extracellular nitrogenous matter in *Ectocarpus* cultures, and have suggested that it may have importance as a chelating agent. If the volatile sulphur is present as dimethyl sulphide or related compounds (which are known to form complexes with heavy metal salts[5]), the metal-binding properties of the extracellular products may be enhanced and may partly account for the marked resistance of *Ectocarpus* to compositions containing copper and mercury[6].

Some Phenolic Constituents of Cigarette Smoke

PHENOL and a number of substituted phenols have strong tumour-promoting properties[1], and similar activity has recently been demonstrated in a phenolic fraction of cigarette smoke (Salaman, M. H., and Roe, F. J. C., private communication). It seemed of interest, therefore, to record some results we have obtained in an examination of phenols from the smoke of a variety of British cigarettes.

The cigarettes were smoked mechanically (2 sec. puff of 25 c.c. every 15 sec.) and the smoke was condensed in traps at −60°. Volatile material was removed from the condensate by co-distillation with methanol, and the remaining tar, in methanol, was cooled to 0° to precipitate waxes. The filtered solution, in ether, was extracted successively with dilute aqueous acetic acid, sodium bicarbonate and sodium hydroxide, and the material recovered from the sodium hydroxide extract was methylated with diazomethane. Carboxylic acid esters present in the crude methylation product were hydrolysed with boiling ethanolic potassium hydroxide and the phenol ethers distilled. The compounds listed in Table 1 were obtained from a fraction b.p. 150–300° (1·1 gm. from smoke of 5,000 cigarettes) by gas-liquid chromatography[2]. They were identified by preparation of crystalline derivatives which were compared with authentic specimens and, where possible, by infra-red and ultra-violet absorption measurements. The cresyl ethers were eluted together from the chromatogram; the free cresols, however, were easily separated by counter-current distribution between benzene and a phosphate buffer as described by Golumbic[3]. The methoxyacetophenones obtained from the chromatogram were contaminated with unidentified material but this was removed by crystallization of the 2 : 4-dinitrophenylhydrazones.

The cigarette smoke must have contained the parent phenols of the ethers listed in Table 1 (veratrole, of course, could have arisen from either catechol or guaiacol). Some of the phenols have already been detected in cigarette smoke by spectroscopic and other means[2,4,5], and the isolation of phenol, *m*-cresol and guaiacol as their 3 : 5-dinitrobenzoates from smoke of Japanese cigarettes was reported[5] after the completion of the present work. The hydroxyacetophenones, however, have not previously been found in cigarette smoke. It is of interest, with regard to the promoting activity of the phenolic fraction of cigarette smoke (Salaman, M. H., and Roe, F. J. C., private communication), that phenol itself and the three cresols have all been shown to have tumour-promoting properties.

Results closely similar to the above were obtained by Mr. G. W. J. Matthews in this Laboratory by gas-liquid chromatography of phenol ethers derived from smoke of a brand of Argentinian cigarette said to contain fermented tobacco.

Table 1. GAS-LIQUID CHROMATOGRAPHIC SEPARATION OF PHENOL ETHERS DERIVED FROM CIGARETTE SMOKE

Peak No.	Compound	Estimated mgm. in smoke from 5,000 cigarettes	Crystalline derivative prepared
1	Anisole	40	2 : 4-dibromoanisole, m.p. 60°
2	*o*-Cresyl methyl ether	100	*o*-cresyl-3 . 5-dinitrobenzoate, m.p. 137°
	m-Cresyl methyl ether		*m*-cresyl-α-naphthylurethane, m.p. 126°
	p-Cresyl methyl ether		*p*-cresylbenzoate, m.p. 70°

4	Unidentified	120	
5	*m*-Methoxyacetophenone + unidentified	(10)*	2 : 4-dinitrophenylhydrazone, m.p. 189–190°
6	*p*-Methoxyacetophenone + unidentified	(5)*	2 : 4-dinitrophenylhydrazone, m.p. 229–230°

Column 6 ft. × 1 in., 20 per cent silicone grease *E* 301 on 80–100 mesh acid-washed 'Celite'; nitrogen flow-rate, 100 ml./min. Temperature was not measured, but was arranged so that anisole was eluted in about 10 min. Fractions were collected in traps at – 60° C.

* Estimated from weights of 2 : 4-dinitrophenylhydrazones.

Simple phenols have been found in cured tobacco leaf but they appear to be present in very small amounts[6]. The alkali-soluble fraction of an alcoholic extract of our cigarette tobacco afforded, after methylation, a significantly smaller amount of phenol ethers with boiling points below 300° C. than we obtained from the cigarette smoke, and it seems very likely that at least a proportion of the phenols in the smoke is produced by pyrolytic decomposition of other tobacco constituents.

We are indebted to Dr. J. W. Cook for his interest in this investigation.

BIOCHEMISTRY

Effect of Sulphydryl Group Reagents on Tryptophanase Activity

BOTH Gunsalus *et al.*[1] and Wada *et al.*[2] have reported that the presence of glutathione is advantageous during the assay of tryptophanase preparations. Wada *et al.* have also reported studies on the inhibition of tryptophanase by a number of SH-group reagents, and have suggested that the group is involved in the linkage between apoenzyme and substrate[3]. When we compare results which we have obtained at intervals since 1942, there is much agreement between us, but divergences, which may or may not be significant, do exist. Evans, Handley and Happold[4] reported a 12–20 per cent reduction of activity in washed cell preparation with sodium iodoacetate in a final concentration of $M/33$, and in later work with cell-free preparations activities were reduced by 20–25 per cent at concentrations of $5 \times 10^{-3} M$. At lower concentrations 5×10^{-5} and $10^{-6} M$ there has been no inactivation or even from time to time an apparent increase in the activity of the preparations. Further studies on inhibition were reported by Dawes and Happold[5]. Such preparations of tryptophanase are not necessarily free from other enzymes associated with pyridoxal phosphate-linked enzyme systems nor from the system which produced pyridoxal phosphate from pyridoxamine phosphate which Beechey and Happold described as a transaminase and which we now know contains a pyridoxamine phosphate oxidase similar to that found by Pogell in rabbit liver preparations; these divergences may be significant. During work in these laboratories on the purification of tryptophanase, the inhibition of activity by the SH-group alkylating reagent chloroacetophenone, and the reversal of SH-group inactivation, have been studied.

Table 1. Effect of Chloroacetophenone Concentration on Tryptophanase Activity

Chloroacetophenone concentration (*M*)	Tryptophanase activity	
	μgm. indole/5 min.	Percentage
0	25·5	100
$0·2 \times 10^{-6}$	25·5	100
$0·2 \times 10^{-5}$	24·3	95
$0·4 \times 10^{-5}$	14·3	56
$0·2 \times 10^{-4}$	6·9	27
$0·2 \times 10^{-3}$	0	0

The enzyme preparations used were obtained from *Escherichia coli*, and the tryptophanase activity was measured, as described by Beechey and Happold[6]. Reaction mixtures contained 0·5 ml. each of enzyme preparation (approximately 0·5 mgm.) protein; phosphate buffer (0·1 *M*, *p*H 7·8); potassium chloride solution (0·1 *M*); pyridoxal phosphate (100 μgm.); D,L-tryptophan ($1·96 \times 10^{-3}$ *M*, for L-form); and additions to 3·0 ml. Under these conditions at 37°, the rate of reaction was linear during the first 5 min., after which time 0·5 ml. of 10 per cent trichloracetic acid was used to stop the reaction. The indole produced was measured as previously described[6]. Pre-incubation with various reagents was carried out using reaction mixtures complete except for the addition of substrate.

Preliminary studies showed that chloroacetophenone at a final concentration of $0·2 \times 10^{-3}$ *M* required 20–30 min. pre-incubation for maximum inhibition. Using a 30-min. pre-incubation time, the effect of concentration of chloroacetophenone is shown in Table 1.

The effect of glutathione, at various concentrations, on the inhibition of tryptophanase activity by chloroacetophenone is shown in Table 2.

Table 2. Effect of Glutathione on Chloroacetophenone Inhibition of Tryptophanase

Glutathione concentration (*M*)	Tryptophanase activity (μgm. indole/5 min.), at various chloroacetophenone concentrations (*M*)				
	$0·2 \times 10^{-3}$	$0·4 \times 10^{-4}$	$0·2 \times 10^{-4}$	$0·4 \times 10^{-5}$	0
0	0·4	9·2	15·5	26·8	30·0
$0·2 \times 10^{-3}$	4·5	25·3	26·1	32·5	33·3
$0·2 \times 10^{-2}$	24·0	25·0	29·6	33·3	33·0

Glutathione was pre-incubated with enzyme for 60 min., after which chloroacetophenone was added and the mixture incubated for a further 30 min.

It can be seen that not only does glutathione protect tryptophanase from inhibition by chloroacetophenone, but also that it sometimes increases the activity of the preparation where no chloroacetophenone is present.

Further experiments showed that the extent of the increase in tryptophanase activity due to glutathione depended on the source and storage history of the preparation used. Maximum activation was found to occur at a glutathione concentration of $0·2 \times 10^{-2}$ *M*. When glutathione was replaced by cysteine in these experiments, initial results suggested progressive inhibition rather than activation. It was observed, however, that the yellow colour of reaction mixtures, due to pyridoxal phosphate, rapidly disappeared after the addition of cysteine. When pre-incubation of enzyme with cysteine was followed by the addition of co-factor only 5 min. before the addition of substrate, an increase in tryptophanase activity occurred. Here again, however, the extent of activation was variable, depending on the history of the enzyme preparation. Representative results are given in Table 3.

Table 3. Effect of Pre-incubation Time on the Activation of Tryptophanase by Cysteine

Pre-incubation time (min.)	Tryptophanase activity	
	μgm. indole/5 min.	Percentage of control
99·5	17·5	400
37·5	7·9	184
20·5	6·4	149
6·5	6·1	142
Control (no cysteine)	4·3	100

Pyridoxal phosphate was added at the end of pre-incubation, 5 min. before addition of substrate. Cysteine concentration was $0·2 \times 10^{-2}$ *M*.

It thus appears that cysteine enhances tryptophanase activity, presumably by reduction of oxidized SH-groups, but that this activation is masked by the removal of coenzyme, possibly by Schiff base formation. As the removal of coenzyme leads to the irreversible destruction of tryptophanase activity in the absence of metal ions, it appears that glutathione rather than cysteine should be used to protect the integrity of SH-groups during the purification of tryptophanase.

When sodium *p*-chloro mercuric-benzoate was used as an SH-group reagent inhibition showed itself at concentrations of 8×10^{-7} *M* and was almost absolute at 8×10^{-4} *M*. The tryptophanase activity was more than restored with 8×10^{-4} *M* glutathione.

Further work, which is continuing in these laboratories, indicates that cysteine protects tryptophanase from inhibition by chloroacetophenone. The reducing agent ascorbic acid has been found to inhibit tryptophanase activity under all conditions, but the reason for this remains obscure.

We wish to thank Miss Barbara Clough for technical assistance.

Antigenicity of Œstrone–Protein Conjugates

The purpose of the present study was to determine whether steroids, when conjugated by stable covalent bonds to proteins, could act as haptenic groups in inducing steroid-specific antibodies. A detailed account of the method used for synthesizing œstrone–protein conjugates has been published elsewhere[1]. In brief, œstrone was converted to œstrone-17-*iso*cyanate and the latter was allowed to react with human and bovine serum albumin to yield the corresponding œstrone-17-carbamido-protein conjugates.

Rabbits were immunized with the œstrone–human serum albumin conjugate and the presence of precipitating antibodies in the sera was shown by the ring test. Two types of antibody were detected. One type was precipitated with œstrone–bovine serum albumin conjugate but not with bovine serum albumin and the reaction was inhibited by œstrone-17-carbamido-glycine. The other type was precipitated with human serum albumin but this reaction could not be inhibited with the glycine derivative of œstrone.

These results demonstrate that specific antibodies were produced to (1) the œstrone residue and (2) the protein carrier. The production of a third type of antibody, directed to the carbamido linkage itself, was ruled out since no reaction was obtained with butyl–carbamido–bovine serum albumin conjugate.

These conclusions were confirmed by three other methods.

(1) Dale–Schultz[2]: Guinea pigs were passively sensitized with rabbit antiserum produced to the œstrone-human serum albumin conjugate and their uteri were mounted in a Dale–Schultz apparatus. Addition to the bath of œstrone–bovine serum albumin conjugate and of human serum albumin resulted in the usual uterine contraction (Fig. 1*a*). However, addition of bovine serum albumin was without effect (Fig. 1*b*). Prior incubation of the uteri with the glycine derivative of œstrone completely inhibited the contraction due to the conjugate but not to human serum albumin (Fig. 1*c*).

(2) B.D.B.–Hæmagglutination: The œstrone–bovine serum albumin conjugate and human serum albumin were coupled to rabbit erythrocytes via *bis*-diazotized-benzidine[3,4]. The sensitized erythrocytes were added to serial dilutions of rabbit antiserum to œstrone–human serum albumin conjugate with and without various test inhibitors. Œstrone–bovine serum albumin conjugate as well as the glycine derivative of œstrone strongly inhibited hæmagglutination of erythrocytes sensitized with the conjugate while testosterone-17-glucoside and 17-hydroxycorticosterone-21-sodium succinate exhibited lower inhibiting activity. On the other hand, none of the test inhibitors mentioned had any effect on hæmagglutination of the erythrocytes sensitized with human serum albumin.

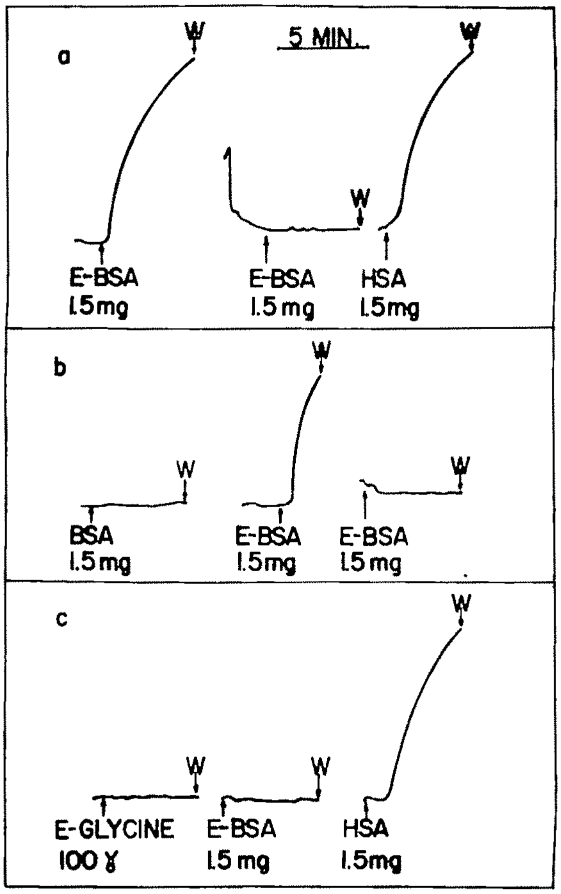

Fig. 1. *W*, Washing with Tyrode solution; *E-BSA*, œstrone–bovine serum albumin conjugate; *HSA*, human serum albumin; *BSA*, bovine serum albumin; *E-GLYCINE*, œstrone-17-carbamido–glycine

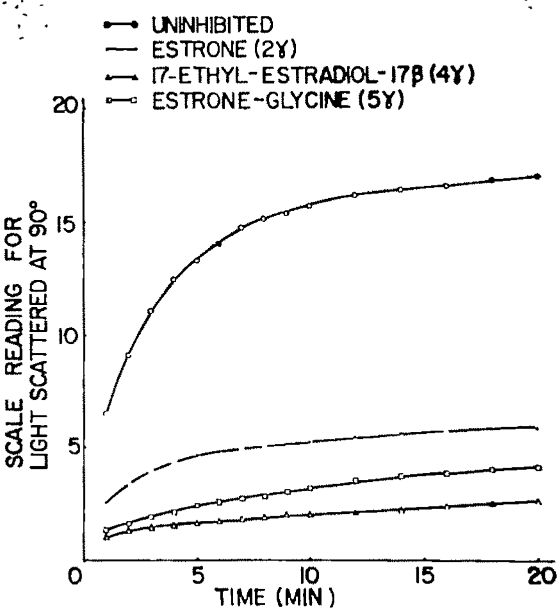

Fig. 2

(3) Turbidimetry: The course of the reaction between the conjugate of œstrone with bovine serum albumin and the rabbit antiserum to œstrone–human serum albumin conjugate was followed turbidimetrically by measuring light scattered at 90° with a Beckman *DU* spectrophotometer (cf. ref. 5). The curves obtained for the reaction at optimal antigen–antibody concentrations in the absence and in the presence of œstrone, the glycine derivative of œstrone and 17-ethynyl-œstradiol-17β are shown in Fig. 2. It can be seen that the steroids caused a marked reduction in turbidity; the percentage reduction in turbidity, due to these and other structurally related compounds, is given in Table 1.

The results presented demonstrate that the œstrone residue acts as a hapten when coupled to protein, and that the antibody site complementary to the œstrone residue is capable of accommodating not only œstrone but other structurally related molecules as well. These findings confirm in essence the conclusions of Beiser, Erlanger, Agate and Lieberman[6],

Table 1

Inhibitor	Amount added (γ)	Inhibition (per cent)*
Œstrone	2	66

Lack of Correlation between Synthesis of Nucleic Acids and Proteins in Denervated Muscle

After direct electrical stimulation of a muscle, non-collagen protein decreases and is later re-synthesized[1]. The rate of resynthesis is considerable, 1·9 mgm. of non-collagen protein/gm. of muscle tissue being resynthesized during 1 hr. The course of this accentuation of proteosynthesis was followed in the normal and denervated muscle. Fig. 1 shows that the decrease of proteins after stimulation of the muscle is the same in normal and denervated muscle and is accompanied by a decrease of ribonucleic acid, amounting to 15 per cent in the normal and 50 per cent in the denervated muscle. Such a decrease of ribonucleic acid and also an increase in proteolysis has been described after stimulation of nerve and brain tissue[2].

M. tib. anticus in rats was directly stimulated at a frequency of 300/min. for 6 min. Immediately, 2, 4 and 8 hr. after stimulation the muscles of the stimulated and control side were perfused with Tyrode solution. Following perfusion, both muscles were excised and the absolute amount of non-collagen proteins was determined (biuret method). The amount of ribonucleic acid was determined (Schneider's method) in another series of animals. The results are expressed in Fig. 1 as differences between the stimulated and control side. The first point of the curve corresponds to the difference between the muscle of the right and left side in control animals. Zero on the abscissæ represents the values immediately after stimulation. Proteins are expressed as μgm. non-collagen nitrogen/muscle. Ribonucleic acid values are expressed as μgm. ribonucleic acid phosphorus/100 mgm. protein nitrogen.

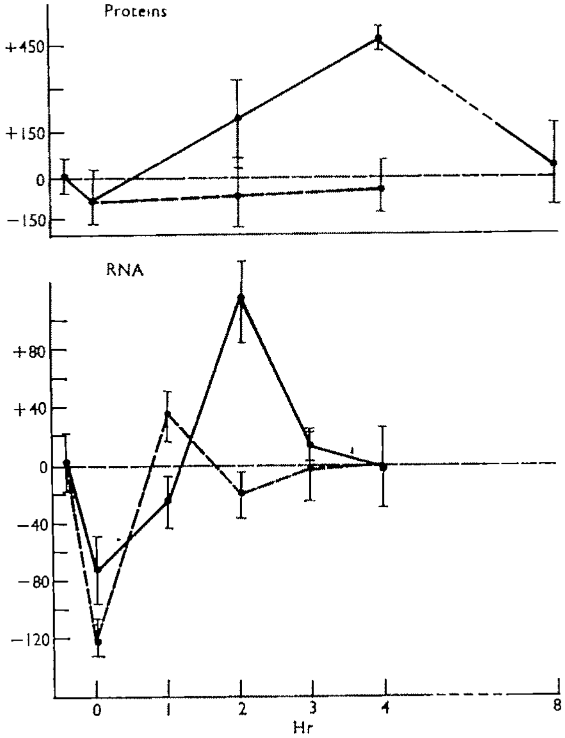

Fig. 1. Changes of non-collagen proteins and ribonucleic acid after stimulation of the normal (full line) and denervated (interrupted line) muscle

Fig. 1 shows that resynthesis of ribonucleic acid and proteins occurs after their breakdown in the normal muscle. However, the content of proteins and nucleic acids not only reaches the initial values but also their synthesis continues, the content of the proteins being 5 per cent above the initial values 4 hr. after stimulation, the content of ribonucleic acid being 22 per cent above the initial values 2 hr. after stimulation.

During the further course of the recovery phase following stimulation of the muscle, the content of proteins and ribonucleic acid returns to initial levels. The 'overshoot' reactions are apparently of general biological significance, since they have also been found during the process of resynthesis of glycogen[3] and during the restitution of the composition of ions in the muscle following stimulation.

These experiments also show that the recovery of ribonucleic acid following stimulation of the muscle precedes the resynthesis of proteins. Such a time correlation between the synthesis of ribonucleic acid and proteins has also been found in, for example, regenerating liver[5] and after the administration of growth-hormone[6]. After stimulation of the denervated muscle, resynthesis of ribonucleic acid, but not of the proteins, occurs.

There is therefore a certain lack of correlation between the resynthesis of proteins and ribonucleic acid in denervated muscle. The same lack of correlation was also observed during re-alimentation following starvation, which lowers both proteins and ribonucleic acid. Table 1 shows that the ribonucleic acid content is increased by 36·5 per cent within 12 hr. after re-alimentation and that resynthesis continues so that 60 hr. later ribonucleic acid increases by 80 per cent. Compared with ribonucleic acid, proteosynthesis was found to be delayed.

Table 1. CHANGES IN THE NET AMOUNT OF NON-COLLAGEN PROTEINS AND RIBONUCLEIC ACID IN M. TIB. ANTICUS OF RATS FOLLOWING A HUNGER PERIOD OF 10 DAYS AND AFTER RE-ALIMENTATION

Type of experiment	Proteins (µgm. non-collagen protein N/muscle)		Ribonucleic acid (µgm. ribonucleic acid P/muscle)	
	Right side	Left side	Right side	Left side
Control animals (6 rats)	9·2±0·4	9·0 ±0·5	41·6±0·6	41·0±0·4
	$P > 0·1$		$P > 0·1$	
	Before re-alimentation	After re-alimentation	Before re-alimentation	After re-alimentation
10 days hunger and 12 hr. re-alimentation (9 rats)	5·8±0·3	5·9 ±0·2	22·1±1·9	30·2±1·5
	$P > 0·1$		$P < 0·01$	
10 days hunger and 72 hr. re-alimentation (8 rats)	6·6±0·3	8·0 ± 0·2	20·6±0·7	37·0±1·4
	$P < 0·02$		$P < 0·001$	
10 days hunger and 72 hr. re-alimentation after denervation (16 rats)	6·7±0·2	6·3 ±0·3	22·8±1·4	29·4±1·0
	$P > 0·1$		$P > 0·001$	

In all animals the muscle of one side was removed at the end of the hunger period; the muscle of the contra-lateral extremity was removed 12 and 72 hr. after re-alimentation. Denervation was performed immediately before re-alimentation.

A significant increase in non-collagen protein was found only 72 hr. after re-alimentation. If the muscle is denervated immediately before re-alimentation, there is only an increase of ribonucleic acid but no increase of non-collagen protein after 72 hr. Similar results are thus obtained in both types of experiments.

The disturbance of proteosynthesis in denervated muscle could be due to the dissociation of the synthesis of nucleic acids and proteins.

Some Interrelated Aspects of Proline and Hydroxyproline Metabolism

PROLINE is known to be the sole source of hydroxyproline residues in collagen[1] and is converted to hydroxyproline only after its incorporation into a polypeptide[2,3]. If proline labelled with carbon-14 is employed as a specific precursor of hydroxyproline residues of collagen, the isotope concentration in urinary excretion products derived from such residues should reflect the rate of collagen catabolism. Pyrrole-2-carboxylic acid, an important product of hydroxyproline catabolism[4], as well as 'free' hydroxyproline and 'bound' hydroxyproline, was studied in these experiments. The present communication deals with the metabolic interrelationships between these urinary excretion products. For purposes of comparison the metabolic behaviour of proline and hydroxyproline residues of skin collagen is also considered.

The pertinent results are shown in Table 1. Some points are noteworthy: (1) The rate of turn-over of 'free' hydroxyproline is identical with that of pyrrole-2-carboxylic acid, thus extending the findings of Radhakrishnan and Meister[4]. (2) The rate showing the decrease of carbon-14 activity with time indicates that in the pools of 'free' hydroxyproline and pyrrole-2-carboxylic acid two metabolically distinct components are present which have a rapid and a slow turn-over rate, respectively. (3) During the days immediately following the injection of proline-U-^{14}C, the carbon-14-activity of the 'total' hydroxyproline fraction in urine is considerably lower than that of the 'free' hydroxyproline fraction. Thereafter the turn-over rate of the 'total' hydroxyproline fraction resembles that of the 'free' hydroxyproline and pyrrole-2-carboxylic acid fractions characterized by a slow turn-over rate. (4) The hydroxyproline residues in skin collagen are labelled rapidly. One day after injection of proline-U-^{14}C about 70 per cent of all proline residues destined to be hydroxylated have been converted to hydroxyproline. These findings are in agreement with those of Stetten and Schoenheimer[1] and are similar to those of Sinex and Van Slyke[5], who studied the conversion of lysine to hydroxylysine in collagen.

The existence of two metabolically distinct components in the 'free' hydroxyproline and pyrrole-2-carboxylic acid pools may be explained in at least two ways: (1) Two different metabolic pools of collagen may exist, one representing a labile fraction which is catabolized readily to pyrrole-2-carboxylic acid or 'free' hydroxyproline and the other constituting the source of 'bound' hydroxyproline. It is conceivable that the component having a rapid turn-over represents a transitory state preceding the stabile state of the collagen molecule. On the basis of the results presented, it might be speculated that proline residues are hydroxylated most rapidly when the polypeptide is in the labile, transitory state. (2) Because of its fibrous structure, collagen may not behave in accordance with the classical concepts of metabolic turn-over. Instead of the generally accepted mechanism for *de novo* synthesis of a macromolecule, the formation of new peptide bonds might be limited to the terminal sequences of amino-acid residues of the collagen fibres. This postulate is compatible with the experimentally observed non-uniform labelling of collagen by glycine-2-^{14}C [6] and phenylalanine-3-^{14}C [7]. It might, therefore, be postulated that the probability of metabolic activation of an amino-acid residue of collagen is dependent upon the distance at which the residue is located with respect to the metabolically active end of the fibre.

Table 1. SPECIFIC ACTIVITIES* OF URINARY EXCRETION PRODUCTS OF HYDROXYPROLINE RESIDUES AS WELL AS OF PROLINE AND HYDROXYPROLINE ISOLATED FROM SKIN COLLAGEN

	Days after injection of proline-U-^{14}C			
	1	2	3	6
Pyrrole-2-carboxylic acid	126	32	7·5	2·8
'Free' hydroxyproline	110	25	6·8	3·0
'Total' hydroxyproline	6·8	4·7	3·7	2·0
'Bound' hydroxyproline†		2·8	3·2	1·8
Proline of skin collagen	39		34·5	24·5
Hydroxyproline of skin collagen	22		24	21
Ratio of proline to hydroxyproline	0·56		0·7	0·88

Each of eight rats weighing 130 ± 4 gm. was injected with approximately 6·2 µc. of proline-U-^{14}C (specific activity, 7 µc./µM). Urine was then collected over several consecutive 24-hr. periods. The method devised for the isolation and determination of the urinary metabolites studied will be described in detail. Purification of skin collagen was carried out according to the procedures of Fitch (ref. 8).

* The specific activities are given as c.p.m./µM for 1 µc. of proline injected per 100 gm. animal weight.

† The specific activities of 'bound' hydroxyproline were computed from the values of 'total' and 'free' hydroxyproline using average values for the ratio of 'free' to 'total' hydroxyproline concentration (that is, approximately 1:13 in the urine of normally fed rats).

The results of these and other work on the metabolic behaviour of collagen will be published in detail elsewhere.

This investigation has been supported in part by a contract from the U.S. Atomic Energy Commission (*AT*-(30–1)-1286) and a research grant from the U.S. Public Health Service (*C*-4687), the Cancer Institute, National Institutes of Health.

Copper(II) Complexes of Histamine and 3-Methyl Histamine

In previous communications from this laboratory[1–3] evidence has been presented that acid dissociations occur from the 1 : 1 cupric complexes of histidine and histamine. In the presence of equimolar cupric chloride, one equivalent of alkali additional to that needed by either of the ligands alone is required to titrate all the acid produced. When the ligand/copper(II) ratio is 2 : 1 the amount of alkali required is the same as in the absence of the metal. From these facts it was concluded[2] that a co-ordinated water molecule and not the hydrogen attached to the unco-ordinated imidazole nitrogen was the source of the acid ionization from the 1 : 1 complexes. As a further test of this idea, we have investigated the copper(II) complexes of 3-methyl histamine.

Titration curves of 3-methyl histamine dihydrochloride in the absence and presence of cupric chloride are shown in Fig. 1. It can be seen that an acid ionization occurs from the 1 : 1 and not the 2 : 1 complex. Thus histamine and its 3-methyl derivative are similar in their co-ordinating properties with copper(II), and the interactions which occur may be represented thus:

$$\mathrm{Cu}^{2+} + L \underset{}{\overset{K_1}{\rightleftharpoons}} \mathrm{Cu}L^{2+} \qquad (1)$$

$$\mathrm{Cu}L^{2+} \overset{K_c}{\rightleftharpoons} \mathrm{Cu}L^{+} + \mathrm{H}^{+} \qquad (2)$$

$$\mathrm{Cu}L^{2+} + L \overset{K_2}{\rightleftharpoons} \mathrm{Cu}L_2{}^{2+} \qquad (3)$$

where

$$K_1 = \frac{[\mathrm{Cu}L^{2+}]}{[\mathrm{Cu}^{2+}][L]},\ K_c = \frac{[\mathrm{Cu}L^{+}][\mathrm{H}^{+}]}{[\mathrm{Cu}L^{2+}]},\ K_2 = \frac{[\mathrm{Cu}L_2{}^{2+}]}{[\mathrm{Cu}L^{2+}][L]}$$

The constants were calculated by the methods previously described[3] and the numerical values obtained did not vary significantly with pH (at 25° C. $pK_{a1} = 5{\cdot}80$, $pK_{a2} = 9{\cdot}90$, $\log K_1 = 9{\cdot}58$, $\log K_2 = 6{\cdot}56$, $pK_c = 7{\cdot}10$, where K_{a1} and K_{a2} are the acid dissociation constants of the ligand). These values are not very different from those reported for histamine[3].

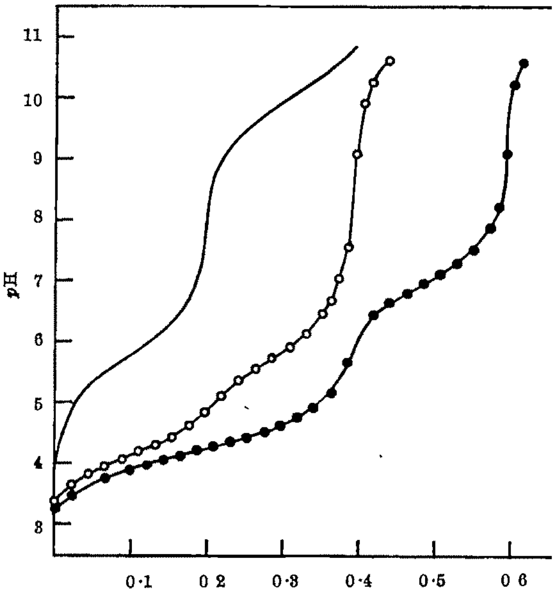

Fig. 1. Titration curves of 3-methyl histamine dihydrochlorid (0·2 mM in 20 ml.) with sodium hydroxide (0·11 N): ——, n additions; —○—○—○—, plus 0·1 mM cupric chloride —●—●—●—●—, plus 0·2 mM cupric chloride

The hydrogen attached to the unco-ordinat imidazole nitrogen cannot be the source of the ac dissociation from the histamine complex, since t hydrogen is not present in 3-methyl histamine and is most unlikely that the two ligands differ in t nature of the complexes they form. The eviden therefore, favours the previous suggestion that t acid dissociation (equation 2) occurs from a wat molecule co-ordinated to the 1 : 1 complex, CuL or the equivalent process, the uptake by this compl of a hydroxyl ion.

We are indebted to Dr. R. W. Schayer, Mer Institute of Therapeutic Research, for kindly suppl ing the 3-methyl histamine dihydrochloride used this investigation.

ANIMAL PHYSIOLOGY

Renal Affection resulting from Blood Trauma in Extracorporeal Circuits

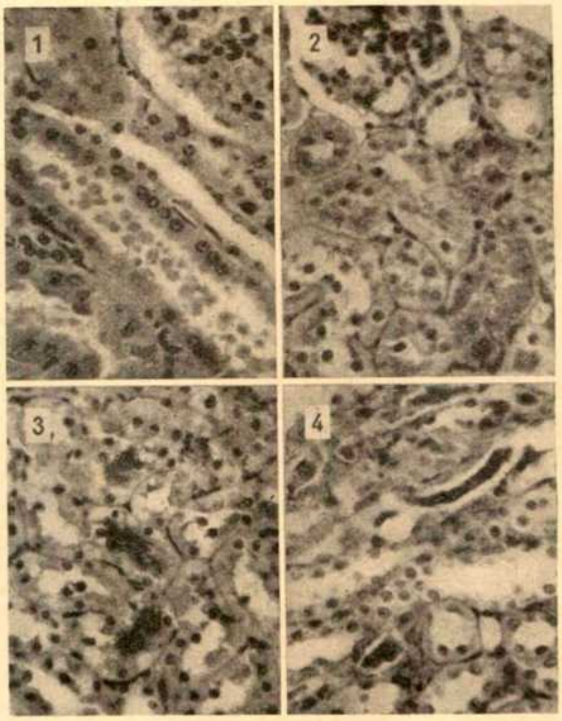
Previously, we have presented evidence that as result of the corpuscular blood trauma inherent extracorporeal circulatory systems including t heart–lung machines, adenosine triphosphate a 5-hydroxytryptamine (serotonin) are released in plasma, the former being derived mainly from t hæmolysed red cells and the latter from the disi tegrated platelets. Concurrently, the urinary exc tion of 5-hydroxytryptamine was increased, wh rather unexpectedly, there was a reduction in t excretion of 5-hydroxyindoleacetic acid, the main excretory product of hydroxytryptamine[1]. Since intravasal hæmolysis caused in any way may evoke an acute tubular ('lower nephron') nephrosis[2,3] and since, on the other hand, 5-hydroxyindoleacetic acid has been reported to be excreted also by active tubular secretion[4], we have studied the renal changes in a part of the animals, in which the above blood and urinary changes were found.

The animal material studied comprised four rabbits and three dogs. The experimental procedure was described in our previous report[1]. In brief, the animals were pretreated with pethidine hydrochloride, anæsthetized with pentobarbitone sodium and heparinized, following which an arteriovenous (femoral artery-superficial jugular vein) shunt, consisting of a specially prepared polythene tube, was created. In the period of this extracorporeal circulation, maintained for 90 min., the blood and urinary changes were observed. In general, the animals were killed at the termination of extracorporeal circulation, except one dog, in which the experiment was repeated one week later. At autopsy, both the kidneys were excised and fixed in neutral 10 per cent formalin. The embedded material was serially sectioned and stained with hæmalum–eosin and hæmalum–periodic acid Schiff-orange *G*. Frozen sections were stained with a mixture of sudan III and sudan IV for fats and with benzidine for hæmoglobin.

Pathological renal changes were found in both rabbits and dogs. In rabbits the changes generally consisted of some glomerular congestion associated with a leakage of eosinophilic, periodic acid–Schiff-positive material into the glomerular space (Fig. 1). The proximal convoluted tubuli showed a more or less intense intracellular deposition of orange *G*-positive material (Fig. 2), which also gave a positive benzidine-reaction. In addition, eosinophilic, orange *G*-positive material, in the form of granular bodies, droplets (Fig. 1) or plugs (Fig. 3), were seen especially in the lumina of the proximal convoluted tubuli. In the lower portions of tubuli there were eosinophilic, intensely periodic acid–Schiff-positive casts (Fig. 4). No definite destructive changes were observed in the tubular epithelium ; but in the intertubular vascular bed of the medulla there was a patchy type of congestion with occasional thrombosis. Fatty changes were consistently lacking. In dogs, changes of the same general type were encountered ; but they were less pronounced and the patchy vascular changes were absent. In the three rabbits and three dogs studied for comparison none of the changes described were seen.

Accordingly, the pathological renal changes observed largely correspond to those typical of the so-called 'lower nephron nephrosis'[2,3]. The lack of any definite destructive tubular changes may well be related to the short reaction time in the present experiments. The observation that the renal changes were less pronounced in dogs agrees with our finding, previously reported[1], that the corpuscular and humoral indices of blood trauma also were less pronounced in dogs. This also demonstrates that the renal changes under consideration are pathogenetically related to the blood trauma observed in our animals[1].

The glomerular and tubular structures were not affected throughout. On the other hand, the dog, in which the experiment was repeated one week later, did not show any pathological renal changes suggestive of irreversibility. Thus, the renal changes described can scarcely be regarded as being serious, especially *quo ad vitam*. Yet the present finding may be of significance at least in two respects. First, the unexpected reduction in the excretion of 5-hydroxyindoleacetic acid, as observed in our animals[1], may be related to some injury to the proximal convoluted tubuli, to which monoamine oxidase, essential for the conversion of 5-hydroxytryptamine into 5-hydroxyindoleacetic acid, is localized in the kidney[5] and in which the active secretion of 5-hydroxyindoleacetic acid presumably takes place[4]. In this respect, however, definite conclusions are not warranted, because the plasma-levels of 5-hydroxyindoleacetic acid were not observed in our animals and because detailed information on the mode of excretion of 5-hydroxytryptamine is not available for the present. Secondly, as pointed out previously[1], the corpuscular blood trauma in the present experiments was of the same general degree as that in the current heart–lung machines. A comparable degree of renal damage may therefore occur following the use of the current heart–lung machines for open cardiac surgery. Such renal damage may even be aggravated, should severe hypotension, as has been reported[6], ensue as a post-perfusion complication. It may be recalled that Daly and associates[7] found more severe renal changes, with occasional tubular necroses, in dogs perfused for about 3 hr. by means of a pump-oxygenator. They further found congestion, hæmorrhages and necrobiotic changes in other vital organs and were inclined to ascribe these changes as well as the allied signs of peripheral circulatory shock to 'vasotonins' appearing in the blood during perfusion. Our findings, previously discussed[1], suggest that adenosine triphosphate and 5-hydroxytryptamine may be the 'vasotonins' involved.



Figs. 1–4

Finally, Brull and Louis-Bar[8] have recently established the toxicity of artificially circulated, heparinized blood to the kidney and speculated that

5-hydroxytryptamine released from disintegrated platelets might be the causative agent. In their experience, furthermore, this toxic action could not be prevented by siliconizing the foreign channels.

The present studies have been supported by the Sigrid Jusélius Foundation and Medica, Ltd., Helsinki, and by the Upjohn Company, Kalamazoo, Mich.

Loss of Heat by Evaporation in Young Lambs

Animals exposed to temperatures approaching or exceeding that of the body can lose little or no heat by radiation, convection and conduction; they must rely partly or wholly on evaporative cooling from the skin or respiratory tract to maintain homeothermy.

Although sheep have been shown to have a high heat tolerance[1,2], no direct measurements of loss of water from the skin and from the respiratory tract have been reported for this animal. Such measurements have now been made in young lambs subjected to a wide range of environmental temperatures, and the relative importance of the two routes of evaporative heat loss has been assessed.

Four Merino lambs were examined during the first fifteen days of life; they were fasted for 4–12 hr. before each experiment, which lasted 1–1½ hr. The experiments were made in a closed-circuit respiration apparatus (indirect calorimeter) previously outlined[3], but here modified so that respiratory and cutaneous water losses could be determined separately. The lamb, in the chamber of the apparatus, respired into an air-tight polythene mask which covered the head and through which air was circulated. Oxygen was metered into the mask from a spirometer, and expired water vapour and carbon dioxide were determined by weighing. Cutaneous water-loss from the body and limbs was measured by weighing the water absorbed from the air circulating within the chamber. Water vapour pressures at the mask outlet and in the chamber were usually maintained within 3 mm. mercury of each other; they ranged from about 3 mm. mercury at 8° C. to 20 mm. mercury at 45° C. Turbulent air flow over the lamb was at the rate of about 30 cm./sec. Measurement of loss of water, etc., was usually not begun until ¾–1 hr. after the lamb had first been subjected to the experimental conditions.

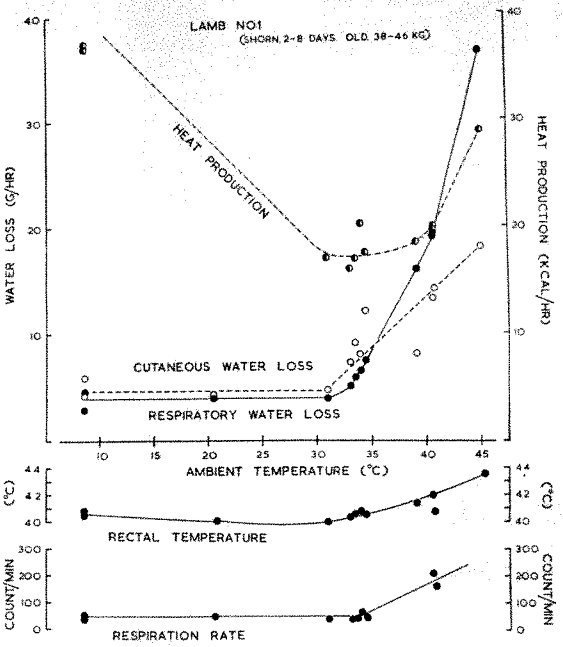

Fig. 1. Heat production, loss of water by evaporation, rectal temperature and respiration-rates in a shorn lamb at various ambient temperatures

The results from lamb No. 1 on which most observations were made are shown in Fig. 1. This lamb had been shorn closely to eliminate errors due to release or absorption of water by the fleece during the experiments. At ambient temperatures below 30° C., losses of water from the skin and from the respiratory tract were relatively constant, the former slightly exceeding the latter. Above 30° C., loss of water from both sources increased with increasing temperature, the rate of increase of the respiratory loss being the greater. Heat production and rectal temperature were minimal at 30° C.; respiration-rate was constant below 30° C. and increased above 30° C. Similar qualitative results were obtained in three other lambs which were not shorn (Fig. 2).

The break in the curve relating ambient temperature to cutaneous water loss suggests that an active

* Not determined.
† Water vapour pressure was gradually increased from 15 to 55 mm. mercury during the experiment.

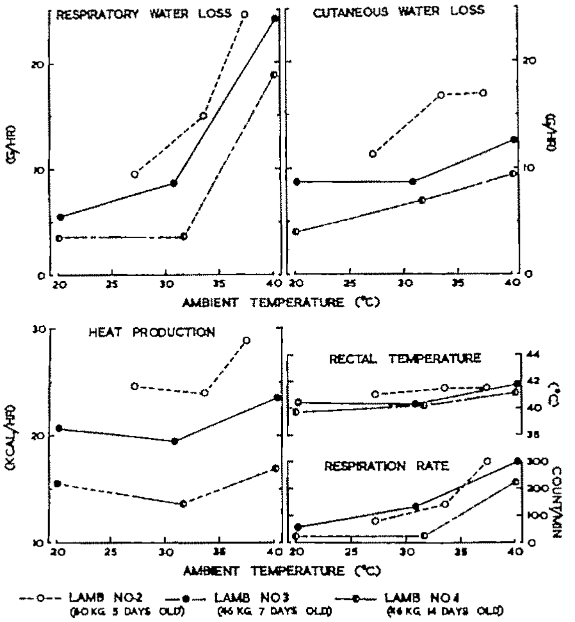

Fig. 2. Heat production, loss of water by evaporation, rectal temperature and respiration-rates in three unshorn lambs at various ambient temperatures

process had come into play above 30° C.; that is, sweating occurred.

The functional reserve of each channel of evaporative cooling was examined in two lambs at 40–41° C. by raising the humidity close to saturation in one channel, to reduce or virtually prevent evaporation, and measuring water loss from the other (Table 1).

In lamb No. 1 when loss of heat by evaporation from the skin was blocked, the loss by respiration was increased to compensate and it was able to prevent a severe rise in rectal temperature. On the other hand, when loss by respiration was much reduced, cutaneous loss was not capable of any marked response and rectal temperature rose rapidly. Although lamb No. 5 was unable to keep its rectal temperature down even when neither channel was blocked, its responses were similar to those of lamb No. 1.

These findings show that, in a hot environment, lambs lose heat by both panting and sweating, and that in the region of minimal heat production the contribution of each is about equal. However, at higher ambient temperatures, the contribution of panting becomes by far the greater, and there is a great functional reserve of evaporative cooling by this route. Sweating appears to approach its limit at that ambient temperature where heat losses by radiation, convection and conduction cease (Table 1).

Published data on adult sheep suggest that they, too, sweat[1,4,5]; but there is insufficient evidence to indicate whether the adult shows the same quantitative relation between sweating and panting as the young. However, results with lambs suggest that in the sheep the relative importance of sweating and panting differs from that in the few other species for which data are available. In the dog[6], sweating is of no consequence, while in the camel[7] and man it is virtually the sole means of evaporative cooling. Cattle, too, appear to rely mainly on sweating[8], but loss of water by respiration shows some increase in heat stress. In sheep, however, panting is apparently the more important mechanism of heat elimination, but sweating can contribute substantially to evaporative cooling.

Effect of β-Hydroxybutyrate Injections on the Pancreatic Activity of Guinea Pigs and Rats

A PRODUCT of the intermediary metabolism of fats, namely, β-hydroxybutyric acid, appears in excess during disturbed metabolic processes, especially in diabetic organisms. The accumulation of this intermediary product causes different pathological conditions (acidosis, etc.) in the animal. M. C. Nath and H. D. Brahmachari[1] and H. D. Brahmachari and Mahendra Kumar[2] conclude that chronic administration of β-hydroxybutyrate to guinea pigs and rabbits causes, after a transitory hypoglycæmia, a permanent hyperglycæmia and a lowered glucose tolerance, hypo-insulinism due to atrophy through over-stimulation of the *B*-cells of the pancreas.

Similar observations have been made in our laboratory[3], but after chronic administration of adrenocorticotrophic hormone. We concluded that the parenteral administration of β-hydroxybutyrate produces a mobilization of the adrenocorticotrophin from the hypophysis and, as a consequence, the symptoms observed by Brahmachari *et al.*[2] may be secondary processes due to excess production of corticosteroids as a consequence of the mobilization of adrenocorticotrophic hormone.

We have therefore extended the investigation. Experiments have been carried out on guinea pigs and on white rats of both sexes, divided into four experimental lots, each composed of 5 animals: (1) Normal rats and guinea pigs; (2) hypophysectomized rats; (3) normal rats and guinea pigs treated with β-hydroxybutyrate, 50–100 mgm. per animal; (4) hypophysectomized rats treated with the same dose of β-hydroxybutyrate.

The following determinations were made on each animal: (*a*) extent of glycæmia (photocolorimetrical method, Somogyi–Nelson[4,5]); (*b*) quantitative estimation of plasma-insulin (Vallance-Owen *et al.*[6]); (*c*) estimation of adrenocorticotrophic hormone in blood plasma (Sayers *et al.*[7], modified by us[8]).

The results given in Table 1 demonstrate clearly that during the administration of β-hydroxybutyrate (sodium salt) the glycæmia, after a temporary lowering, rises to 210 mgm. per cent. At the same time the quantity of plasma insulin—after a considerable

Table 1. EFFECT OF THE CHRONIC TREATMENT WITH SODIUM β-HYDROXYBUTYRATE ON NORMAL ANIMALS

No.	Days of injections	Glycæmia (mgm. per cent)	Insulin in plasma (microunits/ml.)	Adrenocorticotrophic hormone in plasma (milliunits/100 ml.)
1	0 (control)	98	92 ± 6	0·5 ± 0·1
2	7	69	310 ± 18	8·5 ± 3·1
3	14	71	360 ± 11	2·1 ± 2 3
4	28	110	135 ± 8	3·3 ± 1·1
5	35	180	60 ± 18	9·3 ± 3 1
6	42	210	80 ± 11	5·8 ± 5·1

increase—decreases to less than the normal values, whereas the level of adrenocorticotrophic hormone from the blood rises to about 10 times that of the initial values, that is to say, the normal values.

We observed in rats treated for 14, 28 and 42 days with this product a destruction of pancreatic *B*-cells, a destruction similar to that observed in rats treated chronically with adrenocorticotrophic hormone, as described by us[8].

These results confirm Brahmachari's observations concerning the diabetogenic effect of the β-hydroxybutyrate.

In order to analyse the mechanism of the action of this substance, we subjected some rats to hypophysectomy, afterwards treating them chronically with this intermediary product. We supposed that if the β-hydroxybutyrate would attack the *B*-cells directly, then even in the absence of the pituitary gland (absence of adrenocorticotrophic hormone) the diabetogenic effect would still take place. But if the pancreas remains intact, that is to say, if the symptoms described above do not appear, then we can assert that this diabetogenic effect of β-hydroxybutyrate is not a primary one, but is mediated by the pituitary gland.

Our results (Table 2) with the hypophysectomized rats after a chronic treatment with sodium β-hydroxybutyrate show an oscillation of the plasma insulin values, but within normal limits. Glycæmia also shows an increase but of little importance. Histologically no destruction of the *B*-cells was observed even after a longer treatment.

We then treated a series of hypophysectomized rats with sodium β-hydroxybutyrate + adrenocorticotrophic hormone (0·5 μgm./100 gm.). In these animals the plasma insulin value decreased, some hyperglycæmia occurred, and the histological aspect of the *B*-cells showed signs of partial atrophy in general. It must be emphasized that though the β-hydroxybutyrate + adrenocorticotrophic hormone, in the absence of hypophysis, provoke diabetic signs, they are less important than those observed in normal animals.

Table 2. EFFECT OF THE CHRONIC TREATMENT WITH SODIUM β-HYDROXYBUTYRATE UPON HYPOPHYSECTOMIZED ANIMALS

No.	Days of injections	Glycæmia (mgm. per cent)	Insulin in plasma (microunits/ml.)	Adrenocorticotrophic hormone in plasma (milliunits/100 ml.)
1	0 (control)	88	44 ± 4	0 0 ± 0 0
2	7	91	66 ± 1 3	—
3	14	90	49 ± 7	—
4	28	118	71 ± 11	—
5	35	101	31 ± 6	—
6	42	87	91 ± 8	—

Table 3. EFFECT OF THE SODIUM β-HYDROXYBUTYRATE + ADRENOCORTICOTROPHIC HORMONE TREATMENT ON HYPOPHYSECTOMIZED ANIMALS

No.	Days of injections	Glycæmia (mgm. per cent)	Insulin in plasma (microunits/ml.)	Adrenocorticotrophic hormone in plasma (milliunits/100 ml.)
1	0 (control)	78	60 ± 10	0 0 ± 0 0
2	7	130	120 ± 21	—
3	14	127	150 ± 11	—
4	28	140	99 ± 0	—
5	35	121	60 ± 8	—
6	42	154	40 ± 1	—

We therefore conclude that: (1) Chronic treatment with sodium β-hydroxybutyrate produces a diabetic state in normal animals, but the effect is not a direct one; it takes place via the hypophysis. (2) The consequences of the chronic treatment with this product are very similar to those obtained by us with a longer treatment with adrenocorticotrophic hormone. (3) The diabetic effect upon the hypophysectomized animals treated with sodium β-hydroxybutyrate has not the importance initially supposed. The sodium β-hydroxybutyrate leads to mobilization of adrenocorticotrophic hormone and there may be hypersecretion of other diabetogenic factors (somatotrophic-hormone); and thus in the absence of the pituitary gland, even in the presence of exogenous adrenocorticotrophic hormone, the diabetic signs are less significant. (4) The diabetogenic effect of the sodium β-hydroxybutyrate as well as of the adrenocorticotrophic hormone are diminished in the absence of the pituitary gland.

Vasodepressor Effect of Adenosine Phosphates and 5′-Adenylmethylenediphosphonic Acid, an Analogue of Adenosine Triphosphate

MEMBERS of the adenosine, adenosine monophosphate, adenosine diphosphate and adenosine triphosphate series produce a marked vasodepressor effect in the cat anæsthetized with nembutal. In this series, as the number of phosphate groups in the 5′ position is increased, the vasodepressor effect is also increased[1].

Two general hypotheses as to the order of potency in the members of this series may be considered. In the first, cleavage of the polyphosphate side-chain is postulated with or without transfer of phosphate to a substrate or active site. The high activity of adenosine triphosphate in dilating the coronary arteries in the dog led Winbury *et al.*[2] to suggest that "bond energy may serve to trigger some biochemical process leading to greater dilatation".

Alternative explanations for the mechanism of the action of members of this series, which would not involve 'high-energy' bond cleavage, might be found in the complexing or binding capacity of these

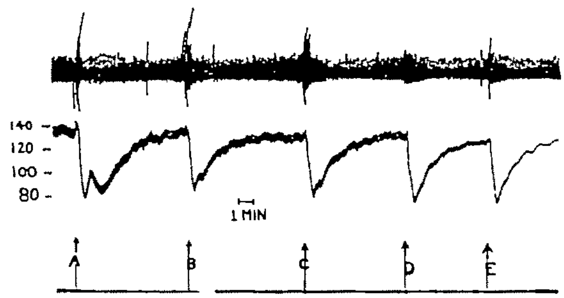

Fig. 1. Respiration (upper) and arterial blood pressure in mm. mercury (lower) tracings from a 2 kgm. cat (male) anæsthetized with nembutal. The letters indicate intravenous injection of the following: (A) 1 µmole analogue; (B) 4 µmoles adenosine monophosphate; (C) 4 µmoles adenosine monophosphate; (D) 2 µmoles adenosine triphosphate; (E) 2 µmoles adenosine triphosphate

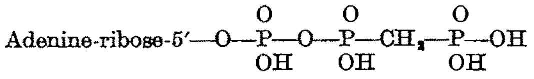
compounds. Martell and Schwarzenbach[3] have shown that the association constants of the members of this series, with magnesium and calcium complexes, increase with the number of phosphate groups. Thus the vasodepressor activity appears to parallel the change in association constants of these compounds.

The present preliminary report describes the results obtained in comparing the vasodepressor effect of adenosine monophosphate and adenosine triphosphate with 5′-adenylmethylenediphosphonic acid, a phosphonic acid analogue of adenosine triphosphate (this compound has been prepared and characterized by us; details will be given elsewhere).



$$\text{Adenine-ribose-5}'\text{—O—}\overset{\text{O}}{\underset{\text{OH}}{\text{P}}}\text{—O—}\overset{\text{O}}{\underset{\text{OH}}{\text{P}}}\text{—CH}_2\text{—}\overset{\text{O}}{\underset{\text{OH}}{\text{P}}}\text{—OH}$$

5′-adenylmethylenediphosphonic acid

Experiments were performed on thirty-one cats anæsthetized with nembutal. The carotid blood pressure was recorded with a mercury manometer on a kymograph. Adenosine mono- and tri-phosphate and the analogue were administered intravenously in 0·9 per cent sodium chloride.

Fig. 1 illustrates the results obtained in a cat anæsthetized with nembutal, in which the magnitude of the vasodepressor response is about the same for each of the doses used. The relative potency of the analogue varied from 1·2 to 4·2 times that of adenosine triphosphate in these experiments, with a mean value of 2·3 for 31 such comparisons.

Adenosine monophosphate was found to have a relative potency of 0·22–0·50 that of the triphosphate, with a mean value of 0·33.

The methylene group in place of the pyrophosphate oxygen of adenosine triphosphate results in an increase in vasodepressor activity. This indicates that the terminal pyrophosphate group of the triphosphate is neither necessary for activity nor for enhancement of activity. It is well established that the phosphonic acid (C–P bond) is markedly resistant to chemical cleavage[2,4]. Additional evidence of this resistance to cleavage was seen when the analogue was substituted for adenosine triphosphate in the yeast hexokinase reaction, which reaction has been proved to take place with the cleavage of the adenosine triphosphate terminal pyrophosphate bond[5]. The analogue failed to serve as a substitute for adenosine triphosphate in this reaction. Since the similarity of the pharmacological effects of adenosine triphosphate and its phosphonic acid analogue are striking, this also suggests that cleavage of the terminal pyrophosphate bond is not essential for the production of the vasodepressor effect by adenosine triphosphate. The possibility that the analogue may owe its activity to cleavage of the second pyrophosphate bond, giving rise to adenosine monophosphate and methylenediphosphonic acid, which in turn produces the observed response, seems unlikely since these compounds given together show much less activity than the analogue.

Considering the results reported here, the mechanism of action of the series of compounds may be due to binding to the receptor site without a cleavage of the chain. The activity of the analogue could be accounted for in this manner; that is, binding to the receptor site without cleavage of the chain. The increase in activity of the analogue in comparison with the other compounds may result from a greater affinity for this receptor site.

Effect of Different Types of Milk on Intestinal Motility

IN conditions of infantile diarrhœa restriction of milk from the diet causes rapid improvement of the condition: if the milk diet is resumed too early, the symptoms rapidly appear again. This shows that, most probably, there is a relation between the milk and the symptoms of infantile diarrhœa. It may be that in the milk there are factors which stimulate the motility of the small intestine and thus cause its rapid evacuation.

It was found by Becovic and Moglajile[1] that mare's milk contains acetylcholine. This was shown by studying the effect of milk on the isolated frog's heart and the small intestine of the dog prepared *in situ* according to the method of Straub and Triendler. The effects of human milk and the different types of milk obtained from Egyptian dairy animals on the intestinal motility *in vitro* were therefore examined. Fresh milk, stored milk, skimmed milk and pasteurized milk were used.

The jejunum of freshly killed rabbit of about 1 kgm. body-weight was excised. Isolated pieces of jejunum of about 3 cm. in length were suspended in an organ bath of about 10 ml. volume containing oxygenated Tyrode's solution maintained at 37° C. The movements of the longitudinal muscle were recorded by a lever. The normal action and the effect of adding a few drops and 2 c.c. of different types of milk were compared. When the milk showed an excitatory response, its effect was studied on an atropinized loop of intestine.

Fresh milk was collected from the animal by hygienic methods and was immediately examined.

Fresh cow's milk. A few drops had no effect on the intestinal motility. When 2 c.c. of the milk (at 37° C.) were added to the intestinal bath, it caused temporarily slight inhibitory effect after which the intestinal motility gradually increased. Addition of one drop of bellafolin immediately stopped the excitatory effect.

Fresh buffalo's milk. A few drops of the milk added to the intestinal loop caused immediate inhibition of the intestinal motility; this inhibitory effect disappeared very rapidly and the intestine recovered. Addition of 2 c.c. of fresh milk to the intestinal bath caused a marked inhibitory effect, and then the intestine gradually recovered.

Fresh goat's milk. Complete immediate relaxation of the intestinal loop was obtained by the addition of a few drops. A high dose of 2 c.c. produced a similar effect. Recovery gradually occurred.

Fresh human milk. Whether fresh or stored in the refrigerator, human milk had no effect on the motility of the intestinal loop.

The effect of stored milk at room temperature up to 12 hr. or at very low temperature (0° C.) up to 7 days did not cause any change in the behaviour of the intestinal loop.

Pasteurization of milk did not change its effect on the intestinal motility.

The effects of different types of whey were examined.

Cow's whey. Whether in small dose of 5 drops or a big dose of 2 c.c., cow's whey caused a preliminary inhibition followed by strong excitatory effect. One drop of bellafolin immediately stopped the excitatory effect. Cow's whey in high doses did not show the excitatory effect on the atropinized loop.

Buffalo's whey. This produced complete relaxation of the intestinal loop when added even in very small doses.

Goat's whey. The inhibitory effect which was recorded in the case of fresh, stored, and pasteurized goat's milk cannot be shown in case of the whey, but it caused a very strong excitatory effect which is not produced in the case of the atropinized loop.

The preliminary inhibitory effect observed in the case of fresh cow's milk and the maintained inhibitory effect of buffalo's milk were not shown when the milk was previously boiled at atmospheric pressure and then added to the intestinal bath after cooling to 37° C. In the case of goat's milk, boiling did not abolish the inhibition produced.

When the anti-histaminic 'Sandosten' was added to the Tyrode solution in the intestinal bath, the normal effect produced by the different milks were not changed.

The experiments show that different milks have different effects as regards the motility of the intestinal loop *in vitro*. Cow's milk, whether fresh, stored, pasteurized or boiled, had an excitatory effect. The parasympatholytic drug bellafolin abolished this excitatory response. Buffalo's and goat's milk showed a maintained inhibitory effect. As these effects could be observed when the whey was used, the factor concerned with excitation or inhibition of the intestinal loop most probably lies in the whey. Becovic and Moglajile[1] stated that mare's and cow's milk contain acetylcholine, and as the Egyptian cow's milk showed an excitatory effect abolished by bellafolin, so this finding by Becovic and Moglajile can be applied to this milk.

The inhibitory effect produced by goat's milk and buffalo's milk may be due to an inhibitory factor, the nature of which is not yet settled. As the inhibitory effect was abolished by boiling in the case of buffalo's milk, but was not affected by boiling in the case of goat's milk, this indicates that the nature of the inhibitory factor differs in the different milks.

Human milk had no effect at all on the intestinal motility. This may be due either to the absence of such excitatory or inhibitory factors, or they may be present in concentrations antagonizing each other.

The study of the effect of the different amino-acids present in milks and the nature of the excitatory and inhibitory factors is under investigation in our laboratories.

Hormonal Control of Secretion in the Oviduct of the Amphibia

Galli-Mainini[1], Houssay[2] and Allende[3] have shown that secretion by the glands of the oviduct in *Bufo arenarum* is controlled by a dual mechanism: a prolactin-like hormone from the anterior pituitary acts directly on the oviduct, and a progesterone-like hormone produced in the ovary during ovulation causes secretion independently of the direct pituitary action. In view of the importance from the evolutionary point of view of this demonstration of the action of a progestational hormone at the level of the Amphibia, it was thought desirable to extend the work to include the two British species, *Bufo bufo* and *Rana temporaria*.

In the first series of experiments various concentrations of progesterone ('Progestin' B.D.H.) in 0·2 ml. arachis oil were injected into the lumina of the doubly ligatured left oviducts of ovariectomized frogs and toads[3]. In all experiments using toads the anterior lobe of the pituitary had been removed at least two days previously. 48 hr. after injection the animals were killed, and, after weighing the oviduct and measuring the length enclosed by the two ligatures, the gelatinous secretion within the oviduct was removed and weighed. The results were expressed as the ratio of the weight of secretion in mgm. (after correcting for the weight of oil injected) to the length of oviduct between the ligatures in cm. This expression is termed the quotient of secretion[1,3]. The quotient is numerically smaller in the frog, because, unlike the condition found in the toad, there is no clear differentiation of the oviduct into two parts and it was necessary to use the whole length of the oviduct if the quotients from different animals were to be comparable.

The response to progesterone is shown in Table 1, where a highly significant increase in the quotient of secretion was given by 0·1 mgm. of progesterone.

Table 1. SECRETION BY THE GLANDS OF THE OVIDUCTS OF FROGS AND TOADS IN RESPONSE TO PROGESTERONE OR AN EXTRACT OF OVULATING OVARIES. FIGURES IN BRACKETS DENOTE THE NUMBER OF ANIMALS IN EACH GROUP

Treatment	*Rana temporaria*		*Bufo bufo*	
	Quotient of secretion ± *S.E.*	*P**	Quotient of secretion ± *S.E.*	*P**
0·2 ml. arachis oil in lumen of oviduct	6·07 ± 0·79 (12)	—	12·8 ± 0·996	—
0·5 mgm. progesterone in lumen of oviduct	13·1 ± 3·37 (10)	< 0·03	—	
0·1 mgm. progesterone in lumen of oviduct	12·9 ± 2·36 (7)	< 0·01	40·1 ± 5·32	< 0·001
0·1 mgm. progesterone in dorsal lymph sac	—		41·02 ± 5·18 (9)	< 0·001
0·2 ml. ovary extract in lumen of oviduct	—		29·4 ± 8·11 (8)	< 0·05

* Values of *P* for comparison of experimental groups with arachis oil controls (using right-hand tail '*t*' test).

In the frog increasing the dose to 0·5 mgm. did not appear to promote further secretion. In the toad a very similar response was obtained whether the progesterone was injected directly into the oviduct or into the dorsal lymph sac.

In another series of experiments twelve toads were each injected with 1,000 I.U. of chorionic gonadotrophin ('Pregnyl') and killed 48 hr. later when the animals were in various stages of ovulation. The ovaries were removed, dried at 37° C. for 24 hr., then ground up in a mortar with sand and extracted with ether in a Soxhlet apparatus. 0·2 ml. portions of the clear oil obtained after evaporating off the ether were injected into the ligatured oviducts of ovariectomized and hypophysectomized toads as in the progesterone series. Table 1 shows that this extract gave a higher mean quotient of secretion compared with arachis oil controls, though there was considerable variation in the responses of the assay animals.

These experimental results agree closely with the more detailed work by Houssay and his co-workers on *B. arenarum*, and suggest that the production by the ovary during ovulation of a hormone having a stimulating action on the glands of the oviduct may be a general characteristic of the Amphibia.

PLANT PHYSIOLOGY

Response of Growing Plants to a Uniform Daily Rotation

PLANTS under various fixed conditions of light, temperature, and humidity have been turned continuously about a vertical axis at the rate of one revolution a day. The results suggest that the plants used are sensitive to the direction of rotation; a rotation which is clockwise when viewed from above inhibits growth, anti-clockwise direction stimulates growth. As the finding may be useful background to a study of the twining of plants, the initial results are being reported.

Cyclamen. In subdued daylight, or in artificial top lighting, plants which were made to rotate clockwise showed, after two or three days, a loss of turgidity in some of the leaves, which yellowed and died as the experiment continued. Plants turned anti-clockwise were as healthy and turgid as stationary ones.

Scarlet Runner Beans. Beans which normally twine anti-clockwise were found not to twine around their supports when growing plants and their supports were rotated anti-clockwise at one revolution a day under fixed side-lighting with tungsten lamps. Plants which were turned clockwise began to twine but lost turgidity, and some leaves yellowed and died. When these plants were transferred at an early stage of reaction to anti-clockwise movement they showed partial or full recovery.

Oats. Husked oats (variety Milford), were pre-chilled in tap-water at 5° C. for 48 hr. The seed was then sown, groove side down, on moist filter paper in a covered dish, and held at 20° C. in darkness. After 24 hr., germinated seedlings were transplanted on to 4-in. diameter perforated plastic holders over tap-water. Each holder and dish (48 seedlings per holder) was transferred to a completely dark, controlled-climate cabinet provided with a suitable set of turntables to give clockwise and anti-clockwise rotations. Cabinet temperature was controlled to 1° C. and relative humidity to 1 per cent. In successive experiments the controlled temperatures ranged from 25° C. to 28° C. and the relative humidity 85–95 per cent. After 5 days, the lengths of coleoptiles and roots were measured. In every experiment the mean lengths under each treatment were expressed as a percentage deviation from the mean of the stationary plants. The average deviations throughout nine experiments were as follows:

Clockwise	Coleoptiles	− 6·1	per cent
	Roots	− 8·6	,,
Anti-clockwise	Coleoptiles	+ 5·6	,,
	Roots	+ 10·2	,,

In individual experiments the means of the clockwise-rotated sets of plants were always smaller than those of the stationary, and the anti-clockwise in all cases larger (for example, for coleoptiles—clockwise 42·7 ± 0·8 mm., stationary 46·3 ± 0·7 mm., anti-clockwise 48·2 ± 0·9 mm.).

The subject of diurnal rhythms as affecting the above is being considered.

Energy-trapping Centres in Photosynthesis

IN opaque specimens of packed *Chlorella* cells, the quantum yield of red fluorescence varies with the wave-length of the exciting light[1]. From a maximum value measured at the absorption peak at wave-length 675 mμ, decreases to about 70 per cent of this value occur at shorter wave-lengths, as shown in Fig. 1. In contrast, dilute suspensions with measured true absorption give a relatively constant yield, suggesting that competitive selective scattering and re-absorption losses are largely responsible for the yield decreases observed in opaque specimens.

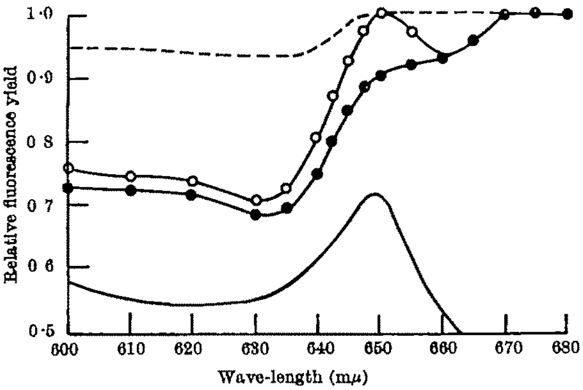

Fig. 1. Dependence of the relative fluorescence on the excitation wave-length and intensity in *Chlorella*. – – – –, Thin suspension; ○——○, opaque specimen (high intensity); ●——●, thick specimen (low intensity), ———, difference spectrum produced by intensity (ordinate × 2)

It has now been found that a part of the effect depends on the light intensity employed in yield determinations. High-intensity light produces a relatively more constant yield compared with low intensities, and the spectral dependence of the relative yields of *Chlorella* at different levels of illumination are included in Fig. 1. The absolute fluorescence yield at high-intensity excitation was 3–4 times greater than at low light levels. Since no changes in absorption or fluorescence spectra larger than 1 per cent occurred during these measurements, the difference spectrum corresponding to the selective increase in yield must be produced by a change in the effective fluorescence yield of a component pigment. The similarity in position of the difference spectrum maximum, shown in Fig. 1, to that of chlorophyll *b* *in vivo* suggests the involvement of this pigment. Before discussing the significance of this observation, it is necessary to consider the different situations of chlorophylls *a* and *b* in relation to energy transfer. Assuming that this process is responsible for energy migration to photochemically active trapping centres present in relatively small concentration, then these centres must contain a non-fluorescent pigment with an absorption band overlapping the fluorescence band of chlorophyll *a*. Changes in the trapping efficiency, accompanied by inverse changes in fluorescence yield, can occur in two ways if the geometry of the system remains constant. A change in absorption in the trapping pigment could reduce energy acceptance, or alternatively, the trapping pigment can become fluorescent. The absence of considerable absorption and fluorescence spectral changes means either that the trapping pigment is present in such small concentration that its absorption changes are undetected or that it is chlorophyll *a* itself or a spectroscopically similar molecule. The reported similarity of the fluorescence and delayed-light spectra[2] observed in *Chlorella* supports the involvement of chlorophyll *a*. On this latter basis, the simplest model for a trapping centre would be a complex between chlorophyll *a* and a colourless acceptor molecule, capable in its ground-state of quenching the chlorophyll singlet excited state, being itself converted to a metastable, chemically active form. Providing the ground-state interaction of the components is small, the associated spectral changes will be also small, as they are in chlorophyll *a* quenching by complex formation with aromatic nitrocompounds and quinones[3].

Detectable spectral shifts occur with chlorophyll *b* however, and some *in vivo* measurements of absorption changes in illuminated *Chlorella*[4] may be relevant in this connexion. During the life-time of the metastable form, the associated chlorophyll molecule could fluoresce normally. Calculation indicates that about 3 per cent of the total chlorophyll, complexed in trapping centres, would receive by resonance transfer at least 75 per cent of all absorbed quanta, the balance appearing as heat or fluorescence. In the trapping centres described, chlorophyll *b* might replace chlorophyll *a* in some instances. Few transfers among chlorophyll *b* molecules can occur *in vivo*; because of the relatively lower concentration of this pigment, and the large overlap of its fluorescence band with the absorption peak of chlorophyll *a*, excited chlorophyll *b* always transfers directly to chlorophyll *a*. As a consequence, that fraction of chlorophyll *b* which does not sensitize fluorescence must consist entirely of quenched molecules. This fraction corresponds to about 10 per cent of the whole absorption at 650 mμ, or to about 25 per cent of all chlorophyll *b*, which contributes roughly 40 per cent to the total absorption at this wave-length. The transfer processes occurring between the chlorophyll types can be shown in the following scheme:

$$\begin{tikzcd}
b \arrow[rr] & & {[a]} \arrow[rr] \arrow[dr, "\bar{n}"] & & \text{Fluorescence} \\
& b.T^{*} \arrow[ur] & & a.T \to \text{Photosynthesis} & \\
& & b.T \to \text{Photosynthesis?} & &
\end{tikzcd}$$

where T and T^{*} represent the acceptor molecule in the ground and metastable states, respectively, and $\bar{n}$ is the average number of transfers among chlorophyll *a* molecules before trapping. A feature of this scheme is that at high intensities of excitation both types of chlorophyll *b* molecules sensitize chlorophyll *a* fluorescence and photosynthesis. The negligible overlap of chlorophyll *a* fluorescence with chlorophyll *b* absorption prevents the quenched fraction of this pigment from trapping chlorophyll *a* fluorescence. If this overlap is not negligible, however, a scheme requiring only chlorophyll *b* trapping centres could be proposed. The possibility that the chlorophyll *a* and *b* trapping centres may be shared or photochemically different is suggested by recent reports of the effect of supplementary light on photosynthesis[5]. In addition, the fall in photosynthetic yield in *Chlorella* which is observed at certain wave-lengths[6] and is usually attributed to inactive carotenoid absorption, could equally well be attributed to an inactive fraction of chlorophyll *b*, as was indeed suggested by Emerson.

BIOLOGY

An Automatic Fish Egg Counter

The fecundity of fish has hitherto been generally determined by making direct counts of weight or volume sub-samples of the total gonad contents. These counts are then raised by the ratio of the total weight or volume of the gonad contents to the sample weight or volume.

This process is very time-consuming, and, in consequence, routine studies of the fecundity of large numbers of fish have not been practicable. While typical fecundity estimates have been obtained for a large number of fish species, using material classified by size and age, and collected in one or two seasons, no detailed long-term investigations have been conducted. Such investigations could be of considerable value in studies of the biology and population dynamics of fish populations where it is desired to know the changes in fecundity from year to year, the factors determining these changes, and the dependence of recruitment and strength of year-class on these changes.

To meet this need for routine measurement of fecundity (in the first instance of herring) an apparatus has been devised here. This makes rapid counts of all the eggs in a gonad, thus eliminating the tedious work of hand-counting, and also eliminating the errors of sub-sampling.

The apparatus is shown diagrammatically in Fig. 1. This shows that the eggs are drawn in a stream of water through a constricted tube, interrupting a beam of light which is directed through it. The light beam falls on the cathode of a photomultiplier tube, and the interruptions of the beam are recorded on an electronic counter.

The constricted tube, or counting chamber, has a minimum internal diameter of 1·53 mm., and it has been found that this is just large enough to pass the largest herring eggs without causing frequent stoppages.

The photomultiplier tube used is an 'R.C.A. type 931*A*' with nine dynodes, and the light source is a 2·2-V. 0·25-amp. lens-end flash-light bulb. The counter is a 'Panax type *D*554' which conveniently supplies the E.H.T. for the photomultiplier (roughly 200 μamp. at 1,000 volts) and an a.c. supply for the light source.

As will be seen from Fig. 1, a flow of bubble-free water is maintained from a constant-head tank through the counting chamber. Eggs to be counted are first cleared of all connective tissue and placed in water in the large glass funnel, and the stirrer speed is adjusted to bring them into suspension. The tap at the base of the funnel is then opened, and the eggs sink slowly downward and are swept through the counting chamber. The rate of sinking, and so the counting-rate, can be adjusted by varying the speed of the stirrer. In practice, a counting-rate of about 100 per sec. is found to be best. Attempts to increase this rate generally result in blockage of the system.

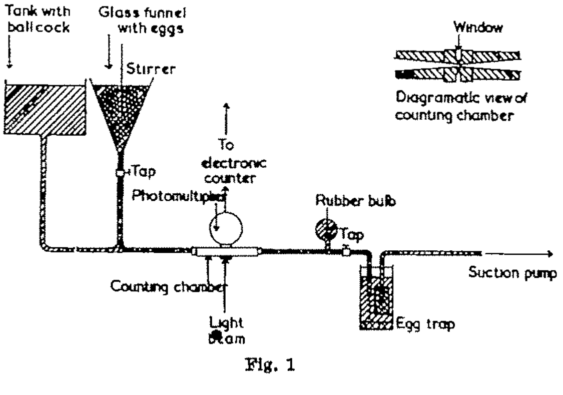

Fig. 1

A considerable number of trials have been made to gauge the accuracy and consistency of the counts. Typical sets of results are shown in Table 1, which gives small successive counts of samples of known size, and in Table 2, which shows successive counts of large samples.

Table 1

Sample	Actual number of eggs	No. recorded by counter in successive trials			
		1	2	3	4
1	521	521	519	525	523
2	778	775	777	771	770
3	507	505	505	505	503
4	808	805	803	801	800

Table 2

Sample	No. of eggs recorded by counter		
	1	2	3
1	19,088	19,128	19,101
2	25,093	25,135	25,274
3	39,494	39,513	39,596
4	43,106	43,150	43,279

These results show that the maximum discrepancy between counts and the maximum error on known samples does not exceed 1 per cent. It is thus felt that reliance can be placed on the method, and a programme of routine investigations of herring fecundity is being developed accordingly.

A Pale Hag-fish

De Graaf[1] and more recently Ewer[2] have described specimens of *Xenopus laevis* lacking hæmoglobin. In the course of an investigation on the physiology of the heart of the cyclostome *Myxine glutinosa*, I found on August 20 an animal about 25 cm. long which was remarkably pale, except in the caudal and dorsal regions, which were grey. Its blood appeared to have no pigmentation due to hæmoglobin except near the gills, where there were some small localized red areas. All the blood vessels were cream in colour as well as the heart, although the ventricle might have been pink (? myoglobin, cytochromes). The liver was dark green and after fixation in 8 per cent formol the principal dorsal vessels showed a light greenish coloration due perhaps to the destruction of hæmin compounds. As for the gall bladder, it did not appear greener than normal.

When first observed, the animal was in the dark in circulating sea water at 15° C. among a mixture of hag-fish, and showing as much vitality apparently as the other animals; it is particularly interesting to emphasize that this specimen had been caught at the same time as the others, two days before, in the Gullmars Fjord, Sweden, using G. Gustafson's technique, that is, by means of a large bottle containing some pieces of mackerel. Thus this animal, which is very poor in respiratory blood pigments, shows normal habits of feeding, proving that its olfactory organs were in good physiological condition. Hence the pathological state of the blood of this hag-fish leads one to ask what is the limiting role which could be taken by hæmoglobin in the life of *Myxine*.

My thanks are due to Dr. Swedmark, director of the Kristinebergs Zoologiska Station, Fiskebäckskill, Sweden, for providing many living hag-fishes.

Interlaminate Figures of Sessile Barnacle Shells

Alessandri[1], Gruvel[2] and Davadie-Suaudeau[3], in their works on the cirripedes, have directed attention to figures or patterns in the shell plates of various species of sessile barnacles, and further work may prove these to be an important taxonomic characteristic for species identification; but this seems to have been somewhat neglected.

The usual method of identifying barnacles is often difficult due to the variability of the shell configurations and must frequently be followed by examination of the soft parts—a tedious undertaking. Even then, mistakes in naming have occurred, but work by Cornwall[4-6] on many specimens has shown that the 'interlaminate' figures are specific and constant for recent and fossil barnacles.

The following method of revealing the figures is a modification of the procedure using plaster of Paris as described by Cornwall. Whole specimens or plate fragments are embedded in 'N.H.P.' mounting plastic (obtained from North Hill Plastics, Ltd., London). Rings of tubular rubber, polythene or cardboard are cut to fit the size of the specimen to be mounted. The rings are placed on a glass plate to which is applied a thin coating of 'Vaseline' and the specimen carefully placed, basis downwards, within the ring. A small amount of the plastic powder ('N.H.P. 2031/19') is spread over and around the specimen and thoroughly wetted with the plastic fluid ('N.H.P. 1844'). When the first application of liquid has been absorbed a fresh portion of powder, followed by more liquid, is added. This procedure is repeated until all, or as much as is thought necessary, of the specimen is covered. Leave to dry and harden (30–60 min.). When complete specimens are to be mounted it is advisable to fill the shell cavity with plastic by turning the mounting ring over and repeating the above process. When ready, the embedded specimen is extruded from the ring or, if this proves impossible, it is cut away and is ready for grinding and polishing.

It is necessary, in order to show the figures to their best advantage, to ensure that the surface to be examined is as flat and even as possible. A coarse grinding is done on a glass plate with wet 320 silicon carbide powder followed by a similar grinding on a second plate with 700 powder. Grinding should be done until the parietal canals are visible. This can be controlled by examining the ground surface at intervals with a hand lens. After grinding, the surface is given a rinse with water to remove any adhering carbide particles and then dried by pressing on to a filter paper. Polishing is done with diamond paste on a chamois leather followed by a final buffing on a dry chamois leather.

The figures are best seen at a magnification of between 20 and 50 with the light from the top and slightly to the side of the mounted specimen. A few drops of water or benzyl alcohol[5,6] run on to the prepared surface between a cover-slip will often help reveal figures which tend to 'disappear' when the mount is dry. Orienting the specimen to the light is also a help in showing up details of the figures. One of the great advantages of the method outlined above is that the mounted specimen can be dissolved out of the plastic mount by steeping in chloroform, when it can be retrieved intact except for the small portion which has been ground away.

Certain species such as *Balanus balanoides* and *Elminius modestus* have not shown any figures in preparations from the basis. This may be due to the fact that these species do not have any parietal canals (Crisp, D. J., personal communication). It may be that such species will show figures if preparations are made from the ala of the wall plates[6].

An atlas of the interlaminate figures from identified barnacle specimens would be of great value for the further identification of species and would help in furthering this work.

Seed Incompatibility in *Primula*

When diploid and autotetraploid plants of *Primula veris* are artificially crossed reciprocally, fertilization occurs and seed is set, but the seed is bad and germination is nil; the same is true for *Primula vulgaris* and *P. elatior*. Similar seed incompatibility (as it may be called) between diploids and their colchicine-induced autotetraploids has been reported in several other genera of flowering plants, for example, *Gossypium*[1] and *Galeopsis*[2]; it is associated with post-fertilization breakdown of the seed tissues, in particular the endosperm. On the other hand, in some genera, for example, *Beta*[3], the crosses are easily made and viable triploids can be produced in large numbers. The reasons for these different types of behaviour are not known, but they are probably connected with differences in the nature and mode of functioning of the tissues concerned in the nutrition and protection of the embryo; it is worth noting that these tissues (the endosperm and the maternal nucellus and endothelium) generally differ in genetic constitution both from the embryo and also from one another.

The seeds produced in the reciprocal diploid–tetraploid crosses in *Primula* are of two types, according to the direction of the cross; similar contrasting seed types are found in a number of diploid interspecific crosses in this group[4]. This is shown in Table 1, where the *P. elatior–P. veris* cross is used as an illustration.

In these crosses, type *A* seed is very small, with abnormally thick integuments, a small amount of

Table 1

♀ parent		♂ parent	Seed type
P. veris (2*n*)	×	*P. veris* (4*n*)	*B*
P. elatior (2*n*)	×	*P. veris* (2*n*)	*B*
P. veris (4*n*)	×	*P. veris* (2*n*)	*A*
P. veris (2*n*)	×	*P. elatior* (2*n*)	*A*

endosperm, which usually degenerates, and a small, often persistent embryo. Type *B* seed is of normal size; the integuments are thin, and the endosperm and the minute embryo degenerate soon after fertilization. Both types of seed are usually nearly empty at maturity and often the seed walls collapse; (very rarely a viable diploid hybrid may be produced from the *veris–elatior* (type *A*) cross[5]). The classification of the seeds into types *A* and *B*, originally based on seed dissection, is fully supported by detailed embryological investigation of their development and breakdown; so that the two pairs of crosses described in Table 1 may be regarded as analogous. In one, seed incompatibility is presumably conditioned by the qualitative gene differences between the two diploid species, and in the other by the quantitative gene differences between the diploid and the autotetraploid.

In previous work on the diploid crosses[4], this analogy led us, following the work of Stephens on *Gossypium*[1] and Howard on *Nasturtium*[6], to think of the genomes of the species in terms of 'genetic strength', and to assign to each genome a numerical value, the genetic value. The results of reciprocal interspecific crosses could then be interpreted in terms of the ratio of the genetic values of the various tissues of the seed, these ratios being different in any one pair of reciprocal crosses. The ratio of the genetic value of the endosperm to that of the maternal tissues has in fact been thus used in interpreting segregation, in interspecific hybrids, of the genes controlling seed incompatibility[7]. In this interpretation, the genetic value of *P. elatior* was set at unity and that of *P. veris* at 1·8, to conform with the fact that the degree of incompatibility in the *elatior–veris* crosses was slightly less than that in diploid–autotetraploid crosses; in the latter, it is assumed that the ratio of the genetic values of the parents is always 1 : 2.

The analogy between the two types of cross can be tested by making reciprocal crosses between the autotetraploid *P. elatior* with a genetic value of 2, and diploid *P. veris* with a genetic value of 1·8. The values of the parents are thus approximately equal, so that theoretically the cross should produce good seed and viable triploid hybrids in either direction; the seeds should tend to type *A* when *P. elatior* (4*n*) is the female parent and to type *B* in the reciprocal. In fact the cross *P. veris* (2*n*) ♀ × *P. elatior* (4*n*) ♂ gives a fair yield of good seeds; germination percentages up to 67 per cent have been recorded, and the hybrids are triploid. Embryological study shows that these seeds are, as expected, of a moderate type *B*; there is a fair amount of endosperm, which shows some abnormalities. On the other hand, the reciprocal cross, *P. elatior* (4*n*) ♀ × *P. veris* (2*n*) ♂, produces rather small seeds, practically empty at maturity, which embryological investigation shows to be of an unexpectedly extreme type *A*, with very thick integuments; and no viable hybrids are produced.

It may be concluded that some at least of the genetical differences which control seed incompatibility between *P. elatior* and *P. veris* are analogous to those between diploids and autotetraploids, and are of a quantitative nature; thus they may be duplications, either of genes or of small chromosome segments. Over and above these differences, however, are others of a qualitative kind; the fact that the reciprocal crosses between *P. elatior* (4*n*) and *P. veris* (2*n*) give such strikingly different results, even though their genetic values are approximately equal, suggests that the qualitative genetic differences may have a cytoplasmic as well as a nuclear component.

A full account of this work is in preparation.

Induction of Traps of Nematophagous Fungi using *Panagrellus redivivus*

FOLLOWING the revived interest in biological control of plant-parasitic nematodes through use of nematode-trapping fungi, much attention is being devoted to collection, identification and economic utilization of these ubiquitous microfloræ.

One conventional method of isolating these forms involves addition of suitable mycogenous material to maizemeal agar. Following a suitable period of growth, during which time fruiting structures are produced, nematode-trapping devices such as adhesive mycelial meshes or knobs, and constricting rings may be in evidence. In such instances the fungus either has been able to form such traps exclusive of the presence of nematodes or else a suitable number of free-living nematodes were present in the mycogenous material and thus stimulated trap formation. In certain cases, however, an external source of nematodes must be utilized in order to provide sufficient impetus for these fungi to exhibit their predacious devices.

Drechsler[1] used additional putrescent material such as friable leaf mould for supplying nematodes to cultures. Comandon and de Fonbrune[2] used sterilized free-living soil nematodes, while other workers employed animal parasitic nematodes[3,4]. Plant-parasitic eelworms such as *Heterodera rostochiensis*[5] and *Ditylenchus dipsaci*[6] also have been used successfully. Duddington[7] found that enormous numbers of free-living nematodes could be reared on rabbit dung infusion agar, but admitted that "One of the major difficulties in working with predacious fungi is maintenance of adequate stocks of eelworms for use when they are required"[8].

During the past two years the nematode *Panagrellus redivivus* (L.) Goodey, 1945, has been utilized with great success for producing fungal traps in cultured nematophagous hyphomycetes. Following growth of moulds from suitable mycogenous material implanted on maizemeal agar, either a water suspension or a writhing mass of *Panagrellus* is introduced into agar plates. Within a day or two fungal trapping structures usually are manifested in legion. Since reproduction of this nematode is continual and prolific, worms of many sizes are produced, allowing even the smallest of traps to become functional. An adequate supply of eelworms can be maintained constantly on cellulose sponges drenched with potato broth[9] or by use of the oatmeal culture method of Cheo and Tarjan[10]. The latter method, which I have used successfully for several years, involves culture of the worms in an oatmeal – cation exchange resin medium. Once the animals have multiplied sufficiently they will form thickly populated, culture medium-free, curd-like masses on sides of the culture vessel above the medium, which can be readily scraped off for introduction into agar plates. Oatmeal cultures in which worms are established can be stored at 2–5° C. When needed, cultures are warmed to room temperature, resulting in accumulation of nematodes on sides of the culture vessel as referred to above. *Panagrellus* populations can be maintained for years by refrigeration, after establishment on test-tube agar slants.

A Mating-type System in an Acellular Slime-mould

An investigation of the life-cycle of the acellular slime-mould (myxomycete) *Physarum polycephalum* has revealed that a mating-type system exists in this organism, and analysis of this system has been carried out. The existence of mating-types in myxomycetes has previously been suggested by Skupienski[1] as a result of his work on *Didymium nigripes* and *D. difforme*, but the situation was not fully investigated.

The spores of *Physarum polycephalum* release uninucleate amœbæ which, after a variable number of divisions, fuse in some unknown way to form the acellular, multinucleate plasmodium. The plasmodium increases in size and, under suitable conditions, produces spores.

A plasmodium, kindly supplied by Dr. Rusch of the University of Wisconsin, produced spores from which a series of cultures was started. Ten out of twenty-five such cultures grown from groups of spores produced plasmodia, but none of twenty cultures grown from single spores did so. These results are similar to those of Skupienski with *D. difforme*.

Groups of amœbæ from ten single isolated spores were used to set up 55 different cultures: 10 of these cultures were started with amœbæ of the ten groups taken separately, and forty-five started with amœb from all possible combinations of the ten grou taken two at a time. The incidence of plasmodiu formation among these cultures was plotted on chart, and the results indicated that a simple tw type (+/−) mating system was in operation (Fig. The test was repeated twice, and in the combin results of all three tests, plasmodium formati occurred in twenty-one of the twenty-five cultur in which it was expected on the basis of a +/ system, but not in any of the twenty combined-gro cultures in which it was not expected or in any of t ten single-group cultures. The failure to for plasmodia in four of the cultures in which it w expected could be due to factors other than matin type, since it was noticed in all experiments th plasmodium formation is dependent also upon number of external conditions, particularly humidit

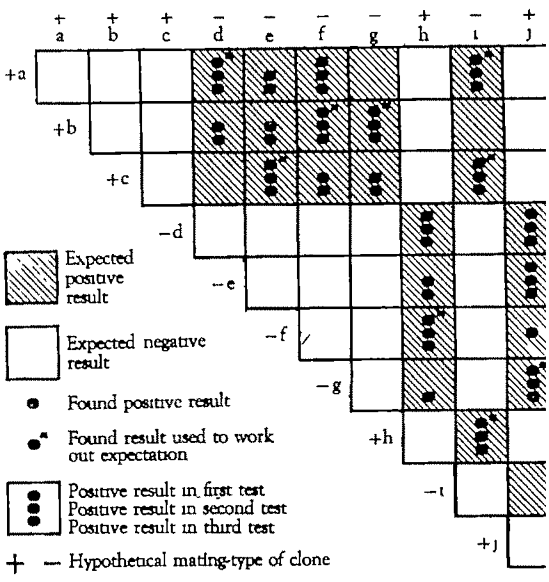

Fig. 1. Tests of the mating-type system. The ten clones were denoted by the letters *a–j*. Each square in the chart represents a culture. Forty-five cultures were started with amœbæ of the ten clones taken in all possible combinations of two at a time, and ten control cultures were started with amœbæ of the ten clones taken separately. The mating-type + or − was assigned to each clone on the basis of nine of the results of the first test. These nine results are marked as shown in the key

It may be concluded from these results that plasm dium formation takes place only when amœbæ different mating-type meet, that only two matin types occur in the cultures investigated, and that spore produces a clone of amœbæ of one mating-ty only.

Investigation of the inheritance of the mating-typ gave the following results. Fifty clones of amœb were established, each derived from a single spore a plasmodium produced by one of the combinatio of two clones described above. Each of these fif first-generation clones was then tested for plasmodiu formation with each of the two parent clones. Fifte of the first-generation clones formed plasmodia wi one parent clone only, ten with the other pare clone only, and twenty-five with neither parei These results are consistent with the hypothesis a simple +/− system. The first-generation clon tested two at a time among themselves gave furth results also consistent with this hypothesis. Howev many of the combinations have failed to produ plasmodia in repeated tests. This suggests, as could be expected, that inherent factors other than mating-type may affect mating and plasmodium formation. While the results are consistent with a two-type mating system, they are not consistent with any of the multifactorial mating-type systems well known in other micro-organisms.

MICROBIOLOGY

Mode of Action of Hair-loosening Organisms

CONSIDERABLE research has been devoted to the development of enzymes for replacing the normal putrefactive techniques for the loosening of wool and hair fibres on animal pelts. Detailed knowledge of the tissues responsible for anchoring the fibre in the skin is therefore essential.

Examination of fibres obtained from skins which have been exposed to bacterial attack shows that the follicle bulb has been completely digested, leaving a tapered root of exposed cortical cells. It is considered that digestion of the root bulb permits the fibre to be readily withdrawn from the skin and that the organisms responsible penetrate down the follicle to attack the soft keratin.

In recent work, however, we have related the appearance of the follicle to the force necessary to withdraw fibres from pelts and have observed that, when the depilation load has fallen to the level at which the fleece is normally pulled from the skin, the whole follicle is removed intact with the fibre. At a later stage of putrefaction, although the depilation load is virtually unchanged, the follicle is rapidly digested to give the typical tapered appearance.

Fig. 1 shows a bundle of intact follicles on fibres pulled as soon as the depilation load had fallen to a level suitable for pulling.

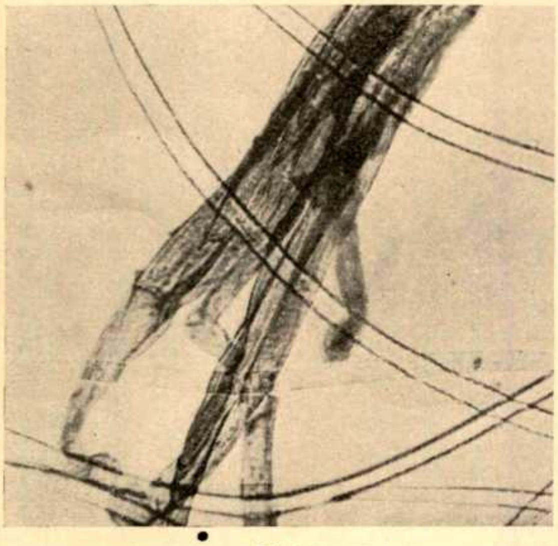

Fig. 1

It seems, therefore, that the bacteria penetrate from the flesh side of the skin to proliferate around the follicles, and that the most significant feature of fibre loosening is the digestion of material in these regions. Whereas efforts have, in the past, been concentrated on the degradation of the soft keratin, the production of an enzyme designed to digest the dermal material immediately adjacent to the follicle would seem likely to result in a greater yield of undamaged fibre.

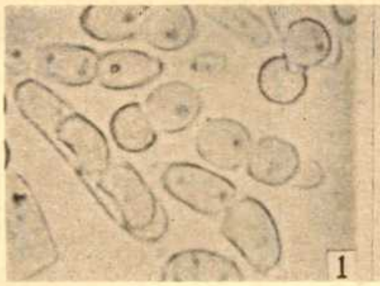
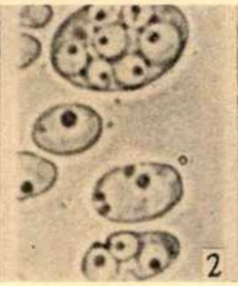
Taxonomy of Yeasts

ON different occasions, when studying the classification of yeasts, I have been able to appreciate how little consistency there is in the taxonomic characters in use. Recently, I have met with fresh anomalies which, in my opinion, make a complete revision of the present system of classification of yeasts unavoidable.

(*a*) From the aqueous solution separated from oil during the manufacture of olive oil, in Spain named 'alpechín', a yeast culture was isolated, *Ac* 11, which is a characteristic *Zygosaccharomyces*, able to produce vigorous alcoholic fermentation and which ferments glucose, galactose, saccharose, melibiose and raffinose completely, and does not ferment or assimilate maltose or lactose. In accordance with the classification of Lodder and Kreger-van Rij[1], this yeast could be considered as a *Sacch. microellipsodes*; however, as to the organism described by Lodder and Kreger-van Rij as a *Sacch. microellipsodes*, is it truly a *Saccharomyces*? The Dutch authors admit that they have not been able to observe spores in the strain under study, and neither could Stelling-Dekker in 1931; moreover, Kudriavtzev[2] categorically denies that the organism is a *Saccharomyces*, not because of its inability to sporulate, but because of its morphology, its weak fermentation of the carbohydrates, etc.; and states that, in his opinion, its place in the classification system is not yet sufficiently clear. Therefore, it is possible that our organism *Ac* 11 corresponds to a *Saccharomyces* species which has not yet been described, for which I propose the name of *Sacch. malacitensis* (from Málaga, the province from which I received the sample of 'alpechín').

Moreover, I had earlier obtained a hybrid[3] crossing *Sacch. oxidans* (ferments glucose, saccharose and raffinose 1/3) and *Sacch. oleaceus* (ferments glucose, galactose, melibiose and raffinose 1/3), to which I gave the symbol *H* 7–4–1; this has a fermentation spectrum identical with that of *Sacch. malacitensis*. Though there are notable differences between the morphology of *H* 7–4–1 and *Sacch. malacitensis*, it would be reasonable to suppose that, were the origin of *H* 7–4–1 unknown, it would be classified as a *Sacch. malacitensis* strain. However, in biology it is inconsistent to consider as a new species an organism obtained by hybridation with other diverse organisms, since a species includes all the potentially interbreeding individuals, the descendants of which are also potentially interbreeding. Therefore the doubt arises whether the present separation of species in the genus *Saccharomyces* is admissible, based as it is fundamentally on the simple difference of fermentation of only one carbohydrate.





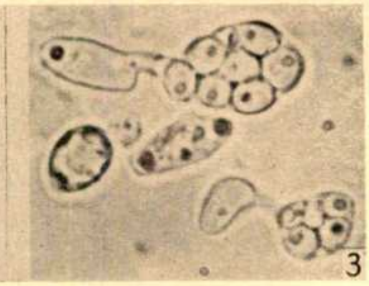


Fig. 1. *Pichia membranaefaciens*, strain *VB* 65 (*T* 109). Asci with bean-shaped spores. From *MA* 29 sporulation medium, after 5 days at 25° C. Unstained. (× 2,000)

Fig. 2. *Pichia membranaefaciens*, strain *Ac* 40. Asci with three and seven spores. From the pellicle formed in malt extract, after 3 days at 25° C. Unstained. (× 2,000)

Fig. 3. *Pichia membranaefaciens*, strain *Ac* 40. Asci with four and seven spores formed after heterogeneous conjugation. From the pellicle formed in malt extract, after 3 days at 25° C. Unstained. (× 2,000)

(*b*) From a sulphurized grape must which began to ferment spontaneously four months after preparation, among other yeasts a culture, *VB* 65 (*T* 109), was isolated, which was a characteristic strain of *Pichia membranaefaciens* but possessed the peculiarity that, as well as the normal spores, it also formed kidney-shaped spores; such spores have never been mentioned in the descriptions of the genus *Pichia*, not even in the very modern one by Phaff[4]. As a rule, great importance is given to the form of the spores as a taxonomic characteristic; for example, Kudriavtzev[2] created the genus *Fabospora* on the basis of its bean-shaped or reniform spores, and established a relation between this spore form and its weak ability for fermenting carbohydrates. Wickerham[7] also, on establishing his new genus *Dekkeromyces*, conceded special importance to the spore form. It appears very difficult to separate my organism from the species *Pichia membranaefaciens*, in which case the taxonomic value of the spore form will be open to controversy.

(*c*) From samples of 'alpechín' obtained from two different parts of the province of Badajoz, two yeast cultures were isolated, *Ac* 40 and *Ac* 47, which are two strains of *Pichia membranaefaciens*; although *Ac* 40 forms only a rather primitive pseudomycelium in anaerobiosis, the new definition of the genus *Pichia* given by Phaff[4] admits species without or with a reduced pseudomycelium. These two strains develop a smooth pellicle in malt after three days at 25° C. and form a large number of asci with 1–4 spores, as well as others with 5, 6 and 7 spores; asci are formed without immediately preceding conjugation or after heterogamous conjugation. These asci have not been mentioned in the genus *Pichia*, so that a revision of the diagnosis of *Pichia* is necessary.

(*d*) From different samples of 'alpechín' obtained from 22 places in different regions of Spain, 28 strains of *Saccharomyces oleaginosus*[5] were isolated. One of these strains, which has characteristics coinciding completely with those typical of the species, nevertheless differs from the remainder in its positive assimilation of potassium nitrate. According to Lodder and Kreger-van Rij[1] and Wickerham[6], yeasts which reproduce asexually exclusively by budding, form 1–4 ascospores per ascus and assimilate nitrate, should be included in the genus *Hansenula*. Nevertheless, in view of the observations mentioned, I doubt whether the assimilation of potassium nitrate can be regarded as a taxonomic characteristic of importance.

A detailed account of this work will be published elsewhere.

Permeability of Dormant Bacterial Spores

THE frequent assumption that bacterial spores are impermeable and thereby metabolically dormant, unstainable and resistant to environmental stress has not heretofore been tested by experiment. We have attempted to examine this problem using clean, dormant, thermostable spores of a common aerobic bacterium, *Bacillus cereus* strain terminalis.

The organism was grown in a liquid semi-synthetic medium to essentially complete and synchronous sporulation[1]. After sporangial autolysis, the free spores were harvested by centrifugation or foam separation and washed repeatedly with distilled water to demonstrable removal of stainable cells and debris, catalase and germinating compounds. The total uptake of exogenous solutes by masses of the clean spores was assessed by the 'space' technique, the details and formulations of which have been described previously[2]. This procedure involves the addition of a known volume and concentration of solute to a known large mass of cells; after mixing and repacking the cells, the uptake is determined from the degree of dilution of the solute resulting from penetration into the cell pack. This uptake is expressed as a space value (S), which is defined as the fraction (or percentage) of the volume of the pack that the solute can penetrate. However, uptake into the cell pack involves space both between as well as inside the cells, and therefore correction for the interstitium must be made. With a non-penetrating macromolecule, such as a high molecular weight dextran, the intercellular space (S_{in}) for spores centrifuged at 17,000g for 30 min. was about 10 per cent but needed to be determined in each experiment. After appropriate allowance for this value, the uptake is expressed as a corrected space value (R), which is defined as the fraction (or percentage) of the volume of the cells themselves that the solute can penetrate.

Test of the impermeability hypothesis was made initially with glucose employed in a concentration of 10 mgm./ml. in distilled water at pH 6·8 and 0° C. with a 15-min. exposure period. After allowance for the intercellular space, the corrected mean glucose space (R) was found to be about 40 per cent whether measured isotopically, gravimetrically or by carbon combustion (Table 1). This uptake of glucose was essentially independent of temperature, pH, solute concentration, period of exposure and presence of other solutes or sodium azide and could be completely eluted with water. Thus, the observed uptake of glucose could not be accounted for by surface adsorption, exchange with internal glucose or metabolic removal. Rather, there appeared to be a net diffusional entry into a region occupying 40 per cent of the spore volume.

Table 1. UPTAKE OF GLUCOSE BY DORMANT SPORES

Analytical method	No. of experiments	R (%)		
		Range	Mean	*S.D.*
Gravimetric	8	31–47	40	1·4
Isotopic	4	34–51	40	5·7
Carbon combustion	7	34–47	42	3·9

If so, then other small molecules could be expected to permeate dormant spores to much the same extent. Indeed, a series of representative compounds that included organic acids, amino-acids, sugars and sugar alcohols gave space values approximating that for glucose (Table 2). Two types of compounds provided notable exceptions. Compounds such as adenosine gave variably high space values, and elution was possible only at the isoelectric point, suggesting some adsorptive uptake. Compounds such as ethylene glycol and urea gave constantly high space values (up to 57 per cent) which appeared to be real and possibly associated with lipid solubility. Murrell and Scott[3] have demonstrated that deuterium solution can mix freely with the total water volume of bacterial spores. We are now attempting to confirm, by means of the space technique, this seemingly complete permeation of water into the spore.

Table 2. UPTAKE OF VARIOUS SOLUTES BY DORMANT SPORES

Solute	R	Solute	R
Pyruvate	0·42	Glucose	0·40
Succinate	0·44	Ribose	0·41
Citrate	0·41	Maltose	0·44
DL-Alanine	0·32	Raffinose	0·42
DL-Valine	0·40	Erythritol	0·42
L-Lysine	0·42	Glycerol	0·44
L-Aspartate	0·41	Ethylene glycol	0·53
Adenine	1·10	Propylene glycol	0·53
Adenosine	0·76–1·2	Urea	0·57

Uptake of larger molecules was determined with a graded molecular weight series (62–2,000,000) of polyethylene glycols and dextrans. Space values for these two compounds were comparable and diminished linearly through a hundred-fold increase in molecular weight, suggesting that the surface structures of spores into which exogenous solute penetrates have the equivalent of pores which either vary in size or become progressively smaller with depth. A minimum uncorrected space value of about 10 per cent occurred with dextrans of molecular weight 100,000 or greater; this constant value was concluded to represent the intercellular space.

Concurrent and previous studies[1] on structural differentiation and associated physiological changes have intimated that diffusional uptake is limited to the multilayered thick coat of the spore. Two internal membranes, the cortex and the contiguous inner membrane, appear to be formed at the same time that the core, apparently, of a maturing spore becomes light-refractile and resistant to stains. A mature spore with a fully formed cortex actually takes up stains, as measured with the space technique, and can be seen to absorb stain in its peripheral structure. Furthermore, such a spore can be totally stained after it has been crushed, indicating that the core is not chromophobic but that a barrier shielding it has been broken. Attempts also were made to localize the observed uptake by comparing average R values with direct measurements of spore-coat space. Calculations from measurements on electron micrographs of medial ultra-thin sections indicated that the volume occupied by spore membranes external to the core is approximately 40 per cent of the total spore volume, assuming spores to be ellipsoids of revolution and the spore structure to be of uniform density. This apparent localization of solute permeation in the peripheral membranes of dormant spores is being investigated further.

Detailed reports of these findings will be published elsewhere.

Decontaminating Tissue Cultures infected with Pleuropneumonia-like Organisms

THE contamination of tissue culture cell lines by pleuropneumonia-like organisms has become an increasingly important problem[1–4]. The contamination itself is insidious and cannot be detected ordinarily by gross changes in the appearance of the media macroscopically or microscopically. The tissue culture cells themselves, when observed microscopically, may or may not exhibit slight cytopathology as evidenced by intracytoplasmic granularity. Properly stained preparations may reveal intracytoplasmic particles, presumably the contaminating pleuropneumonia-like organisms[5–7].

At present it is not understood how these organisms gain entrance to cultures, although speculation that they represent *L* forms of bacterial contaminants seems to provide the most likely explanation[4]. Most pleuropneumonia-like organisms are resistant to penicillin but susceptible in varying degrees to streptomycin and certain of the broad-spectrum antibiotics[8,9]. Certain evidence indicates that the presence of high concentrations of antibiotics to which pleuropneumonia-like organisms are sensitive drives these organisms into intracellular residence, and that when the antibiotic concentration drops below a critical level (due to long incubation at 37° C. or extremes of *p*H) the organisms are free to reappear in the supernatant fluids. This cycle of appearance and disappearance of pleuropneumonia-like organisms in tissue culture fluids containing antibiotics must be considered when isolations of organisms are attempted from tissue cultures.

Since routine sampling of tissue culture media components including serum has not as yet revealed pleuropneumonia-like organisms, another explanation for the source of contamination must be considered. The suggestion that cell lines have been contaminated from the tissue of origin is probably not valid since: (1) routine sampling of primary tissue cultures has not revealed these organisms and (2) studies of HeLa cell cultures have not substantiated interpretations favourable to the hypothesis. The widespread prevalence of pleuropneumonia-like organism contamination of HeLa cell cultures and the frequent occurrence of pleuropneumonia-like organisms in the urogenital tract had been regarded as evidence that contamination occurred when the cell line was first isolated. However, routine testing of a number of HeLa sublines in 1953, when HeLa was first generally available, always gave negative results[5]. The techniques used in the attempted isolations at that time were the same as those used recently which resulted in positive isolations[4].

Accordingly, another explanation has been offered, that the pleuropneumonia-like organisms probably represent *L* forms of bacterial contaminants[4]. A complete list of the kinds of environmental trauma that can induce bacteria to revert to *L* forms is lacking. It is known, however, that agents like glycine, raffinose, salts of light metals, carboxymethoxylamine, chloromycetin, cold, X-rays, phage, glycerol and most of all penicillin, can cause this reversion[10]. This list includes a number of reagents that are used routinely in the tissue culture technique. Therefore the hypothesis is proposed that the *L* forms present in tissue cultures were induced by the action of penicillin, and also perhaps by glycine, salts of light metals, and glycerol, on bacteria. This process occurs when breaks in aseptic technique allow for the presence of contaminating bacteria which, under the influence of one of these reagents, revert to the corresponding *L* form.

A method for decontaminating pleuropneumonia-like organism (or *L* form) contaminated tissue cultures has been developed and is based on the differential heat lability of the pleuropneumonia-like organisms and the tissue culture cells. It has been found that if tissue culture cell lines, such as HeLa, *L* cells, *WISH* (a human amnion line), Fernandes amnion, and a human renal line, have been either naturally or artificially contaminated with pleuropneumonia-like organisms and are then held at 41° C. for about 18 hr., they remain negative for pleuropneumonia-like organisms indefinitely. The pleuropneumonia-like organisms are very heat-labile. Some strains are killed at 45° C. for 15 min., others succumb at 45° C. for 30 min.[11]. Tissue culture cells held at 45° C., in general, do not survive, yet when incubated at 41° C. for a long period of time differential survival is achieved—the pleuropneumonia-like organisms are killed and the tissue culture cells survive.

This hyperthermic treatment of cell lines is not without some effect on the cells, and tolerance to 41° C. varies from cell line to cell line, although they all apparently will survive[12]. HeLa at 41° C. has a tendency toward arborization, withdrawal of processes, some rounding and cytoplasmic vacuolization. However, this is by no means fatal to the culture, and once the cells are placed at 37° C. after treatment, recovery is almost always assured. Confirmation of the heat lability of two tissue culture pleuropneumonia-like organism contaminants was obtained when these strains were found to be killed when grown out on agar and then subjected to 41° C. for 18 hr. It is recommended that for optimum simplicity the heat treatment be done in air, since if a water-bath is used it will necessitate complete submersion of the tissue culture vessel in water, with concomitant problems of possible water leakage through the stopper.

Evidence has recently been offered that aureomycin in doses toxic to the tissue culture cells was successful in eliminating contamination by pleuropneumonia-like organisms[13]. This technique entails the use of an antibiotic not normally used in tissue culture, and the material must be added at each media change every 2 or 3 days. Additionally, it is known that there is a great variability in the toxic levels of aureomycin for any particular tissue culture cell line[13]. This would necessitate experimentation with each tissue culture cell line to determine the toxic dose. The hyperthermic technique obviates this disadvantage.

The advantages of the hyperthermic technique are: (1) no new chemical or antibiotic is introduced into the culture; (2) there is assurance that the pleuropneumonia-like organisms are killed, not merely arrested in growth by the bacteriostatic effect of antibiotics[11]; (3) intracellular pleuropneumonia-like organisms are also killed; (4) the method is very simple and easy to carry out.

PATHOLOGY

Cerebellar and Midbrain Lesions in Scrapie

ATAXIA, inco-ordination of movement and to a limited extent disturbances in muscular tonus appear to be the main neurological symptoms in scrapie disease of sheep. Such symptoms suggested cerebellar lesions and indeed lesions have been demonstrated in the cerebellum[1-3], but only occasionally. Recently, an alteration has been made in our technique of taking material from the cerebellum for the routine histological examinations. Dorso-ventral sections have been taken through the middle of the cerebellum, parallel to the long axis of the brain, instead of the usual slice from a sagittal section through the vermis. Examination of such sections from nine brains of sheep affected with natural scrapie showed in each case degeneration and vacuolation of the Purkinje cells in a number of the folia of the paraflocculus (Fig. 1), while occasionally the neurones of the dentate nucleus were also affected. In the midbrains of these animals, in addition to vacuolation of the pigmented cells of the raphe, chromatolysis of the neurones of the red nucleus was a constant finding, while vacuolation was also often present. In the pons the neurones of the nucleus of the abducens nerve were always degenerated and vacuolated, but in the cells of the reticular formation changes were present in seven cases out of nine. In the medulla, lesions were found in the nuclei of the raphe, arcuate and formatio reticularis alba. Lesions of the above nuclei of the medulla have previously been shown to be constantly present in both natural and experimental scrapie[3,4].

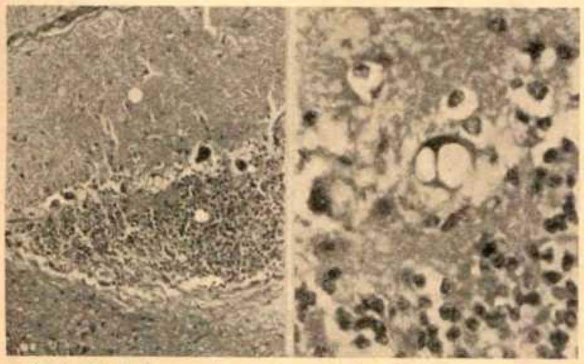

Fig. 1. Left, degeneration and vacuolation of the Purkinje cells (× 90); right, high-power magnification of a vacuolated Purkinje cell (× 360)

In the experimentally induced disease, although the clinical symptoms are identical with those of natural scrapie, lesions in the medulla and pons are not always very obvious[4] and although the distribution of such lesions as there are is similar to that seen in the naturally occurring disease the neurones undergoing degeneration are occasionally so few in number that it is difficult to relate the symptoms to the lesions. In the majority of experimental scrapie cases so far examined the neurones of the red nucleus of the mesencephalon were often affected as also were cells in the medulla and pons, but on occasion no lesions could be found in the midbrain even when 18 consecutive serial sections were examined. Recently, however, transverse sections of the mesencephalon from three such brains have been examined by cutting serial sections along the whole of the red nucleus. A total of 1,000 sections 7μ thick were cut but only every fourth section was examined, and in each of the three midbrains a varying number of the large neurones of the red nucleus was found undergoing either chromatolysis, pyknosis or necrosis. It would seem, therefore, that in all cases of scrapie the neurones of the red nucleus are affected. It is known that in lower mammals including the sheep the red nucleus serves as a centre through which the cerebellum can influence the motor functions of the spinal cord and medulla oblongata[5]. Lesions in the red nucleus and cerebellum will therefore cause lack of co-ordination of muscular activity as well as disturbances in tonus and synergy.

Effect of Injection of a Hepatotoxin directly into the Gall-Bladder of Rabbits

AN inflammatory condition of the bile ducts is generally recognized to be the essential feature of 'facial eczema' liver damage in sheep[1]. This condition has recently been shown to be caused by a toxic principle elaborated by the fungus *Sporidesmium bakeri* Syd., a common species inhabiting many pastures in New Zealand (ref. 2 and Percival, J. C., unpublished work). Guinea pigs and rabbits have also been shown to be susceptible to the disease, liver damage of a generally similar nature having been produced by feeding toxic grass and crude fungal culture, and ether-extracts of these (Clare, N. T., unpublished work), and also by injection of extracts (Worker, N. A., unpublished work).

Recently, in a series of experiments on rabbits, in which the relative effectiveness of various routes of administration was compared, ether extracts of fungus, dispersed in 5 per cent aqueous 'Tween 40', were injected into: (1) the duodenum, proximal to the sphincter of Oddi; (2) the portal vein; (3) the gall-bladder.

Twenty New Zealand white rabbits of mixed sex, weighing 1,000–1,500 gm., were allotted to each group at random. Each rabbit was dosed with the equivalent of 1 litre of fungal culture dispersed in 0·4 ml. 'Tween'. The animals were killed at periods varying from four to seven days. Examination of the morbid anatomy and histology of the livers was carried out by D. C. Dodd, veterinary diagnostic officer of this Station.

From the results summarized in Table 1, it can be seen that after injection of extracts into the duodenum and into the portal vein, the majority of animals in both treatment groups exhibited mild to moderate liver damage, the lesions being similar both macroscopically and histologically to those commonly found after administration of toxic material by mouth (Dodd, D. C., unpublished work). In contrast to these results, however, injection of toxic extract into the gall-bladder produced, in every animal, lesions of the most severe form. The end result of this direct injection procedure was inevitably functional obliteration of the gall-bladder, with very severe generalized

Table 1. GRADINGS OF LIVER LESIONS IN RABBITS AFTER ADMINISTRATION OF FACIAL ECZEMA TOXIN BY DIFFERENT ROUTES
Gradings based on macroscopic and histological examination

Route of administration	Grading			
	Mild	Moderate	Severe	Very severe
(1) Duodenum	7	11	2	0
(2) Portal vein	6	10	4	0
(3) Gall-bladder	0	0	0	20

œdema and fibrosis of the intra- and extra-hepatic biliary systems, together with gross enlargement of the liver and marked discoloration. A most outstanding feature of the results was the completely generalized effects of the treatment throughout all lobes of the liver. Twelve of the twenty animals so treated exhibited clinical icterus, a condition which was not noted in either of the other experimental groups and which in the past has been seldom encountered in rabbits in the course of other studies relating to this disease.

The results of the above studies represent a somewhat perplexing situation. In particular, the completely generalized effect noted throughout the liver of every animal in group 3 is puzzling and is difficult to explain satisfactorily in terms of the accepted facts of liver physiology and function. Expulsion of the toxic dose by way of the common bile duct followed by its subsequent resorption through the intestine would appear to be ruled out as a major contributing factor in view of the finding that injection of equivalent amounts of toxin into the duodenum (treatment 1) or the portal vein (treatment 2) produced damage of very much lesser severity. Similarly, it would appear that absorption of the dose through the venous drainage of the gall-bladder is not a factor of any great significance since cystic venous blood discharges into the portal circulation immediately adjacent to the liver, a situation as represented in treatment 2.

One possible explanation for this effect might be a retrograde movement of toxin from the gall-bladder into the biliary tree. Although it is difficult to visualize a diffusion of toxin against a bile flow which has been shown in this laboratory, in animals of similar size, to be of the order of 6–10 ml. per hr., such a hypothesis would provide an adequate explanation for the extreme severity of the lesions and for the uniform distribution of damaged biliary epithelial tissue throughout the entire substance of the liver.

This hypothesis clearly requires further investigation, not only in view of its general interest, but more particularly because of its possible implications in the pathogenesis of liver damage in facial eczema. If it can be demonstrated that, after concentration and storage in the gall-bladder, materials can re-enter and move freely within the biliary tree, it would suggest that in animals grazing under field conditions the function of the gall-bladder and biliary apparatus may be an important factor in the development of liver lesions. Attempts are being made with the aid of radio-opaque tracers to study gall-bladder function in more detail and to follow more closely the course taken by materials in transit from the gall-bladder to the intestine.

Effects of Dehydration on the Mitochondria of the Mouse Kidney

THE effect of complete withdrawal of water on the animal organism has been studied very little from the point of view of morbid anatomy. The changes observed have been included in the signs of general cell damage such as cloudy swelling, for example.

Modern histochemical techniques[1,2] have made it possible to get information not only about intracellular oxidative mechanisms but also about the physical state of the mitochondria. Employment of the techniques in this way can be referred to as 'mitochondrial assay'[3]. It has been possible to localize cellular damage within a few hours in sites where lesions observable with the classical methods of histology develop only after some days or weeks. By this means it has been shown that swelling of the mitochondria of the kidney is a very early sign of pathological change in a number of conditions, such as magnesium depletion[4], starvation[5], and vitamin D overdosage[6].

The effect of complete dehydration on the mouse kidney has now been studied using histochemical reactions for succinic dehydrogenase and diphosphopyridine nucleotide diaphorase[7]. Mice were killed after 1, 2, 3 and 4 days complete deprivation of water.

With both dehydrogenase and diaphorase methods mitochondrial swelling could be observed after only one day of water deprivation. The intramitochondrial formazan deposits became larger in a limited number of tubular cells, distributed over the whole nephron. During subsequent days mitochondrial swelling increased progressively; in Fig. 1 is shown the reaction for diphosphopyridine nucleotide diaphorase after 4 days of water deprivation. When the animals were allowed to drink water after 4 days dehydration, the mitochondrial changes were rapidly reversed and the picture returned to normal, as shown in Fig. 2.

It is known that the laboratory animals can concentrate their urine to a much greater extent than

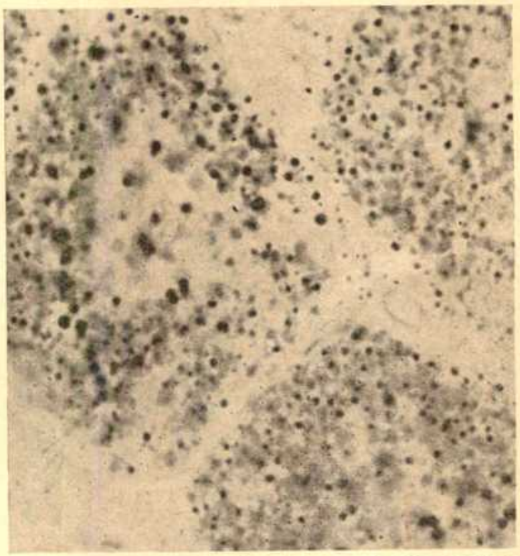

Fig. 1. Reduced diphosphopyridine nucleotide diaphorase reaction of the mouse kidney after four days complete water deprivation (× 1,800)

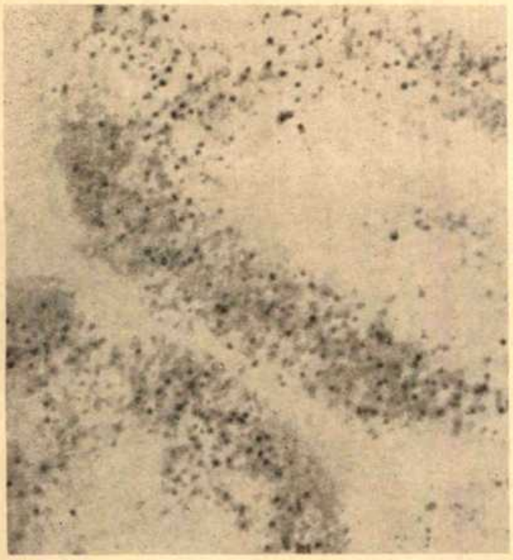

Fig. 2. Same reaction 24 hr. after allowing the dehydrated animal free access to water (× 1,800)

man. It has been believed that this ability to concentrate is a physiological function causing no morphological change in the cells. The results presented here suggest, however, that the high concentration of urine is achieved at the expense of a reversible mitochondrial damage.

A New Approach to Tumour Immunity

ONLY rarely and depending on special conditions has actively acquired immunity been demonstrated for tumours indigenous to and tested within inbred strains of mice[1-3] or rats[4]. For this reason doubts have been expressed as to whether 'tumour immunity' exists independent of isoantigenic differences. Experiments carried out in this laboratory and summarized in Table 1 have utilized inoculation into mice of inbred strains of tumours produced in F_1 hybrid mice derived from the corresponding parent strains. Mice of the parent strain in which the F_1 'hybrid tumour' failed to grow were challenged with a tumour indigenous to and specific for their own strain.

The parent strains were *C57BL*, *C3H*, and *AKR*, from which F_1 hybrids (reciprocal crosses) *C57BL* × *AKR* and *C57BL* × *C3H* were produced. Tumours induced in F_1 hybrids by subcutaneous injection of methylcholanthrene were serially transplanted into F_1 mice of the same origin. Tumour *CAF* in (*C57BL* × *AKR*) F_1 was an infiltrating fibrosarcoma, tumour *CCF* in (*C3H* × *C57BL*) F_1 a moderately well-differentiated mammary carcinoma; both tumours grew in 100 per cent of inoculated homologous F_1 mice. When inoculated into either of the parent strains, these hybrid tumours grew in some animals if sufficiently large numbers of tumour cells were given. The ability of F_1 tumours to grow in parent strains, in spite of immunogenetic differences, has been thoroughly analysed by Klein *et al.*[5]. We have as yet not investigated in detail factors affecting the transplantability of hybrid tumours *CCF* and *CAF* to mice of parent strains. After inoculation of hybrid tumours in increasing doses a percentage of mice of the three parent strains remained free of tumour growth. Upon challenge of *C57BL* mice with sarcoma-89, a fibrosarcoma indigenous to and specific for this strain[6], most of these animals proved resistant to this tumour, as shown in Table 1, while control *C57BL* mice inoculated at the same time succumbed to progressive tumour growth. No such immunity was observed when *C3H* and *AKR* mice, respectively, following inoculation of F_1 hybrid tumours, were afterwards subjected to challenge with tumour indigenous to their strain (transplantable *C3H* mammary carcinoma; *CAM* leukæmia of *AKR* strain): killing tumours developed in 100 per cent of these mice as they did in control mice.

At present no explanation can be offered for the immunizing ability of F_1 hybrid tumours for *C57BL* mice but not for *C3H* and *AKR* mice. Two possibilities may be considered: (1) specific immuno-

Table 1. IMMUNITY TO STRAIN-SPECIFIC TUMOUR OF *C57BL* MICE INOCULATED WITH F_1 TUMOUR

Experiment No.	No. of mice		F_1 tumour inoculation*				No. of mice resistant to F_1 tumour		Sarcoma-89 inoculation*		No. of mice resistant to sarcoma-89	
	M	F	Type†	I	II	III	M	F	I	II	M	F

† For explanation, see text.

genetic mechanisms may be involved, such as presence of a specific antigen common to F_1 hybrid tumour and sarcoma-89. In this connexion, it should be noted that while the *CAF* tumour was derived from a methylcholanthrene-induced sarcoma as was also sarcoma-89, the *CAF* hybrid tumour originated from a mammary carcinoma of a host injected with methylcholanthrene. Study of possible immunizing ability present in normal tissues of F_1 has been initiated by injecting *C57BL* mice with splenic cells of (*C57BL* × *AKR*) F_1 mice prior to inoculation with sarcoma-89. (2) Another possibility is suggested by previous studies in which we found *C57BL* mice to be much more potent antibody producers than *C3H* and *AKR* mice, as judged from levels of antibodies after injection of heterologous red cells[7]. On this basis one might suspect that only *C57BL* mice, but not *AKR* and *C3H* mice, produced sufficient antibody to F_1 hybrid tumours.

This work is now being expanded, with inclusion of additional systems testing immunizing ability of F_1 tumours in other inbred strains in order to elucidate the phenomenon described.

Presence of 3-Methoxy-4-hydroxyphenylglycol and Metanephrine in Phæochromocytoma Tissue

THE ethereal sulphate of 3-methoxy-4-hydroxyphenylglycol, a metabolite of epinephrine and norepinephrine, has recently been demonstrated in the urine of normal individuals and was noted to be markedly increased in the urine of patients having phæochromocytoma[1]. The free compound has not been previously demonstrated and the possibility that conjugated (nor)metanephrine gives rise to this compound could not be ruled out. We have now been able to demonstrate the presence of free 3-methoxy-4-hydroxyphenylglycol in phæochromocytoma tissue from four different patients, as well as metanephrine in three of these tumours.

About 5 gm. of phæochromocytoma tissue was homogenized with 2 vol. of 0·5 *M* acetate buffer at *p*H 3, saturated with sodium chloride and extracted into 10 vol. of ethyl acetate. The ethyl acetate extract was then washed with salt-saturated acetate buffer at *p*H 7 and evaporated to dryness *in vacuo*. The residue was taken up in 10 ml. acetone, transferred to a 15-ml. centrifuge tube, and the solvent evaporated in a current of nitrogen until the volume was about 4 c.c. After centrifugation, 0·5 ml. of the supernatant fluid was applied to Whatman No. 1 paper and subjected to two-dimensional chromatography using *iso*propanol/5 per cent ammonia (8 : 2) and *n*-butanol/acetic acid/water (8 : 8 : 2) as the solvent systems. A spot was present having the same R_F and colour reactions as authentic 3-methoxy-4-hydroxyphenylglycol[1]. Addition of the authentic substance to the chromatogram increased the intensity of this spot. From the intensity of the colour of the spot, it was estimated that 5–10 μgm. of the glycol per gm. of tissue was present in the tumours.

Another spot, metanephrine[2], was identified in a similar manner and was shown to be different from normetanephrine by separation during chromatography. This substance was demonstrated in three of the four tumours.

The demonstration of unconjugated 3-methoxy-4-hydroxyphenylglycol of biological origin has not been previously reported. This supports the pathway for formation of the sulphate of this metabolite from the free compound, rather than from (nor)metanephrine sulphate. Although normetanephrine has been reported in phæochromocytoma[3], this is the first demonstration of the presence of metanephrine in these tumours.

We wish to thank Dr. Richard Crout, National Heart Institute, and Dr. Arthur Grollmann, jun., Johns Hopkins Hospital, Department of Medicine, for making available samples of phæochromocytoma tissue.

A Soluble Protective Antigen of *Trypanosoma brucei*

Trypanosoma brucei in quantities sufficient for antigenic analysis was obtained by harvesting the blood of rats on the third day of infection by the protozoon, when the fulminating parasitæmia is at its height. The trypanosomes were separated from the blood by centrifugation and the resulting mash was preserved by freeze drying. Several batches made in this way were pooled.

Rabbits inoculated with this material produced not only agglutinins for live trypanosomes but also antibodies precipitating with rat serum. These precipitins, a response to traces of serum proteins not removed during the separation of the trypanosomes from the blood, were removed by absorption with normal rat serum. The absorbed antiserum, no longer reacting with normal rat serum, nevertheless precipitated with some component in the serum of infected rats, from which the trypanosomes had been removed by filtration ; suggesting that infected rat serum contained an antigen peculiar to the infected state. This antigen was designated the 'exoantigen' of *T. brucei*.

Antisera to the exoantigen, free of antibodies to normal rat serum, were prepared by inoculating normal rats with trypanosome-free infected rat serum. These antisera not only precipitated exoantigens, but also agglutinated living trypanosomes *in vitro*, suggesting strongly that the exoantigens were liberated from trypanosomes and were not of rat origin. About a million living trypanosomes, which had been washed as thoroughly as possible, were injected into rabbits and in two or three weeks the protozoa proliferated sufficiently to produce the typical chronic infection, and to induce antibodies, which agglutinated trypanosomes and precipitated the exoantigen present in infected rat serum. It is evident from quantitative considerations that the precipitins were not induced by an abnormal rat metabolite carried on the original inoculum but by antigens liberated from the multiplying trypanosomes. First, the amount of rat serum proteins contaminating the inoculum was insufficient to stimulate antibodies to normal serum proteins and therefore to the certainly much smaller amounts of exoantigen present. Secondly, the million trypanosomes injected could not have been carrying an antigenically effective amount of an abnormal rat metabolite because grams of wet weight of dead trypanosomes from the rat are needed to induce a similar antibody response in rabbits.

The *in vitro* agglutination of living trypanosomes both by rabbit antisera to living trypanosomes and by rabbit or rat antisera to exoantigen was specifically inhibited by exoantigen. In gel-diffusion precipitin systems, the exoantigen formed a continuous line when opposed to adjacent reservoirs of each of the two kinds of antisera. Thus, antibody of the same specificity was induced whether the provoking antigen was living and multiplying trypanosomes or exoantigens in infected rat serum free of trypanosomes, leaving no doubt that the exoantigen was liberated from the trypanosomes and was not an abnormal rat metabolite. In an immuno-electrophoretic analysis of infected rat serum exoantigen appears as a slow-moving component, moving even more slowly than the serum γ-globulin.

Certain biological effects of free exoantigen indicate that it is concerned with the process of infection. When trypanosomes are collected from infected animals their viability *in vitro* largely depends on the type of medium in which they are contained. Washed suspensions of living trypanosomes were re-suspended in (1) Alsever's solution, (2) Alsever's solution plus normal rat serum, and (3) Alsever's solution plus infected rat serum containing exoantigen; they were injected into mice after standing at room temperature for 1–2 hr. Suspensions in Alsever's solution alone were usually non-infective. The time to death after injection of serum-treated preparations depended not only on the dose of trypanosomes, but also on the nature and amount of the added serum. Mice receiving trypanosomes and infected rat serum invariably died first, and the time to death was directly proportional to the concentration of exoantigen added. Mice receiving trypanosomes and normal rat serum always died later, if at all. Moreover, when suspensions of trypanosomes in normal and infected rat serum were held for varying periods on the bench, the older suspensions were the less infective, although the suspensions containing exoantigen remained infective for longer periods than those with normal rat serum. Since exoantigen appears to be relatively stable, it is unlikely to have been acting as an aggressin the potency of which was declining during the period on the bench; so that the increased infectivity of suspensions containing exoantigen appears mainly to be due to the more efficient preservation of the viability of the trypanosomes *in vitro*.

Nevertheless, though the exoantigen does not in these circumstances behave as a soluble aggressin, it has immunogenic properties. Repeated injection of exoantigen into mice and rats actively immunizes the animals against infection by live trypanosomes. Presumably, therefore, antibody to exoantigen is protective.

In conclusion, the exoantigen of *T. brucei* which occurs in the serum of infected rats plays an essential part in infection and is a means by which laboratory animals can be immunized against *T. brucei* by syringe inoculation. Its immunogenic efficiency against the infection transmitted by the tsetse fly—an experimental system closer to the natural disease—is under investigation.

Runt Disease and Tolerance in Rabbits

The production of immunological tolerance, that is, specific inhibition of the immune response in adult life by contact with antigen at an early age, was first described by Billingham, Brent and Medawar[1] and Hašek[2]. By this means, animals of different strains or breeds can be made to accept skin homografts from each other in adult life, provided they have been injected in the fœtal or early neonatal period with cells taken from their future skin donors.

The time in early life (adaptive period) during which the animal reacts to the administration of foreign cells by becoming tolerant varies considerably from species to species. In rats[3] it ends some days after birth, in mice at birth[4], but in rabbits incomplete evidence suggests it probably ends some time before the end of intra-uterine existence[5]. Moreover, when the cells used to induce this tolerance are adult and capable of forming antibody, a considerable proportion of the recipients may develop runt disease, characterized by chronic wasting and premature death[4].

Recently, as part of a study of graft-against-host reactions in the rabbit, it became necessary to produce runts in this species. As this has not been described before, and as detailed information on the adaptive period in rabbits was incidentally obtained, the results may be of interest to others.

Homologous spleen cells from adult female chinchilla rabbits were injected into newborn or fœtal rabbits. The donor animal was anæsthetized and splenectomy performed. The spleen was finely chopped in heparinized saline, and then suspended by gently drawing up and down through a wide-bore cannula. After filtration through nylon bolting cloth of 90-μ porosity, a cell count was made and a suitable quantity of the spleen suspension injected into the recipient. Newborn rabbits were injected intravenously within 1–4 hr. of birth. To inject fœtuses, a laparotomy was performed on a pregnant rabbit and the uterus delivered through the wound. The head and back of each fœtus were identified, and then spleen suspension injected into the peritoneal cavity of each. The uterus was returned to the abdomen and the wound sutured. When possible, the recipients of spleen cell suspension were challenged at 8 weeks with skin grafts from the spleen donor, skin homografts from another unrelated donor and autografts. These were full-thickness grafts 2 cm. in diameter sutured into prepared beds upon the ears[6].

Table 1. Incidence of Runt Disease and Survival Time of Skin Homografts in Rabbits given Homologous Spleen Cells in Fœtal Life or at Birth

Group	No. of rabbits injected	Route of injection	Age at time of injection	No. of dead at birth	No. of runts	Survival times of skin grafts from spleen donors (days)
25 × 10^6 cells injected						
I	8	Intravenously	1–4 hr. after birth	0	0	6, 6, 6, 6, 7, 7, 8, 9
II	10	Intraperitoneally	28th day in utero	1	0	6, 6, 6, 7, 7, 8, 8, 8, 9
III	9	,,	26th day in utero	1	0	6, 6, 7, 7, 7, 8, 8, 9
IV	10	,,	24th day in utero	1	0	9, 9, 9, 9, 10, 10, 11, 11, 12
V	12	,,	22nd day in utero	2	1	7, 8, 9, 12, 18*, 20, 24, 28, 34, 180

50 × 10^6 cells injected						
VII	18	,,	22nd day in utero	7	5	7, 8, 16*, 24, 38, 180
VIII	21	,,	20th day in utero	9	8	14*, 68, 90, 180, 180

* Runts with viable skin grafts at time of death of host.

It can be seen from Table 1 that the adaptive period in the rabbit ends about the twenty-second day of gestation (normally pregnancy lasts 31 days). Giving rabbits 25 (× 10^6) spleen cells intravenously immediately after birth or intraperitoneally any time after the twenty-second day of fœtal life failed to produce immunological tolerance or runt disease.

Indeed, in fœtuses injected at the twenty-sixth day of pregnancy or later, skin homografts from the spleen donor were rejected more rapidly than corresponding homografts from unrelated rabbits, suggesting that immunity had resulted and that these pieces of skin were behaving as 'second-set' grafts[7]. In the 25 animals from groups I, II and III that were skin grafted, the mean survival times for the 'spleen donor' and 'unrelated' skin transplants were found to be $7\cdot12 \pm 1\cdot05$ and $10\cdot04 \pm 1\cdot21$ days, respectively, a difference which is significant ($P < 0\cdot01$).

After the critical twenty-second day there seems to be a brief 'neutral' period in which foreign cells are unable to induce either tolerance or immunity. Thus, in animals exposed to spleen cells at the twenty-fourth day of fœtal life (Group IV), there is no significant difference ($P > 0\cdot10$) between the survival times of skin homografts from the spleen donors and those of grafts from unrelated donors.

Of the 12 fœtal rabbits injected at 22 days (Group V), 6 became tolerant and showed definite prolongation of survival of skin homografts from the spleen donor, but not from the unrelated donor. Tolerance was not complete, and only one animal has an intact graft at the time of reporting (180 days). In another of the animals runt disease was encountered, as was only to be expected after the introduction of adult immunologically competent cells into an immature animal, and one of the two animals dead at birth showed the lymphoid atrophy usually associated with this syndrome.

In Group VI (injected at 20 days) all the surviving animals showed tolerance of varying degrees to spleen donor skin grafts. Runt disease was more common than in Group V and three of the five animals born dead showed evidence of the same process.

Increasing the dose of spleen suspension injected into 22- and 20-day old fœtuses to 50 (× 10^6) nucleated cells greatly raised the incidence of runt disease and the number of rabbits born dead (Groups VII and VIII). 9 of the 16 animals dead at birth showed lymphoid atrophy. The degree of tolerance was greater and runt disease more frequent and severe among those treated at the twentieth day of fœtal life than with those treated at the twenty-second day. The animals which developed a high degree of tolerance without showing runt disease clinically gained weight more slowly than their less tolerant litter mates and showed some lymphoid damage.

Some of the rabbits in which runt disease was induced developed an immune hæmolytic anæmia. Investigations into this phenomenon and the histological changes found in association with the runting syndrome will be reported in detail elsewhere.

My thanks are due to Miss J. Rendall for technical assistance. This work was supported by a grant from the Medical Research Council.

VIROLOGY

Electron-dense Crystallites in Nuclei of Human Amnion Cells infected with Measles Virus

Measles virus antigen has been specifically identified in the nuclei of infected cells by means of the fluorescent antibody technique; and the development and spread of virus antigen in amnion and other human cells have been correlated with observations made in a concurrent study of fine structure[1]. During a continuation of the latter investigation we have found that crystallites made up of ordered arrays of electron-dense particles occur within nuclei of infected human amnion cells, and have also observed extracellular particles that can be interpreted as mature virus.

Twenty-one days after the cells were infected with the Edmonston strain of measles virus, they were fixed in osmium tetroxide, and ultra-thin sections were prepared for electron microscopy. Sections were mounted on 200-mesh grids and floated for 15 min. on a saturated solution of uranyl acetate to enhance contrast.

Many of the cells contained intracytoplasmic inclusion bodies that have been described in detail[1]. In addition, the nuclei of a few cells contained

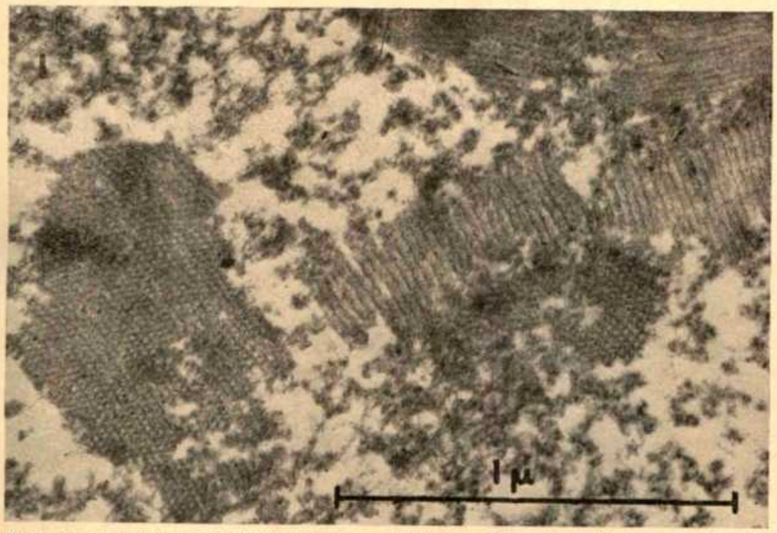

Fig. 1. Several orientations of intranuclear crystallites in a thin section of human amnion cell 21 days after infection with measles virus

crystalline arrays (Fig. 1). Crystalline arrays were not seen in uninfected amnion cells. It is reasonable to suppose that the arrays are associated in some way with virus multiplication. Three crystallographic directions can be identified in the crystallite at the left of Fig. 1, suggesting that a (111) plane is being visualized. The observed spacings along the three directions, in conjunction with the angles enclosed (70°, 70°, 40°), can be interpreted in terms of a unit cell with sides 120 Å. × 120 Å. × 211 Å. Other orientations are displayed by the crystallites at the right of Fig. 1, the spacings of which also are in agreement with the above interpretation.

It is unlikely that the crystallites consist of mature measles virus particles. Many of the cells containing crystalline arrays, or characteristic cytoplasmic inclusion bodies[1], or both, show particles on or outside the cell wall that might be interpreted as mature virus because of their morphology and size (Fig. 2). They exhibit double membranes, separated by 50 Å. ; display an internal granular structure ; and have an approximate diameter of 1200 Å. Benyesh *et al.*[2] have reported that the diameter of mature measles virus is approximately 1400 Å. Many of the bodies are 5- or 6-sided in outline, suggesting a polyhedral shape (Figs. 2 and 3).

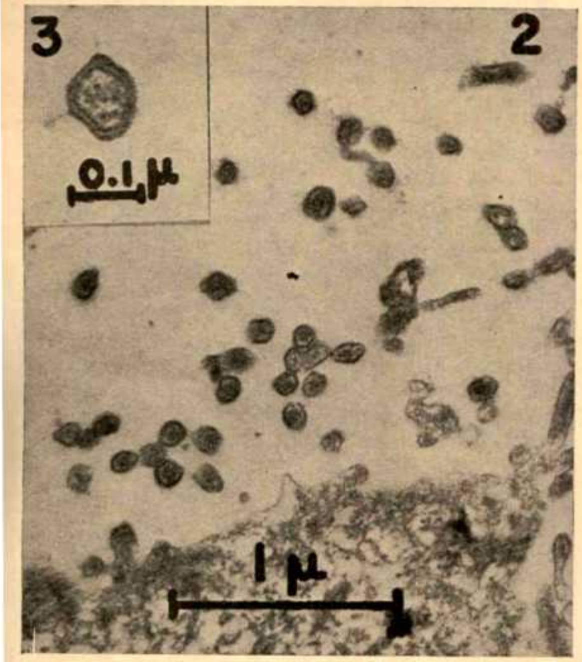

Fig. 2. Virus-like particles outside human amnion cell, showing internal structure and external membrane

Fig. 3. Higher magnification of a particle showing double membrane and suggesting polyhedral shape

Intranuclear crystallites have been observed in electron micrographs of animal cells infected with insect viruses and several mammalian viruses, including adenovirus[3] and herpes virus[4]. In some of the former and both the latter infections, the crystals appeared to be made up of the virus particles themselves. In addition, one type of crystal found in a type 5 adenovirus infection of HeLa cells was shown to be protein[4]. Morgan *et al.*[4] have discussed conditions that may favour the development of intracellular crystals in cells infected with virus, and speculate that the time-rate of virus assembly per unit volume may be the chief factor determining whether an ordered array will form.

Two mature animal viruses having polyhedral shapes have been demonstrated in electron micrographs. *Tipula* iridescent virus is 6-sided in cross-section and is icosahedral[5]. Adenovirus type 5 is also an icosahedron[6]. Three-dimensional studies are needed to determine which polyhedral shape might be assumed by mature measles virus.

This investigation was carried out under the sponsorship of the Commission on Viral Infections, Armed Forces Epidemiological Board, and was supported in part by the Office of the Surgeon General, Department of the Army, and in part by Grant *E*-2418, National Institute of Allergy and Infectious Diseases, National Institutes of Health.

SOIL SCIENCE

Removal of Fixed Ammonium from Clay Minerals by Cation Exchange Resins

Ammonium in clay minerals that is not replaceable by K^+ has been defined as fixed NH_4^+. This fixed NH_4^+ is replaceable to some extent by Na^+ and H^+, but the amount that can be replaced depends upon the extraction method used. Recent work[1,2] has shown that small amounts of K^+ or NH_4^+ in the extracting solution block the replacement of fixed NH_4^+. Thus, the efficiency of an equilibrium extraction of fixed NH_4^+ is decreased by the accumulation of displaced NH_4^+ in the extracting solution[2]. If a clay mineral containing fixed NH_4^+ were equilibrated with a cation exchange resin instead of a soluble salt, there would be less soluble K^+ or NH_4^+ in the system. A comparison of these extraction methods was made, therefore, to determine if there was also less blocking and thus more fixed NH_4^+ removed in a resin extraction.

Samples of Montana vermiculite (0·2 gm.), Wyoming bentonite (0·3 gm.) and Goose Lake Grundite (illite, 0·5 gm.) that had been NH_4^+-saturated and dried at 110°, 350° and 110° C., respectively, were equilibrated with Na^+-, K^+- and H^+-saturated samples of 'Amberlite *IR*-120' in 20 ml. of distilled water. In each case $>$ 32 mesh resin material with an exchange capacity of 4·32 m.equiv. per gm. and a clay mineral : resin ratio of 1 : 20 (oven dry-weight basis) were used. Samples of the dried, NH_4^+-saturated clay minerals (0·2 gm. vermiculite, 0·3 gm. bentonite and 0·5 gm. illite) were also equilibrated with 20 ml. of 1 *N* sodium chloride and with 20 ml. of 1 *N* potassium chloride. The various systems were equilibrated at room temperature by shaking for periods of 2–8 days. The mixtures were then filtered, the residues were leached with 350 ml. of 1 *N* potassium chloride, and the NH_4^+ in the leachates was determined by distillation with potassium hydroxide. Before ammonium saturation, the illite was treated with a solution of sodium chloride and $NaB(C_6H_5)_4$ in order to remove K^+ and increase the NH_4^+ fixing capacity[3]. Illite samples that were not NH_4^+ saturated were included in each experiment, and the results obtained with the NH_4^+-saturated illite were corrected for nitrogen arising from that originally present in this material.

Table 1 gives the total NH_4^+ contents of the minerals (Kjeldahl analysis), their exchangeable NH_4^+ contents as determined by distilling 1-gm. samples with 400 ml. of 1 *N* potassium hydroxide, and the amounts of NH_4^+ removed by the resin and soluble salt extractions. In these extractions enough replacing cation was used to remove at least 80·6, 49·5 and 25·1 m.equiv. of NH_4^+ per 100 gm. from the vermiculite, bentonite and illite samples, respectively, if the distribution coefficient for the exchange of cations was 1.

Table 1. Amounts of NH_4^+ removed from NH_4^+-saturated Clay Minerals by Various Treatments (m.equiv. per 100 gm.)*

Treatment	Ammonium vermiculite	Ammonium bentonite	Ammonium illite
Kjeldahl digestion	81·4	50·4	25·3
Hydrogen resin	80·5	36·7	23·9
Sodium resin	80·5	36·3	23·2
Sodium chloride	66·5	33·0	22·4
Potassium resin	10·7	9·0	22·7
Potassium chloride	8·1	5·7	22·1
Potassium hydroxide distillation	2·8	24·6	22·6

* Mean of two or more determinations. The illite values are corrected for the NH_4^+ removed from similarly treated illite samples that were not NH_4^+-saturated.

Comparison of the results obtained by the resin and soluble salt extractions using the same replacing cation shows that although the resin method of extraction was the more effective with all three minerals, it was not markedly so except in the Na^+ treatment of vermiculite. When the NH_4^+ vermiculite was equilibrated with Na^+ (or H^+) resin essentially all of the NH_4^+ was removed, whereas only 76 per cent of the fixed NH_4^+ (that is, NH_4^+ not removed by distillation with potassium hydroxide) was removed by the sodium chloride treatment. It seems safe to assume that with this mineral the efficiency of the resin technique was due to a decrease in the blocking effect of the replaced NH_4^+, which limited extraction by the sodium chloride technique, since other experiments (to be reported later) indicate that it was not due to a selective adsorption of NH_4^+ by the resin or to a contact effect of the resin.

The influence of the resin on the removal of fixed NH_4^+ from illite and bentonite was very small, and essentially the same, whether Na^+ or K^+ was used. This suggests that with these minerals the effect of the resin was not due to a decrease in the blocking effect of displaced NH_4^+. More likely it was due to grinding of clay particles by the resin during the prolonged shaking period. This would also explain the observation that potassium resin extracted more NH_4^+ from vermiculite than did potassium chloride. In the vermiculite–resin extractions a distinct decrease in the size of the clay particles was observed.

The results in Table 1 show that the different treatments with K^+ (potassium hydroxide, potassium chloride, potassium resin) did not remove the same amount of NH_4^+ from the clay minerals. To define fixed ammonium, it is necessary, therefore, to specify the method of determination even when K^+ is used as the replacing cation. In the present work NH_4^+ that was not liberated as ammonia by distillation with potassium hydroxide was arbitrarily considered as being fixed.

Previous experiments with vermiculite have shown that the blocking effect of NH_4^+ or K^+ can be reduced by increasing the acidity of the extracting solution[2]. In the case of bentonite and illite, however, hydrogen resin was no more effective than sodium resin (Table 1). Also, instead of the increase observed with vermiculite, there was a decrease in the amount of NH_4^+ removed when the bentonite and illite samples were extracted with potassium chloride instead of potassium hydroxide. These results suggest that factors not encountered with vermiculite are involved in the fixation and release of NH_4^+ in bentonite and illite.

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, March 14

University of London (at the Postgraduate Medical School of London, Ducane Road, London, W.12), at 4 p.m.—Prof. E. Zaimis: "Neurochemical Pharmacology".*

Institution of Electrical Engineers, London Graduate and Student Section (at Savoy Place, London, W.C.2), at 6 p.m.—Informal Meeting on "Should Engineers be encouraged to take up Administrative Positions early in their Careers?".

Tuesday, March 15

University of London (at Queen Mary College, Mile End Road, London, E.1), at 1.30 p.m.—Prof. C. D. Darlington, F.R.S.: "Heredity and Human Society".*

British Computer Society, London Branch (at the Northampton College of Advanced Technology, St. John Street, London, E.C.1), at 2.30 p.m.—Mr. N. Doveton: "Axis Transformation using Analogue Equipment".

University of London (at University College Hospital Medical School, University Street, London, W.C.1), at 4.30 p.m.—Prof. M. Maizels: "Salt and Water Balance in Cells".*

Royal Society of Arts, Commonwealth Section (at John Adam Street, Adelphi, London, W.C.2), at 5.15 p.m.—Sir Alan Burns: "Recent Developments in Fiji".

Institution of Electrical Engineers, Measurement and Control Section (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. I. C. Hutcheon and Mr. D. Summers: "Fast-Response Transistor Chopper-Type Amplifier with Low Carrier Frequency".

Royal Aeronautical Society (at 4 Hamilton Place, London, W.1), at 7 p.m.—Prof. H. B. Squire, F.R.S.: "Some Problems of Separated and Vortex Flow".

Tuesday, March 15—Thursday, March 17

Oil and Colour Chemists' Association (in the Royal Horticultural Society's New Hall, Westminster, London, S.W.1)—Twelfth Technical Exhibition

Wednesday, March 16

Royal Society of Arts (at John Adam Street, London, W.C.2), at 2.30 p.m.—Dr. D. Roy Davies: "Induced Mutation in Crop Plants—Prospects and Prospectives" (Fernhurst Lecture).

Geological Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr. D. V. Ager: "The Epifauna of a Devonian Spiriferid"; Dr. G. Kelling: "The Stratigraphy and Structure of the Ordovician Rocks of the Rhinns of Galloway".

Royal Meteorological Society (at 49 Cromwell Road, London, S.W.7), at 5 p.m.—Mr. D. W. Martin and Mr. A. W. Brewer: "A Synoptic Study of Day-to-Day Changes of Ozone over the British Isles"; Mr. E. B. Kraus: "Synoptic and Dynamic Aspects of Climatic Change".

Royal Statistical Society (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.15 p.m.—Mr. P. A. Stone: "Economics of Building Designs".

Institution of Electrical Engineers, Supply Section (at Savoy Place, London, W.C.2), at 5.30 p.m.—Dr. D. H. Grindell: "An Electrostatic Dust Monitor".

Society of Chemical Industry, Corrosion Group (at 14 Belgrave Square, London, S.W.1), at 6 p.m.—Miss D. M. Brasher: "The Mechanism of Inhibition in Neutral Aqueous Solutions".

Society of Chemical Industry, London Section (joint meeting with the London Section of the Royal Institute of Chemistry, at University College, Gower Street, London, W.C.1), at 6.30 p.m.—Prof. F. D. Richardson: "High Temperature Reactions Involving Condensed Phases".

Society for Psychical Research (at Kensington Town Hall, Kensington High Street, London, W.8), at 7 p.m.—Mr. H. Norman Hunt will reproduce recordings from Spiritualist Mediums.

Society of Instrument Technology (at Manson House, 26 Portland Place, London, W.1), at 7 p.m.—Mr. A. H. Doveton and Mr. K. C. W. Pedder: "The Simulation of a Large Chemical Plant on an Electronic Analogue Computer".

Pharmaceutical Society of Great Britain (at 17 Bloomsbury Square, London, W.C.1), at 7.30 p.m.—Dr. A. L. Glenn: "Hydrogen Ions and the Pharmacist".

Thursday, March 17

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Mr. A. R. Peacocke and Mr. B. N. Preston: "The Action of γ-Rays on Sodium Deoxyribonucleate in Solution. II Degradation. III: Denaturation"; Mr. J. Seed: "Inhibition of Nucleic Acid Synthesis Caused by X-irradiation of the Nucleolus".

Linnean Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr. V. H. Heywood: "Progress in the *Flora Europaea* Project"; Mr. Eric M. Marsden-Jones: "The Life Cycle of *Adleria kollari* Hartig (Cynipidae)".

London Mathematical Society (at the Royal Astronomical Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr. P. J. Higgins: "Two Methods in Combinational Analysis".

Institute of Physics, London and Home Counties Branch (at 47 Belgrave Square, London, S.W.1), at 6 p.m.—Prof. F. P. Bowden, C.B.E., F.R.S.: "The Friction and Deformation of Solids at Very High Speed".

Royal Aeronautical Society (at the Institution of Mechanical Engineers, 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Mr. M. B. Morgan: "Supersonic Aircraft—Promise and Problems.".

Society of Chemical Industry, Road and Building Materials Group (at 14 Belgrave Square, London, S.W.1), at 6 p.m.—Mr. P. H. Robin: "Floors Old and New".

Royal Society of Tropical Medicine and Hygiene (at the Royal Army Medical College, Millbank, London, S.W.1), at 7.30 p.m.—Laboratory Meeting. Chairman Sir William MacArthur, K.C.B., D.S.O., M.D., F.R.C.P.

British Institute of Radiology, incorporated with the Rontgen Society (at 32 Welbeck Street, London, W.1), at 8 p.m.—Meeting on "The Reduction of Radiation Hazards in the Therapeutic Use of Small Multiple Radioactive Sources".

Friday, March 18

British Psychological Society, Occupational Psychology Section (in the Department of Psychology, Birkbeck College, Malet Street, London, W.C.1), at 1 p.m.—Dr. Marie Jahoda: "Some Remarks on the Study of Technological Education".

University of London (at the Postgraduate Medical School of London, Ducane Road, London, W.12), at 4 p.m.—Dr. J. A. Fraser Roberts: "Medical Genetics".*

Royal Society of Medicine, Epidemiology and Preventive Medicine Section (at 1 Wimpole Street, London, W.1), at 5.30 p.m.—Dr. W. R. S. Doll and Dr. W. M. Court Brown: "Studies on the Possible Effects of Low Doses of Radiation".

Institution of Electrical Engineers, London Graduate and Student Section (joint meeting with the Graduate and Student Section of the Institutions of Civil and Mechanical Engineers, at the Institution of Mechanical Engineers, Birdcage Walk, London, S.W.1), at 6.30 p.m.—Address by Sir George Edwards, C.B.E.

Society for Analytical Chemistry (joint meeting with the Fine Chemical Group of the Society of Chemical Industry, at the School of Pharmacy, Brunswick Square, London, W.C.1), at 6.30 p.m.—Meeting on "Techniques of Automatic Analysis". Mr. R. M. Pearson: "Automatic Analysis in the Chemical Industry"; Dr. I. D. P. Wootton: "Automation in Clinical Biochemistry".

Antiquarian Horological Society (at the Science Museum, South Kensington, London, S.W.7), at 7 p.m.—Discussion on the work of the Ellicotts.

British Institute of Radiology, incorporated with the Rontgen Society (at 32 Welbeck Street, London, W.1), at 8 p.m.—Meeting on "Tritium Counting".

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Prof. R. V. Jones: "Infra-red Radiation".

Saturday, March 19

Nutrition Society (at the Medical College of St. Bartholomew's Hospital, Charterhouse Square, London, E.C.1), at 9.45 a.m.—Symposium on "Nutrition and the Elderly".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Senior Lecturer in Hydro- and Aero-dynamics; and a Senior Lecturer in Physics—The Registrar, College of Advanced Technology, Gosta Green, Birmingham 4 (March 19).

Assistant Lecturer in the Department of Mathematics—The Registrar, Queen Mary College (University of London), Mile End Road, London, E.1 (March 22).

Lecturer in Applied Mathematics—Joint Clerk to the University Court, Queen's College (University of St. Andrews), Dundee (March 26).

Lecturer (with medical or scientific qualifications) in Physiology—Joint Clerk to the University Court, Queen's College (University of St. Andrews), Dundee (March 26)

Research Fellows (Ph.D. standard, with a special aptitude for research in high or low energy nuclear physics) in Experimental or Theoretical Nuclear Physics—The Registrar, The University, Liverpool (March 26).

Leverhulme Research Fellow (graduate in medicine or science)—The Secretary, St. Mary's Hospital Medical School, Paddington, London, W.2 (March 28).

Research Fellow (with research experience in biochemistry or chemistry, and an interest in the physico-chemical aspects of biochemistry) in the Department of Physical Biochemistry, John Curtin School of Medical Research, Australian National University—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (March 30).

Assistant Experimental Officer (preferably woman aged at least 22, with B.Sc. pass degree, with bacteriology as principal or subsidiary subject, or equivalent) at Torry Research Station, D.S.I.R., Aberdeen, to work on the maintenance of type cultures for the National Collection of Industrial Bacteria—The Ministry of Labour, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting Ref. G.68/0A (March 31).

Assistant Lecturer in Philosophy, tenable in either the Department of Philosophy, or in the Department of Political and Moral Philosophy—The Registrar, University College of North Staffordshire, Keele, Staffs (March 31).

Chair of Physics at University College, Ibadan, Nigeria—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (March 31).

Demonstrators (2) (graduates) in Agriculture, for duties on the University farms—The Registrar, The University, Leeds 2 (March 31).

Foulerton Gift Research Fellow (British nationality) for original research in Medicine—The Assistant Secretary, The Royal Society, Burlington House, Piccadilly, London, W.1 (March 31).

Junior Lecturer in Botany—The Registrar, Trinity College, Dublin (March 31).

Lecturer or Assistant Lecturer in Mechanical Engineering—The Registrar, Queen Mary College (University of London), Mile End Road, London, E.1 (March 31).

Lecturer or Demonstrator in Agricultural Biochemistry—The Registrar, King's College (University of Durham), Newcastle upon Tyne 1 (March 31).

Research Fellow in the Biophysics Laboratory, Department of Physics, for work largely concerned with the electric properties of plant membranes and tissues and the relation of these to plant development—The Registrar, University of Tasmania, Box 252O, G.P.O., Hobart, Tasmania (March 31).

Senior Lecturer or Lecturer in Mathematics at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (March 31).

White's Professor of Moral Philosophy—The Registrar, University Registry, Oxford (March 31).

Research Worker in Psychopharmacology for work concerned with the effects of psychotropic drugs on psychological and physiological functions, and will involve studies on normal subjects and psychiatric patients—Dr. H. O. Schild, Department of Pharmacology, University College, Gower Street, London, W.C.1 (April 2).

Chair of Biochemistry—The Registrar, The University, Leicester (April 8).

Lecturer in Social Anthropology; and a Lecturer in Agricultural Chemistry—The Secretary of University Court, The University, Glasgow (April 11).

Lecturer in Chemistry in the Department of Chemistry and Chemical Engineering, University of Natal, Durban—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (South Africa and London, April 15).

Lecturer or Assistant Lecturer in Zoology at the University of Malaya (Singapore Division)—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (April 15).

Lecturer/Senior Lecturer (qualified in grassland management) in Animal Husbandry at the University of Sydney Animal Husbandry Farms, Camden, New South Wales—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, April 15).

Lecturer (with research interests in either branch) in Inorganic and/or Physical Chemistry; a Lecturer in Mathematics; and a Lecturer in Moral Philosophy in St. Salvator's College—Joint Clerk to the University Court, College Gate, St. Andrews (April 16).

Assistant Lecturer (with special qualifications in the genetics of micro-organisms) in the Sub-Department of Genetics—The Registrar, The University, Liverpool, quoting Ref. CV/T (April 19).

Research Fellow in Pure Science; a Research Assistant (preferably with a special interest in educational psychology and/or general experimental psychology) in Psychology; and a Graduate Assistant in Zoology, with special responsibility for the Departmental Museum—The Secretary, The University, 38 North Bailey, Durham (April 23).

Senior Lecturer (with a postgraduate degree in either geography or geology from a British university or the equivalent, and teaching experience at university level) in Geography and Geology at the University of Hong Kong—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Hong Kong and London, April 30).

English Electric Research Fellow in Aeronautics, for postgraduate research into the problems of vibration or stability and control of aircraft—The Warden, The College of Aeronautics, Cranfield, Bletchley, Bucks (May 1).

Professor of Engineering Science—The Registrar, University Registry, Oxford (May 5).

Biochemist (B.Sc. or preferably Ph.D., with experience in bacteriology)—The Secretary, Wright Fleming Institute, St. Mary's Hospital Medical School, Paddington, London, W.2.

Biochemist, Senior grade, to take charge at East Riding Group Laboratory—The Secretary, Westwood Hospital, Beverley, East Yorkshire.

Experimental Officers/Assistant Experimental Officers (with G.C.E. "A" level in chemistry and another science or mathematics subject or equivalent, but if over 22, a pass degree, H.N.C. in chemistry or equivalent is generally expected) at the National Chemical Laboratory, D.S.I.R., Teddington, Middx., for work on general inorganic chemistry, microanalysis, electro-chemistry, chemical thermodynamics and corrosion—The Ministry of Labour, Technical and Scientific Register (K), 26 King Street, London, S.W.1 quoting Ref. F.123/0A.

Hospital Physicist to the Radiotherapy Department—The House Governor, St. Mary's Hospital, Paddington, London, W.2.

Laboratory Technician in the Agricultural Botany Section of the Department of Agricultural Sciences—The Secretary, University of Nottingham, School of Agriculture, Sutton Bonington, Loughborough.

Lecturer or Assistant Lecturer (man or woman graduate, preferably with teaching experience) in Physics in the Training Department—The Warden, Goldsmiths' College (University of London), New Cross, London, S.E.14.

Mathematicians (with a university degree and experience in working with digital computers) with the European Organization for Nuclear Research—CERN, Geneva, for the analysis and programming of various computing problems, in particular problems of numerical analysis on a Ferranti Mercury and IBM 704—The Ministry of Labour (E.9), 26–28 King Street, London, S.W.1.

Physical Chemists (with a good honours degree and preferably some postgraduate research experience), to carry out fundamental work on the reaction between metals and water at high temperatures—The Director, Arthur D. Little Research Institute, Inveresk, Midlothian, Scotland.

Research Assistant (graduate, preferably with experience in microanalytical techniques and chromatography), for work on biosynthesis and identification of steroid hormones in the adrenal gland—Mr. P. J. Ayres, Barnato Joel Laboratories, The Middlesex Hospital, Mortimer Street, London, W.1.

Research Assistant (honours B.Sc. with experience in blood grouping, biochemistry, bacteriology or mammalian genetics), for work on transplantation immunity, including mouse blood group genetics, C.F., skin transplantation—Dr. H. B. Amos, Roswell Park Memorial Institute, Buffalo 3, New York, U.S.A.

Scientific Officer (graduate, preferably in physics, and capable of maintaining and developing the heart lung machine and electronic and other research apparatus) to assist in developments related to cardiac surgery—The Assistant Administrator, Radcliffe Infirmary, Oxford.

Senior Scientific and Scientific Officers (with a first- or second-class honours degree or equivalent in science, engineering or mathematics), for a very wide range of research and development work, including solid state physics, radio astronomy, advanced computing techniques, and electronics and radar—The Director, Royal Radar Establishment, Malvern, Worcs.

ACADEMIC FREEDOM AND UNIVERSITY STANDARDS

IN contrast to the protests, so far unsuccessful, against the infringement of university autonomy in South Africa by the Union Government's Extension of University Education Act, which is universally recognized throughout the academic world as striking against the fundamental conception of a university, a recent *Bulletin of the Committee on Science and Freedom* (No. 14; February 1960) records a successful outcome to a storm of protest from academic and public opinion in Queensland. This was against a Government measure which attempted to establish an officially sponsored appeal board through which the Government could control university staff appointments. This outcome is perhaps the more encouraging in that it demonstrated the existence of an unexpected number of allies in a community where generally graduates—and also scientists, as the Murray Committee's report on Australian universities has shown—are still a small minority and one not held in high enough repute. It should be noted, however, that freedom of platform and Press is far more of a reality in Australia than in South Africa, and this, as Prof. T. K. Ewer shows in the article referred to above, is an important factor when a vital liberty is threatened.

Prof. Ewer describes how the threat arose when the Government of Queensland introduced in 1957 the University of Queensland Acts Amendment Act, 1957. Since the eight universities in Australia, except those of Sydney and Melbourne, are almost wholly dependent on Government funds, the legislation under which they operate seeks to assure strong Government representation on the governing bodies. This Act incorporated a number of amendments which were acceptable to the Staff Association and to the Senate, although a request of the former for three representatives on the Senate was unacceptable to that body, which nevertheless supported the principle of direct representation of staff. This, however, was limited to one member, and so far, in spite of the large expansion of university staff in the past decade and strong representations by the University Staff Association to the Minister of Education, this number has not been increased to the suggested three. In fact, the lack of sympathy shown by Government representatives on the Senate to such matters as an acceptable superannuation scheme, staff housing and the maintenance of parity in salary scale with the Universities of Sydney and Melbourne emphasize both the importance of an informed and alert public opinion and of the comments of the Murray Committee. The expenditure by the Australian Government in the next twelve years of £A20 million recommended by the Murray Committee will not by itself suffice to remove the shortage of scientists and technologists in Australia in academic or other employment, unless their work is appreciated by the community and paid for in accordance with its value.

The real threat described by Prof. Ewer, however, arises from Sections 25 and 31 in the Act, which stated the principle of allowing appeals, to be made to a specially constituted appeal board, against academic and non-academic appointments made by the University and also against disciplinary action. This provision was not to apply to the offices of vice-chancellor or registrar, but the composition of the appeal board raised the main criticism and opposition within and without the University. This was to consist of three members: one appointed by the Government, who was to be chairman; one appointed by the Senate; and one appointed by the Staff Association. These provisions caused the most vigorous protest throughout Australia; it is not quite clear how the blunder was made, but the processes of democracy saved the day.

Without going into the full details, it may be noted that a public meeting of some 2,400 people in the City Hall, Brisbane, passed with acclamation a resolution stating that the provision of an appeal board is "a direct threat to academic freedom and to academic standards of the university; departs from the tradition and procedures of universities within the British Commonwealth; is a great disservice to the interests of the people of Queensland". Pointed reference was made at the meeting to the threat which political interference with academic appointments offered to recruitment, particularly for professorships and senior posts, where reliance is still largely on overseas applicants. The defeat of the Government in a general election, however, and return of a new Government to power was followed by repeal of the appeal board provisions on December 17, 1958, and the new University of Queensland Acts Amendment Act, omitting the appeal board provisions, was proclaimed on August 11, 1958.

This unexpected attack on the University's autonomy has been followed by much discussion among the University staff, and the Professorial Board reconsidered the methods hitherto used for making appointments at all levels. Proposals were framed to ensure that every applicant for a new post on the University staff would be interviewed by the selection committee; the existing system of committees and referees is much the same as that employed in other British universities. The vital lesson of the episode, however, seems to be the importance of public understanding and the existence of effective democratic institutions.

It is the absence of these in South Africa that has been responsible for the passing of the unfortunate Extension of University Education Act and for its operation. Already eight members of the staff of the University College of Fort Hare have been dismissed by the South African Government under the Act, without reason being given; and it seems clear that opposition to government policy will now be regarded as grounds for dismissal and that the members of staff thus dismissed, who include the registrar, five professors, the librarian and a lecturer, are the first victims of the political control of university institutions for non-white peoples. Speaking at the meeting of the Tunis study group of the Committee on Science and Freedom on "Freedom and Responsibility: the Role of the Scholar in Society" in April 1959, Dr. E. G. Malherbe maintained that the idea of a university completely controlled by the State was repugnant to South African men who had learned to value the traditional British system of freedom and autonomy. While, however, the Act would affect adversely the recruitment of staff of good quality and thus tend to debase South Africa's academic currency, its most serious effect would be the exclusion of non-white students from existing universities. Unless the Government instituted a very elaborate system of bursaries, it was difficult to see how the millions of non-whites who are living outside the projected Bantustans, and are completely integrated into the economy of the white people, would have any chance to obtain a university education. Apart from considerations of autonomy and academic freedom, the issue would become economic. South Africa, for a civilized country, has a very low national income per head, and it is difficult to see how she could aspire to multiply university institutions merely in the interests of preserving the ethnic identity of peoples who have evolved no written language and whose culture is riddled with witchcraft and magic.

Dr. Malherbe was confident that, apart from this principle of exclusion in the new legislation, the academic freedom and autonomy of the existing universities of South Africa continue to stand as high as in any country in the world; but with these dismissals at Fort Hare before us it may well be doubted how long this will last. The free society anywhere depends for its strength upon the exercise of civic responsibility by its members. and though the academic community can play a major part by the manifestation of courage and strength of conviction in maintaining the vigorous growth of the ideal and reality of freedom, it cannot continue indefinitely to function as a community unless those qualities command sufficient respect among the public at large to ensure maintenance of the essential conditions of academic freedom of teaching, investigation and appointment. The conference at which Dr. Malherbe's paper was given provided encouraging evidence of the extent to which the idea of academic freedom has taken root, and at the present time it is particularly interesting to note this in the papers by Prof. B. A. Fletcher on the university and society in Central Africa, by Prof. E. Njoku on the relation between university and society in Nigeria, and by Dr. H. A. Oluwasanmi on the scholar and society in Nigeria.

Prof. Fletcher touched briefly on the way in which the University College of Rhodesia and Nyasaland, at Salisbury, is seeking to serve its society in respect of teaching, research and intellectual guidance, emphasizing that in industry, politics and religion it should leave leadership to others. It can both serve society and nourish itself by research and collaborative inquiry in the major fields of science, the social sciences and education, though these are not the only avenues. It was clear enough that Prof. Fletcher's vision of the service a university can render its society can only be realized in a university free from control by Government or any external agency, and free to determine for itself what it shall teach and whom it shall admit, freedoms which in general, as Dr. J. W. Cook observed in an introductory paper on university traditions with particular reference to the British Commonwealth, can only be safeguarded if the academic community has a large measure of control over appointments to its own body.

Prof. Njoku was optimistic that, given proper cultivation, academic freedom should root strongly in Nigeria, and Dr. Oluwasanmi, observing that the Western university tradition is still new in Nigeria, pointed out that, though Ibadan University College derives the bulk of its finances from the State, it has succeeded in maintaining its academic autonomy. It is essential, however, he said, that such university institutions in multi-racial societies should increasingly draw their inspiration from the environment in which they live and function if they are to accept the additional, if non-traditional, function of creating conditions from which a national, as distinct from tribal or racial, identity can be forged. This means that such institutions must also give more attention to those unexplored regions of knowledge that emphasize the common elements of the diverse cultures of the territories in which they function.

There was no tendency at this meeting to ignore the dangers which political and other conditions offer to the realization of these ideals: they were explicitly faced by both Prof. Njoku and Dr. Oluwasanmi, and equally by Dr. Cook, who put his finger on some of the obstacles which the surging tide of nationalism, for example, can raise. While it is easy to sympathize with the desire to foster the use of national languages, it can be an important factor in preventing the attainment of satisfactory standards in a university as well as hinder the free exchange of information and thought with the Western world, particularly in science, where a substantial proportion of original literature is published in English. A university has a duty to guard against any action which might weaken it in its pursuit of learning and the search for knowledge in the less advanced countries, no less than in the advanced and highly industrialized countries.

Dr. Cook said he is convinced that the policy adopted in 1945 in developing these new university institutions in the Commonwealth countries had been right. High academic standards have been established from the start, staffs of high calibre appointed, and significant and important contributions to new knowledge, often related to the needs and opportunities of the regions, have been made. There has also been a small but steadily increasing flow of graduates who will have a profound influence on the development of their nations.

All this will be of increasing importance as more territories move to independence and increasing efforts are made to solve the problems of government in multi-racial territories. More university institutions will probably be required, and Dr. Cook wisely suggests that these need not be conceived on precisely the same lines as the existing institutions. There is room for experiment, and perhaps especially in ways that have closer regard to the financial resources of newly independent countries. What matters most is that in giving careful attention to the traditional cultures of the countries and to their expanding needs, high academic standards should be maintained and the university traditions which have stood the test of time should be scrupulously observed. For that reason alone, universities in the rapidly developing countries should be the more careful not to become embroiled in political controversy, and to ensure that their legitimate studies of political, economic and social questions should be undertaken in no partisan spirit. Nor may it be too much to hope that in the measure in which these new universities meet the needs of the independent territories, and especially of the multi-racial communities, they will demonstrate the futility of the South African Government's present university policy, and perhaps even cause its reversal before South African academic traditions are destroyed and irreparable damage done to its universities.

ANTIBIOTICS FROM A NOVEL ANGLE

Antibiotics

Their Chemistry and Non-Medical Uses. Edited by Dr. Herbert S. Goldberg. Pp. x+608. (Princeton, N.J.: D. Van Nostrand Company, Inc., London: D. Van Nostrand Company, Ltd., 1959.) 112*s.* 6*d.*

In a foreword to this very welcome book, Dr. Paul R. Burkholder, the discoverer of chloromycetin, says: "For some time past, all of us have been certain about one aspect of antibiotic science and that is the great need for a new kind of book which would summarize the remarkable advances that have taken place recently" and the reviewer, who is in full agreement, would like to add "particularly in their non-medical uses". The book is the work of six American authors, all of whom are well known in antibiotic science. It consists of an introduction and six chapters, each of which is a complete monograph in itself. An unusual and very useful feature of the book is the large number of references—some two thousand in all—occupying a total of 261 pages and amounting to about 43 per cent of the book. The references given in the introduction (216 in number) and in the opening chapter on the chemistry of antibiotics (566) give the full title of the paper referred to in the text together with the usual details. In the remaining five chapters, however, very informative abstracts of the contents of the papers are also given.

The introduction deals with the history of antibiotics, their economic import, natural occurrence, effects and mode of action. The opening chapter (84 pages) admirably succeeds in summarizing the chemistry of the penicillins, streptomycin and related antibiotics, chloromycetin, the tetracycline group, the macrolides, novobiocin, polyene and polypeptide antibiotics.

The growth stimulation and general effects on the nutrition of domestic animals and birds is discussed in the following chapter (59 pages; 545 references). The magnitude and importance of this aspect of antibiotics may be judged from the fact that in 1954 more than 20 per cent (value 25 million dollars) of all antibiotics produced in the United States were used in animal feed supplements.

Botanists, and particularly plant pathologists and physiologists, will find the article on "The Influence of Antibiotics on Plants and Plant Disease Control" (78 pages; 376 references) a full and authoritative account of the subject. It is certainly surprising to learn that at least thirty-nine different antibiotics have been studied in the control of plant bacterial and fungal pathogens.

The texts of the remaining three chapters are relatively short. Chapter 5 (22 pages; 283 references, which unfortunately are not numbered) deals with antibiotics in food preservation, that is, in canned foods, fresh foods including meats, poultry, fish, fruit and vegetables, dairy products and yeast fermentations. Laboratory workers in microbiology will particularly welcome chapter 6 (18 pages; 96 references) on the uses of antibiotics in the isolation in pure culture and cultivation of micro-organisms from the complex mixtures in which they normally occur, for example, bacteria, fungi including plant pathogens, protozoa, viruses and rickettsiae. The book closes with an authoritative article (22 pages; 75 references) on the public health significance of non-medical uses of antibiotics, particularly in foods for human consumption. We may however take some comfort from the author's opinion that "one must conclude that the seriousness of the public health hazards of antibiotic residues in food has been overstated".

I believe that this book will completely satisfy the need expressed earlier for a new kind of book on antibiotic science. HAROLD RAISTRICK

BIOCHEMICAL PRACTICE

Biochemical Preparations

Vol. 6. Edited by Carl S. Vestling. Pp. ix+105. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1958.) 42*s.* net.

Methods of Biochemical Analysis

Vol. 7. Edited by Prof. David Glick. Pp. ix+353. (New York: Interscience Publishers, Inc.; London: Interscience Publishers, Ltd., 1959.) 72*s.*

THE latest volume in the valuable series of "Biochemical Preparations" contains detailed descriptions of carefully checked methods for the preparation of the following: crystalline animal cytochrome *c*, deoxyribonucleic acid, 2,3-diphosphoglyceric acid, L-α-glycerophosphorylcholine, 3-

hydroxyanthranilic acid, β-hydroxy-β-methylglutaric acid, insulin, lanosterol, leucine amino-peptidase, α-methylserine and *bis* (hydroxymethyl) glycine, crystalline horse oxyhæmoglobin, old yellow enzyme, crystalline papain and benzoyl-L-argininamide, crystalline muscle phosphorylases *a* and *b*, phosphoserine, rat liver ribonucleic acid, ribulose diphosphate, and DL-tryptophan-7a-C^{14}. A few minor criticisms are worthy of mention. The excellent practice of including structural formulæ was apparently overlooked in the description of the preparation of lanosterol. It is regrettable that anachronisms such as "Twenty-one and two-tenths grams of L-arginine hydrochloride . . ." (p. 64) and "Two and six-tenths kilograms of the washed and dried yeast . . ." (p. 55) are preferred to the more usual form. Grammatical errors, such as "The enzyme is extracted from dried brewer's bottom yeast, impurities removed by precipitation with basic lead acetate, and the enzyme further purified by fractionation . . ." (p. 54), and "The combined eluates are dialyzed and the adsorption procedure repeated . . ." (p. 57), were surprising.

The editorial board clearly makes strenuous efforts to replace older methods in earlier volumes by better methods, as illustrated by the inclusion of improved preparations of muscle phosphorylase and cytochrome *c*. There must be an interval before this is possible, however, and it is suggested that an appendix in each volume might give references to recent descriptions in the original literature of new methods of preparation of compounds, which have formed the subject-matter of earlier volumes of this series. One example will suffice; the preparation of leucine aminopeptidase has been simplified (Folk, Gladner, and Viswanatha, *Biochim. Biophys. Acta*, 36, 256; 1959) since this volume was published, and, although not checked by independent workers, reference to the method would be helpful in succeeding volumes. There is a valuable list of compounds of biochemical interest which have appeared in "Organic Syntheses" up to Vol. 38.

The volumes of "Methods of Biochemical Analysis" have rightly assumed a position of authority in biochemical literature. The latest volume deals with eight topics. Various modifications of the technique of immunoelectrophoresis are described in detail by P. Grabar, who is a pioneer in this field. This will please many workers, for much of the original literature appears in recondite journals. Two articles of considerable value to toxicologists describe the analysis of basic nitrogenous compounds (A. S. Curry) and the determination of ethyl alcohol in blood and tissues (F. Lundquist). The latter would provide the Minister of Transport with some interesting home-work. Workers in the lipid field are catered for by two chapters entitled "The Determination of Inositol, Ethanolamine, and Serine in Lipides" (J. M. McKibbin) and "The Assay of Lipoprotein Lipase *in vivo* and *in vitro* (E. D. Korn). L. B. Jaques and H. J. Bell have given a detailed description of the bewildering variety of methods for the extraction and determination of heparin. This article, however, contains the astonishing statement that "Barium due to its high molecular weight will dilute and hence reduce the values". The rather short account of the determination of creatinine and related guanidinium compounds (J. F. Van Pilsum) could have included a more critical discussion of the numerous colorimetric methods for arginine determination. Several recent methods (Satake and Luck, *Bull. Soc. Chim. Biol.*, 40, 1743; 1958: Cerriotti and Spandrio, *Biochem. J.*, 66, 603; 1957: Janus, *Nature*, 177, 529; 1956) are not mentioned. The recently developed technique for spectrophotometric study of translucent materials, which employs an opal glass in the light beam, is described by Shibata. Theoretical principles are considered, and suitable attachments for commercial spectrophotometers are described.

D. T. ELMORE

THE WAY TO THE STARS

Advances in Astronautical Sciences

Vol. 1: Proceedings of the Third Annual Meeting of the American Astronautical Society, December 1956. Pp. vi+177. Vol. 2: Proceedings of the Fourth Annual Meeting, December 1957. Pp. viii+456. Vol. 3: Proceedings of the Western Regional Meeting, August 1958. Pp. viii+547. Vol. 4: Proceedings of the Fifth Annual Meeting, November 1958. Pp. ii+460. (New York: Plenum Press, Inc.; London: Chapman and Hall, Ltd., 1957, 1958 and 1959.) 80*s*. net each volume.

ASTRONAUTICS, rejoicing in respectability and a far-flung dependence on numerous aspects of science and technology, finds itself admirably suited to congresses and conventions. The records of the proceedings tend to be impressive, expensive and distinctly daunting to the general reader, however great his specialist knowledge in one or two related fields.

The present volumes are no exception: they record the proceedings of four separate meetings of the American Astronautical Society held in December 1956 (Vol. 1), December 1957 (Vol. 2), August 1958 (Vol. 3) and November 1958 (Vol. 4). Each volume costs 8 dollars which, by some curious transformation process, becomes £4 in Great Britain. Taken together, they comprise 143 papers with some abstracts and supplementary lectures, covering 1,640 pages and weighing 8 lb. Vol. 1, which is less than half the size of any of the others but costs just as much, begins with a short paper by C. S. Draper on "Education in the Astronautical Sciences". He suggests a 4–6-year curriculum likely to overwhelm all but the most able and enthusiastic student. Many of the following papers are speculative rather than specific, and the volume ends with much discussion about the twin or clock paradox and relativity.

The remaining three volumes are all post-*Sputnik* 1 and reflect the enormous impetus that the launching of the world's first artificial satellite gave to American astronautics. An appreciable proportion of the latter volumes consists of sober theoretical analyses of the motions of space vehicles, communication and navigation problems, reports of full-scale and laboratory experiments and the development of ideas based on verified facts or current techniques. In all these matters the exposition is generally excellent, and we are—to use a somewhat inappropriate simile—on solid ground. Some of the remaining papers are futuristic and here the reviewers find themselves rather at a loss. In most fields of engineering, development is achieved by making an accurate estimate of the worthwhile magnitude of the next step forward, on technical and economic grounds. One can easily think of examples in aviation where the steps have been either too conservative or too bold. When reading about ideas in astronautics, the practical applications of which are often exceedingly complex but which advance very rapidly, it is difficult to judge just how far ahead the author may be thinking. It certainly seems that some of the brains devoted to contemplating future developments have taken their thoughts well beyond the next few feasible technological steps: in the absence of a yardstick, it becomes difficult to distinguish between far-ranging speculation or suggestion and something very close to science fiction. One can only marvel at the opulence of an industry capable of supporting gentlemen who devote their thoughts to "Assembly of a Multi-Manned Satellite" particularly on reading sentences such as: "Imagine then a space-suited worker chasing tools and materials on different orbits". Of course, such papers are intensely interesting, particularly when written in concise English, as is this particular example. Papers using turgid prose are fortunately in the minority.

One is therefore caused to question the object of all this activity, and is gratified to find that Dryden's contribution to the introduction of Vol. 4 is entitled "Space Exploration and Human Welfare". It is probably unfair to expect a concisely stated objective: the paper lists a few minor benefits to television and meteorology, says quite bluntly that we do not know the ultimate role of space vehicles in transportation and makes reference to the desire for increasing our knowledge of the universe for peaceful purposes. It seems quite possible that something is left unsaid.

The binding and paper of these volumes are excellent: unfortunately the reproduction of the contents is very variable in quality. The first three volumes consist of reproductions of typescript and handwritten equations. The diagrams reproduce well, but most of the photographs are very unsatisfactory. Volume 4 reverses this situation. The print and photographs are generally good but the diagrams, while clear, are reproduced on far too small a scale.

These volumes contain much valuable information and would be useful additions to a generously endowed library.

F. G. IRVING
J. L. STOLLERY

PLANT PHYSIOLOGY IN THE FIELD

Plants and Environment

A Textbook of Plant Autecology. By Prof. R. F. Daubenmire. Second edition. Pp. xi+422. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1959.) 56*s*. net.

THIS is a revised edition of a book originally published in 1947. The format and the heavy glossy paper are typically North American. The text is enriched by many photographs and diagrams; some of the photographs appear to have suffered in reproduction.

As Prof. Daubenmire's introductory definition of autecology in his preface shows, the sub-title of this book is misleading to British ecologists, most of whom would define autecology as the study of the ecology of a single species. This book, on the contrary, deals with the environmental factors which affect plants. Seven factors—soil, water, temperature, light, atmospheric, biotic, and fire—are given a chapter each, and two further chapters deal with "The Environmental Complex" and with "Ecologic Adaptation and Evolution". Much useful information on recent work is included, particularly in the fields of plant physiology and geneecology. Pursuing his interpretation of autecology, the author discusses the environmental factors as they affect particular plants, but the plant examples are chosen at random, and nowhere is there an integrated study of a single species such as a British ecologist would expect from "A Text-book of Plant Autecology". Nor is there any reference to the plant as part of a natural community, nor any analysis of different types of vegetation, nor any reference to the distribution of plants and historical ecology; presumably all these subjects fall within the author's definition of synecology and are deliberately excluded, but it is surely impossible to study the autecology of a species without at least considering these aspects. The approach to ecology presented in this book is therefore that of the experimentalist rather than that of the naturalist; indeed, "Plant Physiology in the Field" would be an apter title than "A Text-book of Plant Autecology".

Within these limits, the book will be of interest to plant geographers and should prove a useful reference book to students of botany. It provides data on many subjects which are relatively unfamiliar in Britain, such as frost action on soils, anatomical details of frost damage and sun scorch, anatomical effects on trees of the adverse habitats encountered at the upper timber-line of natural forest, and the ecological effects of widespread fires. Sections in the chapters on water factors and light factors provide a very useful bridge between plant physiology and ecology, and there is much miscellaneous but useful information in the chapters on atmospheric factors and biotic factors.

W. TUTIN

NON-INDIGENOUS ANIMALS OF GREAT BRITAIN

The Ark in Our Midst

The Story of the Introduced Animals of Britain—Birds, Beasts, Reptiles, Amphibians, Fishes. By R. S. R. Fitter. Pp. 320+16 plates. (London: William Collins, Sons and Co., Ltd., 1959.) 18*s*. net.

THIS is an ambitious book for in it the author sets out to cover a wide field, to survey the non-indigenous animals of the British Isles, that is the mammals, birds, reptiles and amphibians, which owe their inclusion in our fauna to the agency of man, creatures so diverse as the edible frog, the pheasant and the grey squirrel; and he does not restrict himself to those that have been successfully naturalized but includes species that have failed to establish themselves, pointing out that they are not the less interesting because they lack the necessary adaptability. Mr. Fitter tells us that the failures have been many and in excess of the successes, though the latter have often been spectacular with far-reaching results, for example, the manner in which the rabbit, the rat and the grey squirrel have colonized Great Britain.

Although we may be sure that man was the agent concerned in the arrival here of a number of creatures, although we may be positive they did not get here 'under their own steam', it is by no means easy to ascertain in each case how the deed was done, still less when it was done, even when it must have been well within the historic period.

It has long been the custom to give great credit to the Romans as importers of animals, much of which credit they undoubtedly deserve; yet evidence is singularly lacking as to what beasts, birds, fishes and so on they really did bring across the English Channel and naturalize in Britain. It is said that they introduced the pheasant; yet the bird bones found in Romano-British settlements have all been identified by experts as belonging to the domestic fowl. But we do find evidence that the pheasant was in Britain by Norman times. In a charter of 1098, the Bishop of Rochester assigned to that City among other things sixteen pheasants from certain Kentish manors, and in 1100 the Abbot of Malmesbury was given a royal licence to kill hares and pheasants, which latter we may presume were as naturalized and wild as the hares.

Mr. Fitter's industry in the collection of facts regarding the arrival in Britain of this variety of creatures has been immense. His lengthy volume is packed with information, the facts being clearly and concisely related, resulting in a most useful book that will be valuable for reference for many years to come.

FRANCES PITT

THE ZOOGEOGRAPHY OF WESTERN NORTH AMERICA

Zoogeography

Edited by Carl L. Hubbs. (A Symposium presented on August 26–27, 1957, at the Stanford University Joint Meeting of the American Institute of Biological Sciences and the Pacific Division of the American Association for the Advancement of Science, and a Symposium presented on December 28, 1957, at the Indianapolis Meeting of the American Association for the Advancement of Science.) Pp. x+509. (Publication No. 51.) (Washington, D.C.: American Association for the Advancement of Science; London: Bailey Bros. and Swinfen, Ltd., 1958.) 108*s*.

THIS volume contains seventeen full articles dealing with the wide variety of topics to be expected in two symposia on zoogeography. It does not deal much with the subject as a whole, and the title is really misleading, since most of the articles are concerned only or mainly with the western part of North America. The topics covered include the present and past distribution of land areas, habitats and climate (Tertiary and Pleistocene), physiological tolerance of vertebrates as bearing on distribution changes, Tertiary mammals and birds, Amphibia and reptiles, freshwater fish and invertebrates, Orthoptera, Dermaptera, longicorn beetles, and butterflies. The standard of scholarship is high, but inevitably for most of these groups more can be said of their present than of their past distribution, and we are constantly aware of the central difficulty of reconstructing faunal histories without the sort of fossil records that exist for the mammals, where the story can be best authenticated. Nevertheless, this volume is really valuable in drawing together into a coherent form a very large amount of information, and it represents much concentrated and intelligent research. As a great deal of the material upon which zoogeography is based inevitably accumulates in a rather haphazard manner, through the results of expeditions, museum bulletins, and so on, it is necessary to take stock at intervals and in this sort of way. It does not appear, however, that any very new ideas were brought to the surface by these symposia. This being so, it is a pity that the only index is one of Latin names. Anyone who wants to find other subjects will have to search the 477 pages of text.

To the general reader, perhaps the following four papers are the most useful. P. B. King traces the growth of modern surface features in Western North America, through the comparatively small deposition and mountain movements up to Jurassic times, and then the major upward Cordilleran movements and their aftermath. D. E. Savage gives a thorough conspectus of the fossil land mammals and their bearing upon Western faunal history. R. R. Miller has a very informative paper on the present distribution and origins of freshwater fishes of the West. A large paper on Pleistocene palæo-ecology by P. S. Martin covers a wider scene, including all North America, the West Indies and the Galapagos Islands, and takes in the arrival of man, and his influence on the fauna.

BUTTERFLIES AND MOTHS

Les Papillons

Par Guy Mathot. ("Que Sais-je ?" No. 797.) Pp. 128. (Paris: Presses Universitaires de France, 1958.) n.p.

"LES PAPILLONS" is not 'just another book on Lepidoptera'. There are very few books which aim at giving a popular account of world Lepidoptera and, in spite of the small size of this book (the page size is similar to the "Wayside and Woodland" series), it covers the subject very well.

There are six chapters: from egg to adult; morphology and anatomy of the imago; infra-specific variation; systematic studies on the principal groups of the world fauna; biogeography of the Lepidoptera; summary of biological studies.

The drawings in the book are not of a very high standard and the reproduction is poor, although this may be due to the poor quality of the paper. The text is very detailed in some parts, giving, for example, the chemical composition of various pigments, chromosome numbers and a table of wing loadings (p. 33). Some of the detail could have been left out in favour of other information. The table of wing loading (p. 33) and that (p. 43) giving the respiratory quotient seem unnecessary.

Small errors occur. The classification used (pp. 56–57) is not entirely satisfactory. The use of "Pyralidididoidea" and "Pyralididae" instead of the shorter Pyralidoidea and Pyralidae is irritating. A few spelling mistakes have occurred, *A. kühniella* Zell. is *kuehniella* (p. 81). The genus "*Paraponyx*" (p. 81) is always wrongly spelled and should be *Parapoynx* (Hubner, 1825). Some of the nomenclature is out of date (for example, *Lycaena* is used p. 52) instead of *Polyommatus* (Latreille, 1804).

The lack of authors' names after the species anywhere in the book is regrettable. Even in a book popularizing the subject the student should be correctly instructed, and in this case the author's name should have been given, at least where the species was first used.

In spite of these criticisms, the book contains a wealth of information unobtainable in any book of comparative size. It will interest all collectors who wish to study more than just British Lepidoptera.

PAUL E. S. WHALLEY

The Freshwater Life of the British Isles

A Guide to the Plants and Invertebrates of Ponds, Lakes, Streams and Rivers, with an additional chapter on the Vertebrates. By John Clegg. Second edition. (Wayside and Woodland Series.) Pp. 352 + 67 plates. (London and New York: Frederick Warne and Co., Ltd., 1959.) 21*s*. net.

THIS popular book, first published in 1952, deals in broad outline with the basic information necessary to an understanding of limnology; it has proved its worth as an elementary text for teachers and students and, in particular, for those attending courses at the field study centres.

This new edition has given Mr. Clegg the opportunity to eliminate some errors which had crept into the first edition and to include some new results that had become available since 1952. Some colour plates by Mr. Ernest C. Mansell are noteworthy additions, those on Mollusca being particularly good. The opportunity might also have been taken to provide more satisfactory colour photographs both of the natterjack toad and of the common toad.

Although a great many animals and plants can be identified with the aid of this book, there are no keys, and it is not primarily concerned with identification down to species. Illustrated extended keys (of too recent date to have been included in the revised bibliography) are now available and can be used in conjunction with this volume, but they do not pretend to provide a comprehensive, well-balanced introduction to limnology such as the beginner will find in Mr. Clegg's book. W. J. Rees

The Future of Non-Ferrous Mining in Great Britain and Ireland

(Proceedings of a Symposium arranged by the Institution of Mining and Metallurgy in collaboration with the United Kingdom Metal Mining Association, held on 23rd and 24th September, 1958, at the Federation of British Industries, London.) Pp. xxxvi + 614. (London: The Institution of Mining and Metallurgy, 1959.) 60*s*.

THE main scientific results of the symposium organized jointly by the Institute of Mining and Metallurgy and the United Kingdom Metal Mining Association have already been reported briefly in *Nature* (Oct. 25, 1958, p. 1136). Publication of the Proceedings, delayed by the printers' strike, has now been achieved. The single volume contains the text of the fourth Sir Julius Wernher Lecture, delivered as a prelude to the symposium by Mr. Anton Grey. This is followed by thirty-two original papers, most of which had been issued as pre-prints to members, together with verbatim reports of the discussions at the two days of meetings. Sixteen of the papers are devoted to descriptions of the tin, copper, lead, zinc, fluorine and barium deposits of the British Islands, the most comprehensive review of the epigenetic mineral deposits of Britain so far assembled in a single volume. History, geology, production and potential are dealt with in each of these papers. Most of the ore-fields have been described before, some of them in some detail, as for example in the Geological Survey Memoirs of the Northern Pennine Ore-field (1948) and South-Western England (1956), some only in a general fashion. The present publication gives an up-to-date picture of an industry which is now no more than a shadow of its former self. The purpose of the symposium was to consider whether resources of the non-ferrous minerals remain in the British Isles after more than 2,000 years of exploitation; whether these are worth finding, and if so how they can be located. With these points in view, the other papers and discussions were devoted to modern techniques for prospecting—geophysical, geochemical, radiometrical—and to considerations of economics and ownership. If the conclusions can be summed up in a single phrase, they are that deposits as yet undiscovered may be expected to remain; that in all but a few cases the search for these would be so speculative as to need some form of State support; and that when they are found the value of the deposits against the current economic background cannot be said to be assured.

K. C. Dunham

Infant Mortality in India, 1901–55

A Matter of Life and Death. By Prof. S. Chandrasekhar. Pp. 175. (London: George Allen and Unwin, Ltd., 1959.) 20*s*. net.

IN writing this book Prof. Chandrasekhar essays the difficult task of being three persons at once. As director of the Indian Institute for Population Studies he makes clear the inadequacy of available statistics. Though the wealth of material in the decennial censuses of India since 1881 is well known, essential basic data such as total number of births, or total number lost under one year, are not available. In the second place the author, as a distinguished social scientist, has little difficulty in showing how unfavourably India compares with so many other countries. Though the infant mortality-rate is shown as having dropped from 215 per 1,000 live births in 1901–05, to 116 in 1951, the latter figure is compared with such examples as 29 in the United States or 27 in England and Wales. In fairness it is noted that infant mortality is still believed to average 300–500 per 1,000 live births over most of Africa. In the third part of the book the author, as social reformer, claims that the nation's children are too precious to be wasted by premature death, that the nation's efforts should be directed to the ideal of reducing the present infant mortality-rate to something like 20 per 1,000 live births. Family planning with a limitation to, "say, three under normal circumstances spaced, say, three years apart," is mentioned incidentally rather than made a focal point.

L. Dudley Stamp

Second Conference on Co-ordination of Galactic Research

Edited by A. Blaauw, G. Larsson-Leander, N. G. Roman, A. Sandage, H. F. Weaver and A. D. Thackeray. (International Astronomical Union Symposium No. 7, held at Saltsjöbaden, near Stockholm, June 1957.) Pp. viii + 93. (Cambridge: At the University Press, 1959.) 15*s*. net.

THE first conference on the co-ordination of galactic research was held in 1953 and its report appeared as International Astronomical Union Symposium No. 1; it was devoted to a broad survey of the problems of galactic structure. The second conference was devoted to more detailed problems of particular importance at this time: clusters and associations, the Galaxy as a whole, and the Magellanic Clouds. A good account is given of many aspects of current work as well as discussions of the possibilities for future investigations. Emphasis is laid on the importance of adequate standardization of the photometric systems used by different observers.

ROLE OF INFECTIVE NUCLEIC ACID IN THE PRODUCTION OF ENCEPHALOMYOCARDITIS VIRUS

By Dr. F. K. SANDERS

Director, Virus Research Group, Medical Research Council Laboratories, Carshalton, Surrey

COLD phenol treatment[1] of cells infected by several different animal viruses yields infective material, a major constituent of which appears to be ribonucleic acid[2–7]; in this article such preparations will be referred to as 'infective ribonucleic acid'.

In some cases, infective ribonucleic acid seems to come from the virus itself; but in others to form part of another component, which does not sediment appreciably under conditions which bring down virus[6,7]; in the latter cases phenol at 4° C. fails to extract infective ribonucleic acid from the virus particles themselves, although hot phenol (40° C.–60° C.) may be able to do so[7]. The extracellular fluid into which virus has been released at the end of virus growth in mouse ascites tumour cells infected *in vitro* with murine encephalomyocarditis virus contains a component, sensitive to cold phenol, which is not the virus itself[6]. Such a component might be: (*a*) some kind of cellular structure formed as a result of infection, in relation to which virus is synthesized; (*b*) a precursor of the virus particle itself; (*c*) a product of the abnormal synthesis, which somehow fails to be incorporated into a virus particle; (*d*) a breakdown product of virus particles.

Continuously agitated suspensions of Krebs 2 mouse ascites carcinoma cells, infected with encephalomyocarditis virus *in vitro*[8], were used to follow the appearance of infective ribonucleic acid during virus growth, extracts being made from cells at all stages of the virus growth-cycle up to the beginning of virus release. Infected cells, washed with phosphate-buffered saline, and resuspended at a concentration of 5 × 10^7/ml. in 0·02 M phosphate pH 7·2, were extracted three times with water-saturated phenol. Phenol was removed from the aqueous layer with ether and the ribonucleic acid precipitated by ethanol. The precipitate was washed three times with 67 per cent ethanol/33 per cent 0·14 M sodium chloride and redissolved in 0·2 M phosphate buffer pH 6·8. All operations were carried out at 4° C. and all aqueous solutions except the 0·2 M phosphate buffer contained nickel ions to stabilize the ribonucleic acid; the optimal concentration of nickel was found to be 1 nickel ion per nucleotide, as already found for tobacco mosaic virus ribonucleic acid[9]. A small residual precipitate of nickel phosphate was removed by centrifugation. Ribonucleic acid preparations were mixed with tumour cells and titrated in mice[6], on the day of preparation, although the above method gave a product which retained its original titre for at least 14 days at 4° C., and 24 hr. at 20° C. (Vizoso, A. D., and Burness, A. T. H., personal communication).

In multiply infected cell populations (cells 1 × 10^7/ml.; virus 3 × 10^7/ml.) at 37° C. infective ribonucleic acid could be found as early as 15 min. after infection. Thereafter the level of infectivity rose to a maximum at about 5 hr., when 100–1,000 times the amount present initially was found. Infective ribonucleic acid production is thus practically complete by the time new virus is formed; the latter appears intracellularly at about 4 hr., and then increases to maximum titre 7–8 hr. after infection. Cells begin to die and release this virus 6–7 hr. after infection, and release from the whole population is virtually complete at 12 hr. The extracellular fluid then contains more than 2 × 10^9 plaque-forming units of virus/ml. and a similar number of mouse ID_{50} when titrated *in vivo*.

The increase in infective ribonucleic acid content found during the first hour probably does not involve synthesis of new ribonucleic acid, but represents the formation of an increasing number of virus/cell complexes, in which the ribonucleic acid of the infecting virus becomes capable of extraction by phenol, for cells infected for 2–16 hr. at 4° C. all contain ribonucleic acid with an infectivity corresponding to the level reached in 1 hr. at 37° C., and this level of infectivity is also reached in the presence of inhibitors (see below). Similarly, a fall of about 90 per cent in the infective ribonucleic acid content occurring between 5 and 7 hr. after infection (Fig. 1) need not involve the destruction of infective ribonucleic acid but its progressive inclusion in virus particles whence it cannot be extracted by cold phenol in an infective form.

Effect of Euflavine

Experiments in which virus was grown in the presence of euflavine gave further information about the relationship of the early appearance of infective ribonucleic acid to virus synthesis. In an initial experiment cells (10^7/ml.) were incubated for 1 hr. in the presence of various concentrations of euflavine,

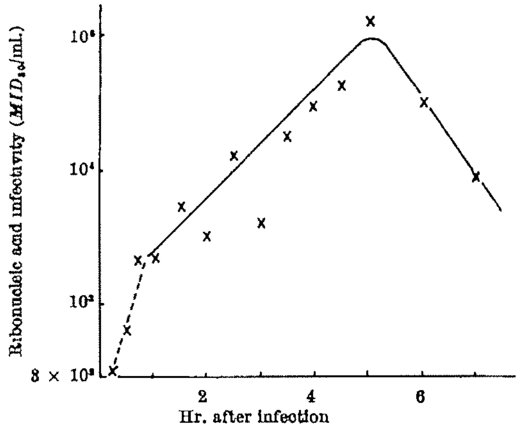

Fig. 1. Infectivity of 'cold phenol ribonucleic acid' at intervals during virus growth

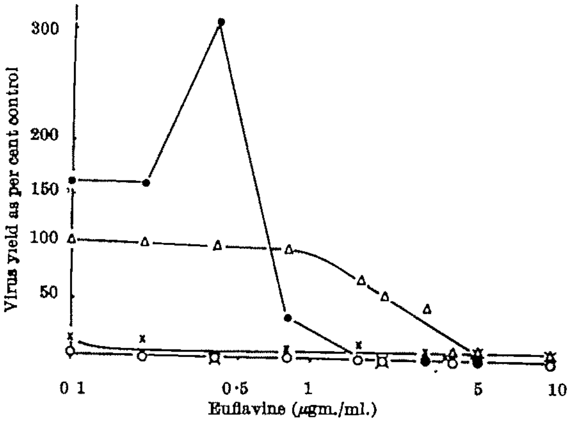

Fig. 2. Effect of various concentrations of euflavine on virus production. ○, plaque-forming units; ●, hæmagglutinin; ×, infective ribonucleic acid; △, cell mortality

all of which were without significant toxic effect upon control uninfected cultures in experiments of similar duration. Virus was then added (multiplicity = 4), and the culture incubated for 16 hr., when the following quantities were measured; (*a*) virus hæmagglutinin concentration, and (*b*) concentration of infective virus (plaque-forming units), in the supernatant fluid; (*c*) the infectivity of ribonucleic acid extractable from the whole culture (cells plus supernatant); (*d*) the number of cells killed by virus multiplication[6,8,10].

All euflavine concentrations tested, even the smallest (0·1 µgm./ml.) virtually suppressed the production of infective virus (Fig. 2); hæmagglutinin production was also inhibited by euflavine concentrations greater than 2 µgm./ml. However, in low concentrations (0·1–0·5 µgm./ml.), hæmagglutinin production was high, probably somewhat increased with respect to the control. Proflavine, a related drug, interferes with a late stage of bacteriophage multiplication—probably that of virus assembly[11,12]—and it is possible that low concentrations of euflavine can similarly disturb the multiplication of encephalomyocarditis virus. Even small amounts of euflavine significantly reduced infective nucleic acid formation, although high doses of the drug failed to reduce the infective ribonucleic acid content below that found in untreated cultures during the first hour after infection. With less than 1 µgm. euflavine/ml. as many cells eventually died as in the control, but in higher concentrations more and more cells appeared to resist the lethal effect of the virus, so that at concentrations greater than 4 µgm./ml., virtually all cells were preserved.

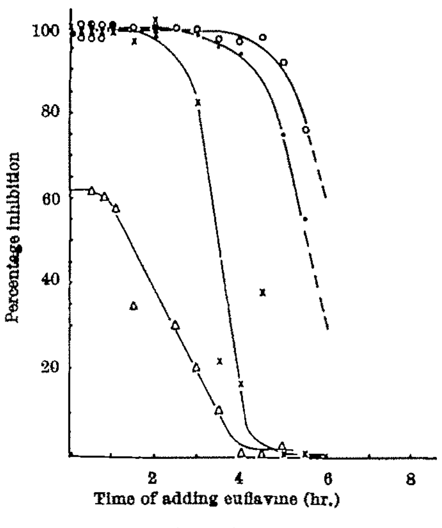

Fig. 3. Effect of adding 5 µgm./ml. euflavine at different times during virus growth. Symbols as in Fig. 2

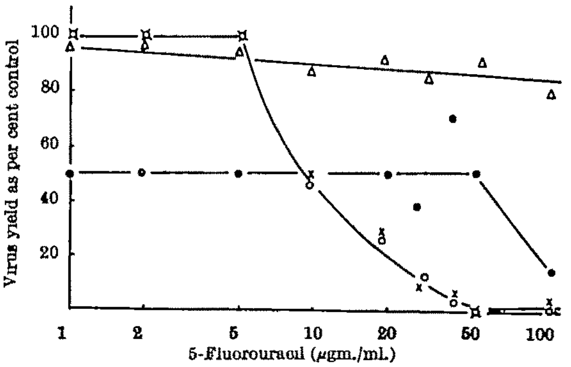

Fig. 4. Effect of various concentrations of 5-fluorouracil on virus production. Symbols as in Fig. 2

Fig. 3 gives the result of an experiment in which 5 µgm./ml. of euflavine was added to ascites tumour cell suspensions at different times after infection. Up to 1½ hr. this dose of euflavine prevented the production of all virus-related substances measured. When given at 4 hr., however, while the production of hæmagglutinin and plaque-forming units was still suppressed, the production of infective ribonucleic acid was normal and the cells died at the proper time. When euflavine was given later than 4 hr., more and more hæmagglutinin was found although even at 5½ hr. after infection there was still significant inhibition of the production of complete virus particles (plaque-forming units). Thus the production of infective ribonucleic acid must be virtually complete by the time hæmagglutinin begins to appear; the latter appears only to be incorporated into plaque-forming virus particles towards the end of virus growth.

Effect of 5-Fluorouracil

This pyrimidine analogue can become incorporated into the ribonucleic acids of animal tissues[13], bacteria[14] and tobacco mosaic virus[15] and it was thus of interest to discover what effect it might have on encephalomyocarditis infective nucleic acid and virus production; all concentrations tested were without significant toxic effect upon the cells under the conditions used. Doses of 5-fluorouracil up to 20 µgm./ml. had little effect on the production of hæmagglutinin and failed to prevent virus-infected cells from dying at the end of the virus growth-cycle (Fig. 4). However, with doses greater than 5 µgm./ml. there was a progressive diminution in the number of plaque-forming units, so that at 50 µgm./ml. or more, less than 1 per cent of the normal number was found. High levels of the drug also affected the production of hæmagglutinin although to a smaller extent. The curve of suppression of infective ribonucleic acid production was very similar to that for plaque-forming units, which suggested that infective ribonucleic acid might actually become incorporated into the virus particle. In further experiments 100 µgm./ml. 5-fluorouracil was added at various times after infection (Fig. 5).

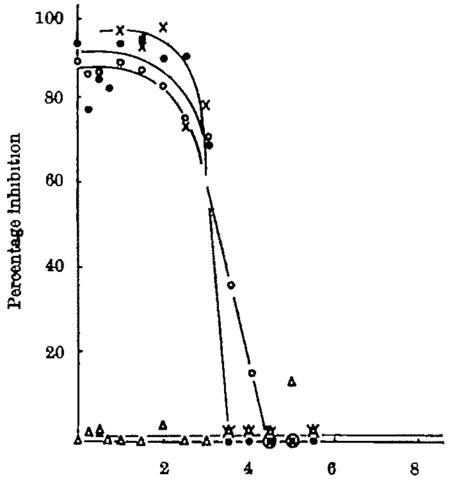

Fig. 5 Effect of adding 100 μgm./ml. 5-fluorouracil at different times during virus growth. Symbols as in Fig. 2

When this amount of 5-fluorouracil was given 1 hr. before virus, there was marked inhibition of hæmagglutinin production and the production of infective ribonucleic acid and plaque-forming units was suppressed; but there was no sparing of the cells. Up to 1 hr. after infection, its effect was the same. With later administration of the drug, however, more infective ribonucleic acid, more hæmagglutinin and more infective virus particles were produced. Addition of the drug at any time after 4 hr. failed to affect the course of virus multiplication. 5-fluorouracil presumably acts during nucleic acid synthesis by replacing part of the uridylic acid residues with their 5-fluoro analogue[14,15]. Anomalous nucleic acid containing this substance is presumably not infectious, and virus particles with such a nucleic acid would not be able to reproduce themselves. The fact that the time-course of suppression by 5-fluorouracil is the same for both these entities suggests that the ribonucleic acid formed between 1 and 4 hr. after infection eventually becomes part of the virus particles. Moreover, since hæmagglutinin production is only significantly affected by 5-fluorouracil when the drug is given during infective ribonucleic acid formation suggests that the newly synthesized ribonucleic acid may act as a centre for the later synthesis of hæmagglutinin.

The multiplication of encephalomyocarditis virus thus probably takes place as follows. Contact of a virus particle with its host cell causes the formation of a virus/cell complex; this can be defined operationally as some alteration in the virus structure resulting from contact with the cell which releases the virus ribonucleic acid in a form extractable by phenol at 4° C. Complex formation presumably involves neither nucleic acid nor protein synthesis since it is not inhibited by either fluorouracil or euflavine, and takes place easily at 4° C. and at 37° C. The next stage seems to be replication of ribonucleic acid carrying the genetic information of the virus, which probably begins at about one hour after infection and reaches a maximum about four hours later; it gives rise to the component described earlier[6], which is the source of the infective ribonucleic acid extracted by cold phenol from infected cells. Only later comes the production of virus hæmagglutinin from 3½ to 6 hr. after infection, and this stage can still be inhibited by euflavine added 4 hr. after infection, though not by 5-fluorouracil added at this time. In the final stage of virus reproduction a core containing the nucleic acid and the hæmagglutinin are put together to make a virus particle. This phase can be disturbed by concentrations of euflavine which are too small to affect hæmagglutinin production. The ribonucleic acid component thus seems essentially to be a virus precursor. Besides its possible function as a centre for the later synthesis of hæmagglutinin, it may eventually become incorporated into the virus particle itself. The process of incorporation is not, however, 100 per cent efficient and a proportion of the component fails to get included in virus particles; it is this extra material which gives rise to the infective ribonucleic acid that can be extracted from the extracellular fluid at the end of virus growth.

It has been stated elsewhere[8] that infection of a cell by virus starts two processes—one resulting in the production of progeny virus, and the other in cell death. The train of events which leads to death of the cell seems to depend on some key change which takes place very early in the growth-cycle. Procedures which favour the production of virus containing anomalous nucleic acid, interfere with the synthesis of hæmagglutinin, or the assembly of virus particles, do not normally prevent cell destruction at the proper time. Blocking virus synthesis by adding 5 μgm./ml. euflavine within ½–1 hr. of infection preserves the cells from eventual destruction, which suggests that the irrevocable event which eventually leads to cell death may be the start of synthesis of the ribonucleic acid component itself. However, evidence from analysis of the interaction between encephalomyocarditis virus strains of narrow host-range, and ascites cells with which they are unable to form plaques, indicates that this may not be so. Cells of the Ehrlich carcinoma or sarcoma 37 are able to take up encephalomyocarditis virus of mouse brain origin[8,16], although new hæmagglutinin or plaque-forming virus is not produced as a result of infection. Large amounts of infective ribonucleic acid—as much as is produced by the fully susceptible Krebs 2 cells—can be extracted from such abortively infected Ehrlich or sarcoma 37 cells, and a component containing this ribonucleic acid is set free into the external medium. Such cells do not die as a result of infection, so death of a cell need not be an inevitable consequence of synthesis of viral ribonucleic acid.

FALL-OUT OVER NORWAY FROM HIGH-YIELD NUCLEAR EXPLOSIONS

By T. HVINDEN, D. HVEDING, A. LILLEGRAVEN and S. H. SMALL

Division of Physics, Norwegian Defence Research Establishment, Kjeller

FROM measurements made in Norway during the past three to four years it seems that fall-out materials which rise well into the stratosphere after high-yield test explosions begin to reach the lower stratosphere over south-east Norway shortly afterwards. The radioactivity in the lower stratosphere seems to increase to a peak about one to two months after the explosions and then to decrease with an effective half-life of about a month. This is shown in Fig. 1, curve *A*, the arrows indicating the delay times. The radioactivity of fall-out materials in air near the ground also begins to increase shortly after the explosions, but more slowly, and seems to reach a peak, which is considerably lower than the peak in the lower stratosphere, after about six to seven months. This is shown in Fig. 1, curve *B*, the delay times being once again indicated by arrows. The rate of increase apparently results in a doubling of the radioactivity in the course of a month or so. The subsequent rate of decrease appears to be the same as in the stratosphere, the radioactivity being halved about once every month. The radioactivity of fall-out materials in precipitation begins to increase at about the same time as the radioactivity of air near ground-level, and follows very much the same pattern. This is shown in Fig. 1, curve *C*.

An interesting observation from Fig. 1 is that the rates of decrease of radioactivity in the atmosphere after large additions of fall-out materials during the years 1957–59 have been remarkably alike, regardless of the overall amounts of fall-out materials in suspension. By correcting for radioactive decay, it can be calculated that the effective residence half-life of fall-out materials in the lower stratosphere over south-east Norway has been of the order of three months.

Since fall-out materials may begin to arrive in air near ground-level shortly after high-yield explosions, it follows that during periods when explosions occur at relatively short intervals there may be considerable mixing of materials near the ground. This can be illustrated by the position at the end of

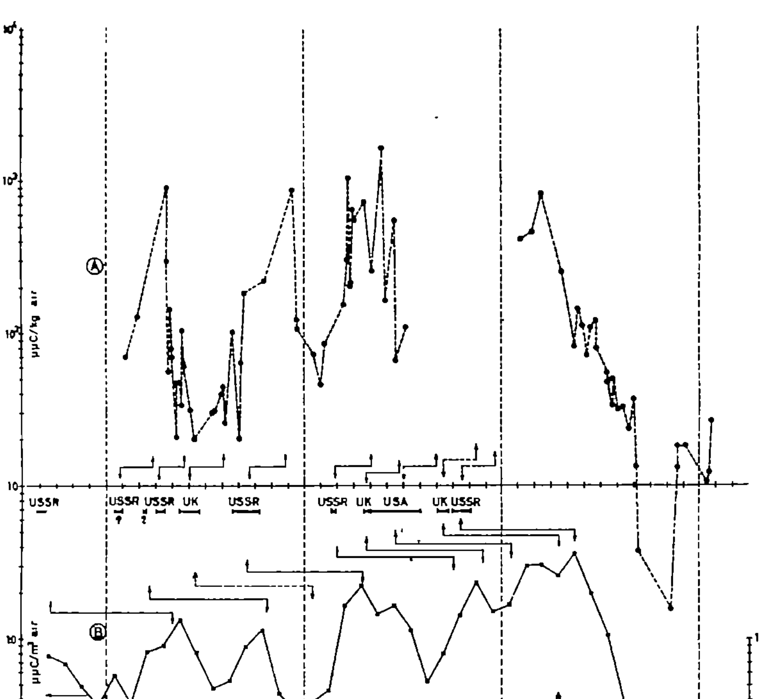

Fig. 1. Results of measurements of fall-out materials during the period September 1956–January 1960

Curve *A*, concentrations of fall-out materials in the lower stratosphere over south-east Norway. Each point represents the result of one measurement. Curve *B*, monthly average concentrations of fall-out materials in air near ground-level. Each point represents an average value of measurements from nine stations. Curve *C*, monthly average concentrations of fall-out materials in precipitation. Each point represents an average value of measurements from twelve stations

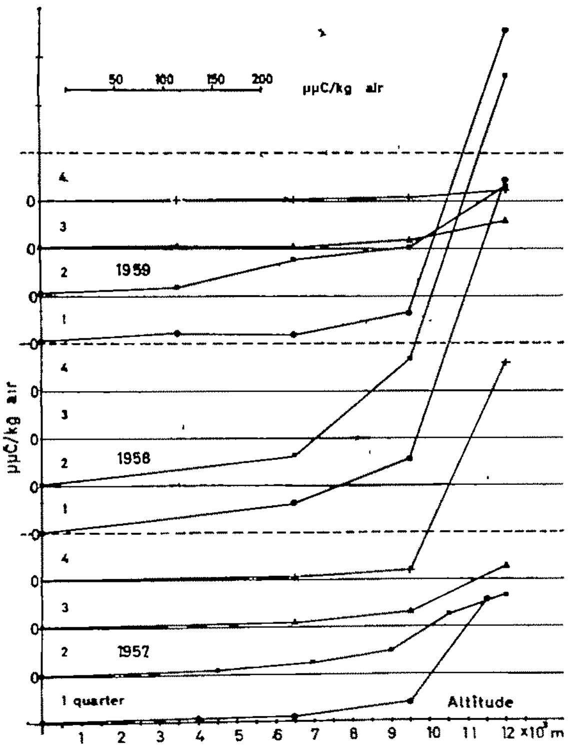

Fig. 2. Concentrations of fall-out materials at different heights above ground-level over south-east Norway during 1957–59. Most points represent the average of 5–10 measurements made during each quarter

1958, when materials from at least five test explosion series could have been present in significant quantities. It is therefore problematical whether isotope ratios or decay-rates can provide reliable information about the origins of fall-out materials at such times. There is no outstanding seasonal variation in Fig. 1 which cannot be explained by the 'seasonal variation' in test explosions.

It has been found that the concentrations of fall-out materials in precipitation depend to some extent upon amounts of precipitation, which vary very much. Consequently it is not to be expected that curves *B* and *C* of Fig. 1 should be completely alike. Nevertheless, there is a very obvious similarity between them, and it can be deduced that on the average 1 cm.^{3} of precipitation has contained about the same amount of fall-out materials as 1 m.^{3} of air near ground-level.

The curves shown in Fig. 2, which indicate the way in which concentrations of fall-out materials vary with height above sea-level, might at first sight be interpreted as indicating that downward transport of fall-out materials is hindered by the tropopause layer. However, it seems very possible that the marked increase in concentrations at about tropopause height is due to the rapid removal of materials from lower air layers. Fig. 2 would then indicate that removal processes are effective up to heights of several km. By comparing measurements of airborne materials with measurements of deposited materials, it has been calculated that it would have been necessary to remove the total content of fall-out materials in the troposphere over south-east Norway about once every month, in order to account for the measured deposition. This implies a rather rapid rate of supply to the troposphere, and is interesting in connexion with the short residence half-life of fall-out materials in the lower stratosphere deduced from Fig. 1.

Fig. 3 shows that the main variations in concentrations of fall-out materials in surface air occur approximately simultaneously at measurement sites from Vadsø in the north to Sola in the south, a distance of about 1,700 km. This is quite interesting because the sites are at different heights above sea-level, and are exposed to markedly different weather conditions. It seems clear from Fig. 3 that if fall-out materials are mainly removed from the stratosphere by downward air movements, then these must occur rather consistently over a wide region.

Although much more work must be done to find out what happens to fall-out materials after a nuclear explosion, it now seems that deposition is a fairly continuous short-term process, lasting months instead of years, and affecting very large areas. It is possible that fall-out particles may achieve significant settling-rates, particularly in the lower stratosphere and upper regions of the troposphere. Removal from the stratosphere by downward air movements would then be relatively less important than previously assumed.

In view of the short deposition times, measurements of external radiation-levels and gross activity

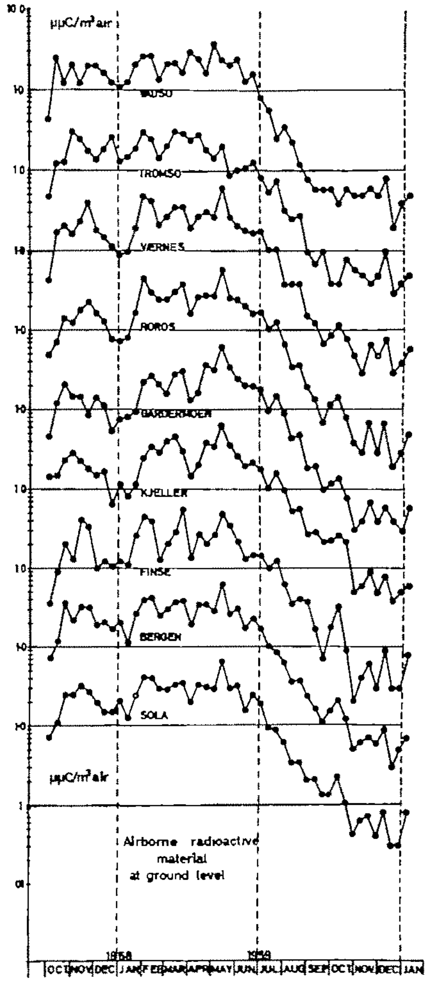

Fig. 3. Mean measurements over ten-day periods of concentrations of fall-out materials in air near ground-level at different stations in Norway during October 1958–January 1960

measurements now have an increased importance, in relation to measurements of selected long-lived isotopes, in assessing possible radiation hazards.

The investigations described in this article form part of a programme of fall-out measurements carried out by the Norwegian Defence Research Establishment. We wish to acknowledge the help given by the Royal Norwegian Air Force and the Norwegian Meteorological Service in collecting samples of fall-out materials, and by members of the Physics Division of the Norwegian Defence Research Establishment in measuring samples, etc.

RADIOACTIVE MATERIALS AND THE SKELETON

THE one-day conference organized by the Bone and Tooth Society on "Radioactive Materials and the Skeleton" included papers on tracer applications of bone-seeking isotopes in biology and in medicine, studies of their biological effects, measurements on rates of deposition of strontium-90 in fall-out, the entry of strontium-90 into food, a survey of the radiation doses received by man from environmental sources and some discussion on the biological implications of environmental radiation in so far as bone was concerned. It was, in fact, a very ambitious programme for a short meeting, but it served the very useful purpose of allowing this controversial subject to be seen as a whole.

The first paper, "Anatomical Sites of Deposition of Radioactive Materials in Bone", was given by Prof. P. Lacroix, of the University of Louvain, who has himself been responsible for many fundamental advances in the field of the dynamics of bone growth. He showed calcium-45 autoradiographs of bones of young and adult dogs and discussed the relevance of the variations in the uptake of calcium throughout the bone to our understanding of the various processes of bone growth and remodelling which take place. Of particular interest was the change in the pattern of uptake with age of the young animal. Soon after birth the major mode of transverse growth of the long bones is by the peripheral deposition of thick layers of bone, the structure of which is still undetermined. This, however, gives way to transverse growth mainly by a process of deposition of rows of osteones under the periosteum, with a different pattern of calcium uptake, which is clearly demonstrated by autoradiography.

In clinical work with bone-seeking isotopes the material for autoradiographic investigation is generally not available and the distribution of the administered isotope must often be determined by external counting methods, which give relatively poor resolution. Much less information is derived than from experimental biological studies but still, as the second paper of the conference, "Bone-seeking Isotopes as Indicators of Bone Turnover", by Drs. G. Bauer and Bo Wendeberg, of Malmö, showed, information can be obtained on the turnover of bone mineral in pathological conditions of bone which cannot be obtained by other methods.

A study of the metabolism of strontium, with strontium-85, in human subjects using two volunteers, was next described by Dr. G. E. Harrison, of the Medical Research Council Radiobiological Research Unit, Harwell, in his paper, "The Skeletal Retention of Radioactive Strontium in Man following an Intravenous Dose". Although a dose of only 0·5 μc. strontium-85 was given to each subject, it was possible to follow the retention pattern for one year, first using excretion data and then measurements on retained activity by whole-body counting. The results for the two subjects were remarkably similar, demonstrating the early initial excretion and then a period of relatively rapid loss with a half-life of about 50 days followed by a slow loss from the relatively unexchangeable part of bone. The calculated mean radiation dose to the skeleton over a period of 300 days was 0·23 rad.

The three papers of the second session dealt with the biological effects of bone-seeking radioactive isotopes. There is a considerable literature on this subject relating mainly to rates of tumour incidence with different isotopes. Large differences in tumour incidence have been found with different isotopes and different patterns of administration ; but the significance of such differences are obscure without information on the distribution of radiation dose in bone and its variation with time, and such information is generally not available.

The first two papers both discussed the histological changes in the bones of growing animals in relation to measured radiation dosage distribution. The first paper, "The Relation of Radiation Damage to Radiation Dose from Strontium-90", by Drs. Sheila Macpherson and Maureen Owen, of the Medical Research Council Group for Research on Bone-Seeking Isotopes, Oxford, dealt with the effect of a long-lived isotope in rabbits, whereas the second, "Bone Tumour Production : Dose Response Relationships using Phosphorus-32", by Drs. J. P. M. Bensted and N. M. Blackett, of the Physics Department, Institute of Cancer Research, London, discussed the effects of a relatively short-lived isotope in rats. In spite of these differences there was much similarity in the gross biological effects observed and both papers demonstrated the considerable reparative capacities of bone to large radiation doses, of the order of thousands or even tens of thousands of rads. With regard to possible histological antecedents of bone tumour production the two sets of experiments had less in common. Whereas with repeated doses of phosphorus-32, which is a particularly efficient method of producing bone tumours in the rat, an increase in connective tissue in the metaphysis appeared to be closely related to bone tumour production, the experiments with strontium-90 did not demonstrate this. In both sets of experiments the tumours observed arose after very heavy radiation doses, of the order of thousands of rads.

These two papers pointed to the work that remains to be done in this field, rather than to what has been achieved. Certainly the mechanisms of bone tumour production by radiation and the likelihood of bone tumours appearing at low dosage-levels are not yet subjects for easy speculation.

Abnormality in tooth development of young animals given large doses of bone-seeking isotopes is a common finding in experimental work, but relatively little work has been done on the histological changes involved. Prof. M. A. Rushton, of Guy's Hospital Medical School, in his paper, "Damage to Dental Tissues in High-Dose Rabbit Experiments", presented a detailed histological study of the response of the developing teeth of weanling rabbits given large doses of strontium-90 (600–1,000 μc./kgm.). The damage observed was very severe; but the radiation doses were extremely high, of the order of tens of thousands of rads. It is greatly to be hoped that work of this calibre can be extended to much lower levels of radiation dose.

The third session was devoted to problems of environmental radioactivity where the radiation dose-rates involved are of the order of a fraction of a rad a year. The first two papers presented dealt with the measurement, and some aspects of the metabolism, of strontium-90. In order to measure the amounts of strontium-90 deposited in Great Britain from fall-out and the resulting labelling of our foodstuffs a considerable organization has had to be built up, whereby samples can be collected from any parts of the country. In their paper, "Strontium-90 in the Environment and in Human Bone", Drs. F. J. Bryant and D. H. Pierson, of Atomic Energy Research Establishment, Harwell, described measurements of strontium-90 content in rain, in drinking water, in human bone and teeth. Apart from the number of test explosions made there are two main factors determining the rate of deposition of strontium-90. The first is the magnitude of the explosions. Debris from explosions of kiloton bombs does not penetrate the tropopause and has a mean residence time in the troposphere of about 30 days. The debris from megaton bombs is, however, injected into the stratosphere and the mean residence time may be as long as 10 years. The second determining factor is the total rainfall over the given period. The strontium-90 content in tap-waters derived from lakes in the United Kingdom in early 1959 was 0·9 μμc./l., with lower values for river waters and wells. The highest strontium-90 content of human bones was found in the age-group 0–5 years and had the average value in the femur of 0·83 μμc./gm. in the second half of 1958.

Dr. R. Scott Russell, of the Agricultural Research Council Radiobiology Laboratory, Wantage, in his paper, "Radioactive Materials in Foodstuffs", discussed the uptake of strontium-90 in plants and vegetation. He stressed that the major part of the strontium-90 contamination of our foodstuffs came from direct deposition of strontium-90 on to the plant rather than via the soil. It could also be shown that there was only a short interval, not more than about two months, between the deposition of strontium-90 and its appearance in milk, the major source of calcium in our diet in Great Britain. Consequently the strontium-90 content of our food was much more dependent on the rate of deposition of fall-out than on the total accumulated amount.

It must have been very clear from these two papers that the information so far obtained on the deposition of strontium-90 in fall-out and its progress through the food chain is the result of a concentration of highly skilled and intelligent effort and has, in the course of the work, opened up new lines of advance in many fields, from meteorology to agriculture. However, the object of the exercise was to learn something of the biological consequences of fall-out, and the measurement of levels of activity can represent only the preliminary step. The translation of these measured quantities into biological effect is the real challenge.

The values of radiation dose-rate in bone resulting from present levels of fall-out was included in the paper given by Prof. F. W. Spiers, of the University of Leeds, on "Radiation Doses to Bone from all Sources". He first dealt with the problem of where in bone one should measure the radiation dose. Clearly the choice must depend on the degree to which the various tissues comprising bone are significant in the development of late effects. This, however, is not known and the significant dosage values must therefore be uncertain, particularly for the alpha-emitting isotopes, on account of their short range. For strontium-90, with its relatively long beta range, there is still a problem, though not so severe as with the alpha emitters.

Prof. Spiers presented tables of the radiation doses received by bone and by soft tissue from cosmic rays and local gamma-rays, from the natural radioactivity of tissues, and from the strontium-90 and cæsium-137 originating in fall-out. Within Great Britain the total dose-rate received from all sources is of the order of 100 millirem per annum, and of this amount cosmic radiation and local environmental radioactivity contribute about 90 per cent. At present levels the strontium-90 contribution to bone does not normally exceed about 4 millirem a year. The contribution to gonadal tissue is extremely small. The major variation in environmental radiation dose received by an individual depends on the gamma-ray contribution from the local environment, but variation in the natural alpha activity of tissues also plays an appreciable part. As a result of these variations in natural radioactivity the dose-rate in bone may vary between individuals by a factor of as much as 2.

Radiation dosage data such as those presented by Prof. Spiers allow one to come to certain conclusions concerning the comparative somatic effects of the various components of environmental radiation. It is difficult, for example, to avoid the conclusion that if present levels of strontium-90 in bone constitute a hazard, a change in locality may incur a much greater hazard. Beyond such comparative statements it is difficult to go, since the biological data relevant to the late radiation changes in bone refer to radiation dose-levels several orders of magnitude higher than that of environmental radiation. Any theoretical treatment of the problem of the somatic effects of small doses involves the widest assumptions—on the part played by specific cell changes, on the significance of gross tissue damage, on the types of tissue at risk and on the part played by the normal homœostatic mechanisms of the body. Nor is it at all certain that a direct attack on the problem, by giving small doses of radiation to large numbers of experimental animals, is justified. In my paper, "The Biological Implications of Radiation Dosage to Bone from Environmental Radioactive Material", I suggested that too much preoccupation with the quantitative aspects of the late effects of low-level irradiation could, in the present state of knowledge, be a great waste of effort and even a hindrance to the better understanding of the subject. It would seem more reasonable to accept the fact of our present ignorance, to rely on comparative radiation dosage data for necessary action and to concentrate experimental effort on a study of the mechanisms, rather than the statistical aspects, of late radiation effects.

L. F. LAMERTON

OBITUARIES

Sir Ernest Barker, F.B.A.

THE death on February 17 of Sir Ernest Barker, at the age of eighty-five, means not only the loss of a great scholar and teacher but also the loss of a symbol of what may well seem, in 1960, to have been a happier and more confident world. Ernest Barker always denied being a 'scholar' in the old-fashioned Oxford and Cambridge classical sense. But all that that meant was that he was not one of the elaborately skilful composers in the ancient tongues whom Macaulay (who himself was a master of these dexterities) made fun of. Barker was a very distinguished product of the Oxford 'Greats' school. I suspect that he never lost his conviction, even after many happy years in Cambridge, that for the statesman and for the teacher of statesmen the school of *Literae Humaniores* was the ideal education.

It would be both absurd and unjust to suggest that Barker was an old-fashioned classic incapable of understanding or appreciating the contributions of more modern studies to the science (or as he would have preferred, I think, to put it) the art of politics. He preserved into his old age a great deal of curiosity about modern developments and modern contributions. But it would be also absurd to pretend that he was ever convinced that the modern American statistical analysts of political behaviour and, still more, the modern psychological explainers of political behaviour, have really improved on the study and explanation of the human situation provided by Plato, Aristotle, and St. Thomas Aquinas.

Barker wrote a great many books, all of them meritorious and some very remarkable. His essay on "The Crusades" for the "Encyclopædia Britannica", published as a little book, seems as remarkable to me now as it seemed when, as an undergraduate in Oxford, I had my attention directed to it by the late B. H. Sumner. In his old age he wrote what I am told was an extremely competent book on Byzantium. But I think that his greatest achievement was his "Political Thought of Plato and Aristotle"—a book full of learning and wisdom. I once reproached him for not producing a new edition and almost coaxed him into an admission that he had wasted a good deal of time on less-important things. He did, in fact, produce a new volume on Plato, but never finished the complete revision of this masterpiece. He spent (or, as I think, wasted) an immense amount of learning on a translation of Gierke, which involved the resuscitation of a great many rightfully forgotten Germans. 'C'était magnifique', but it was not what we wanted from Ernest Barker. I think he came to feel this, for he does not cite this laborious and learned and in some ways useful work in "Who's Who".

Barker was a Liberal (both upper case and lower case letters), and that comes out in the admirable little volume he wrote in the Home University Library on English political thought "From Herbert Spencer to To-day" and in his "Principles of Social and Political Theory". He would never have understood that it was possible to separate politics from morals, to reduce politics to statistical description. As much as Dr. Gunnar Myrdal, he would have held that the idea of ethically neutral means was nonsense. Politics was about ethics. If this were not true, it was not worth serious study.

Barker was not only a man of prodigious learning, he was also a man of prodigious energy. At an age when most people think of retirement as a reality, nearly ten years after he had ceased to be professor of political science in Cambridge, he went to Germany, out of a strong sense of mission, to rehabilitate the lost German tradition of academic freedom. It was a task that might have daunted a younger man, and he suffered a very serious illness from which, some think, he never quite recovered, although he continued to work with an energy that would have shamed many men much younger than he was.

In addition to immense intellectual and physical energy, Barker was extremely handsome and had a most magnificent voice, which was made even more effective as it preserved its northern burr. There is a tradition in Peterhouse that he imagined he had lost this burr. Fortunately there was no basis for this illusion. He not only had an academic career of great distinction, but also one of great variety. From Manchester Grammar School he went to Balliol and was successively Fellow of Merton, St. John's, and New College, where he had a most admiring pupil in the late Harold Laski. He was, for a short and not very happy time, principal of King's College, London, and then he was, for a very long and happy time, the first professor of political science in Cambridge and Fellow of Peterhouse. In contemplating Ernest Barker it was easy to think of him as a relic of a dead past. But it was much wiser to think of him as a representative of a great past, of the disciples of T. H. Green (and of Henry Sedgwick), of the moralistic and learned political philosophers of a great era of modern English history. He survived into what he must have thought—and did think—was an evil and distracted world. But he continued to be loyal to both his theory and practice. If sometimes he seemed unreceptive to new ideas, he was totally above the temptations of fashion or current academic prestige. "We shall not look upon his like again."

D. W. BROGAN

Dr. Hsien Wu

DR. HSIEN WU, an authority on blood analysis, died on August 8, 1959. He was born in Foochow, China, on November 24, 1893. He attended a local high school in Foochow and then enrolled in the naval architecture course at the Massachusetts Institute of Technology. After two years, he changed his course to chemistry and was awarded the B.S. degree by the Institute in 1916. After remaining as an assistant in the Department of Chemistry for a year at the Institute, he entered Harvard Medical School in 1917 for graduate study with Dr. Otto Folin in the Department of Biological Chemistry, and received the Ph.D. degree in June, 1919. He continued his researches as a Fellow with Dr. Folin for a further year.

In 1920, Dr. Wu returned to China as assistant in biochemistry at Peiping Union Medical College. After one year, he was raised to an associate and later placed in charge of the Department. In 1924, he was appointed an associate professor of biochemistry and in 1928 he was raised to professor and chairman of the Department of Biochemistry. He continued as chairman of the Department until January, 1942, when Japan took over the College. In March, 1944, he was called to Chungking to organize the Division of Nutrition and join the National Institute of Health. In July, 1944, the Chinese Government sent him to the United States as its nutrition expert on a special mission to study rehabilitation reconstruction programmes for post-war China. He served as director of the Nutrition Institute, Ministry of Health, until the end of 1947. He was also associated with the Institute as the director of its Peiping Branch during 1946–47.

In 1947, Dr. Wu and five other Chinese scientists were invited by Unesco to attend the International Physiological Congress which was held at Oxford. On his return from the Congress, by way of the United States, in September, 1947, he was extended the privileges of a visiting scholar in the Department of Biochemistry, College of Physicians and Surgeons, Columbia University. In June, 1948, he was appointed a research associate at Columbia. Sensing the political situation in China, he finally made preparations to move his family to the United States.

Dr. Wu joined the Department of Biochemistry, Medical College of Alabama, Birmingham, on September 1, 1949, as visiting professor. Following a heart attack in October, 1952, he retired on September 30 and moved to Boston, Massachusetts, where he devoted his time to higher mathematics, Spanish and writing.

Dr. Wu was a member of an Administrative Committee of three functioning as director of Peking Union Medical College, 1935–37. He was a member of the Chemistry Division of the National Committee on the Standardization of Scientific Terminology during 1921–27; he served as editor of the *Chinese Journal of Physiology*, 1926, and continued on the editorial board until 1942; and was president of the Chinese Physiological Society, 1931–34.

Dr. Wu was a tireless investigator. His bibliography has 160 entries, which includes two books: "Principles of Nutrition" (1929) and "Principles of Physical Biochemistry" (1934). His fields of research included blood chemistry, gas and electrolyte equilibria, nutrition, immunochemistry, proteins and the metabolism of amino-acids using amino-acids labelled with nitrogen-15 as tracer.

In addition to his contribution of the famous system of blood analysis he also was a pioneer in his researches and theory in other major areas. He made quantitative analyses of the precipitate from the antigen–antibody reaction following the use of labelled antigen. In 1928, he used hæmoglobin which was labelled with a coloured group. The next year, he reported the use of iodo-albumin as the antigen and he analysed the antigen precipitin precipitate for iodine and nitrogen content. These were the first analyses of this nature and antedated the use of isotopes for such analyses by several years. He also proposed the first reasonable theory of denaturation of proteins in 1931. Other valuable contributions to protein chemistry by Dr. Wu were his studies on the molecular weights and osmotic pressures of hæmoglobins of experimental animals in aqueous solution, 65 per cent glycerine solution and in concentrated urea. He noted that the molecular weights of oxyhæmoglobins and hæmoglobins of dog and sheep are not changed in urea solution whereas those of ox and horse are reduced to one-half.

EMMETT B. CARMICHAEL

NEWS and VIEWS

Pioneer 5

THE United States space probe *Pioneer* 5 was launched from Cape Canaveral in Florida at 13.00 U.T. on March 11, to become the third artificial planet of the Sun. The launching missile was a three-stage *Thor-Able* rocket, and the final-stage vehicle attained a velocity of about 6·9 miles per sec. relative to the Earth, in a direction nearly opposite to that of the Earth's motion around the Sun. Its residual velocity relative to the Sun, after escaping from the Earth's sphere of influence, was therefore less than the Earth's orbital speed, and its orbit is consequently smaller than that of the Earth: it is expected to be about 75 million miles from the Sun at perihelion, and about 92 million miles at aphelion, with a period of 311 days. At perihelion it will be near the orbit of Venus, which moves in a nearly circular path at a distance of 67 million miles from the Sun.

Pioneer 5, which weighs 90 lb., has a 5-watt radio transmitter for use near the Earth and a 150-watt transmitter for use at greater distances. The power is provided by solar batteries arranged in four 'paddle-wheel' vanes. To conserve energy, the transmitter is to be switched on for only a few minutes each day, in response to commands from Earth. The radiotelescope at Jodrell Bank is the main tracking station, and the 150-watt signals should be received at distances out to about 50 million miles. If so, *Pioneer* 5 will be within communication distance for about the next five months. *Pioneer* 5 carries various scientific instruments, including a high-energy radiation counter, an ionization chamber and Geiger counters to measure medium-energy radiation, a magnetometer to determine both the strength and direction of the magnetic field in space, and equipment for detecting micro-meteorites.

Pharmacology at University College, London: Prof. F. R. Winton

PROF. F. R. WINTON, who is retiring from the University of London chair of pharmacology at University College, was trained originally in chemistry and had been working for some time as an industrial chemist with the Mond Nickel Co. when he decided to take up medicine. He graduated M.D. (Cambridge) in 1926, and he obtained the D.Sc. (London) in 1942. After graduation, he worked with A. J. Clark in the Pharmacology Department of University College, London, and in 1931 returned to the Department of Physiology, Cambridge, first as lecturer and then as reader. In 1939 he was appointed to the London chair of pharmacology at University College, in succession to Prof. J. H. Gaddum. His earliest scientific work, carried out in conjunction with L. T. Hogben, dealt with the identification of a frog melanophore-expanding hormone in the pituitary gland. His subsequent scientific work was concerned mainly with two fields, the physiology and pharmacology of the kidney and of smooth muscle. His chief interest lay in the physical factors controlling the activities of the kidney and he succeeded in establishing and supporting experimentally a series of remarkably simple relations between arterial, venous, ureteric and glomerular pressures from which the capillary glomerular pressure of the mammalian kidney could be calculated. He also worked on the mode of action of diuretics, and during the War he was engaged in a study of the renal damage which followed crush injury in the limbs. Much of his renal work is summarized in a Harvey Lecture given in 1951. Winton's studies on smooth muscle reveal another aspect of his intense interest in the physical aspects of biological processes. They represent one of the earliest systematic studies of 'tonus' and contractility in invertebrate and smooth muscle. During the War, Winton was the only head of a department left in the Medical Faculty of University College and acted as dean throughout. The success of the evacuation of the Faculty to Leatherhead was in great measure due to his personality and drive. He has published several books, among which is the widely used "Text-book of Physiology", by Winton and Bayliss. Winton is a man of varied interests, a connoisseur of wine and a 'cellist of well above average amateur status. He has been throughout, together with his wife, the violinist, Bessie Rawlins, the main inspirer and one of the principal performers of the Chamber Music Club at University College. He has taken a major part in establishing the Student Health Service in the College.

Prof. H. O. Schild

H. O. Schild, who will succeed Prof. Winton, was born in Fiume. He studied medicine in Munich and began his career in pharmacology in Straub's laboratory. In 1932 he went to London to work with Sir Henry Dale at the National Institute for Medical Research. Later, he worked at the University of Edinburgh with I. de Burgh Daly and the late A. J. Clark. In 1937 he went to University College, London, to join Gaddum, with whom he had worked when he first came to England. He was appointed reader in 1947. Working with Gaddum, Schild found that adrenaline in high dilution, in contrast to noradrenaline, gave a strong green fluorescence in alkaline solution. This reaction, modified in various ways, is still the most sensitive physical method for the assay of adrenaline. Schild was the first to infer the presence in extracts of the suprarenal medulla of a second pressor substance, which we now know to be noradrenaline. He developed a method of demonstrating release of histamine in anaphylaxis by estimating the histamine diffusing out of small tissue particles suspended in Ringer solution on the addition of antigen. With this simple and ingenious method he showed with Hawkins and others for the first time that histamine is also released from lungs of asthmatic patients by the specific allergens. In collaboration with Mongar, he became interested in the intracellular reactions with lead to release of histamine. Schild observed that the anaphylactic and allergic contractions of smooth muscles cannot be fully accounted for by the release of histamine, since they occurred also in muscles rendered insensitive to it. We also owe to him the knowledge that strychnine and strychnine methiodide have the property of releasing histamine, one of the earliest demonstrations of histamine liberators; also the finding that inhibitors of diamine oxidase potentiate histamine just as anticholinesterases potentiate acetylcholine.

Pharmacologists value most perhaps his contributions to bioassay. He introduced statistically controlled methods for the assay of substances on isolated tissue preparations, whereby it became possible not only to obtain more accurate results but also to estimate the limit of error in each assay. They are used, for example, for the B.P. assay of oxytocin. He introduced a method for quantitative measurement of the activity of oxytocic drugs on the post-partum uterus in women. In order to ensure greater accuracy when assaying substances on smooth muscles, he designed an automatic method which is widely used. His approach to the study of drug antagonism has been particularly fruitful. It is the *pAx* method by which drug antagonism can be expressed quantitatively and agonists classified by means of antagonists. Drugs which act on the same receptors give the same *pAx* value with antagonists. Recently, he made the intriguing observation that drugs contract the fully depolarized smooth muscle, thereby excluding membrane depolarization as the only cause of contraction.

Meteorological Department of India:

Shri S. Basu

Shri Basu retired from the Indian Meteorological Service on February 23 after thirty-two years of service in that Department. He was born in the United Provinces on October 23, 1903, where he spent his early years and had a brilliant educational career. He completed his university career at Allahabad under the guidance of the late Prof. Meghnad Saha, whose personality profoundly influenced him as a young student. After completing his post-graduation in physics, Shri Basu entered the Meteorological Department of India in 1927, where he served until his retirement last month. During the period he was director-general of observatories, the Meteorological Department made notable advances in many directions. Apart from his activities in meteorological spheres, he actively participated in some of the other scientific organizations in India; he is a Fellow of the National Institute of Sciences in India and has been the secretary of it during the past four years. He is also a Fellow of the National Academy of Sciences, Indian Physical Society and a member of the Aeronautical Society. He is also the president of the Association of Indian Geographers. He was the founder-president of the Indian Meteorological Society and is now one of the vice-presidents.

In 1951 he was elected vice-president of the Commission for Climatology of the World Meteorological Organization. As representative of India, he led the Indian delegation at the meeting of the World Meteorological Organization in 1955 and 1959 at Geneva. He was a member of the Executive Committee of the World Meteorological Organization during 1954–59. As president of the Regional Association II of the World Meteorological Organization for Asia (1954–59), Shri Basu did a great deal of preliminary work the influence of which will serve to guide the affairs of the Association for many years to come. He has also been India's member in the International Civil Aviation Organization and of the Special Committee of the International Union of Geodesy and Geophysics for the International Geophysical Year.

Shri P. R. Krishna Rao

SHRI P. R. KRISHNA RAO succeeds Shri S. Basu as the director general of observatories, Government of India. He has had long experience of work in the department, having entered the service thirty-three years ago. He has had experience of international meteorological conferences since 1946, when he attended the first International Meteorological Organization Conference of Directors held in London after the Second World War. He recently led the Indian delegation to the joint session of the Meteorological Division of the International Civil Aviation Organization and the Commission for Aeronautical Meteorology of the World Meteorological Organization held in Montreal, and later paid short visits to the Canadian and United States Meteorological Services at Toronto and Washington.

Botany at Belfast : Prof. D. J. Carr

DR. D. J. CARR has been appointed professor of botany in the Queen's University of Belfast in succession to Prof. J. Heslop Harrison, who has been appointed professor of botany in the University of Birmingham (*Nature*, 173, 150; 1954). Prof. Carr was educated at the University of Manchester after war service with the Royal Air Force. In 1949 he became an assistant lecturer at Manchester, and after a year at the Max Planck Institute at Tübingen, working in association with Dr. G. Melchers, he was appointed a senior lecturer in the University of Melbourne. His promotion to a readership at Melbourne followed in 1959. While at Manchester and Tübingen, Carr was engaged in work on developmental physiology, especially in relation to the photoperiodic responses of flowering plants. Among his contributions in the field of photoperiodism was a demonstration, using grafting techniques, that leaves cannot be photoperiodically induced unless they are in organic connexion with a shoot apex, a result interpreted as favouring Gregory's hypothesis of photoperiodic induction, according to which there can be no accumulation of a 'flowering hormone' in leaf tissues. In Australia, Carr's interests have ranged widely, penetrating into the fields of ecology and taxonomy. He has added to the Australian bryophyte flora a remarkable member of the Marchantiales, *Monocarpus sphaerocarpus* D. J. Carr, a plant of saline flats in north-western Victoria. In association with his wife, Dr. S. G. M. Carr, he has recently begun a major study of the developmental morphology of the inflorescence and flowers of the important genus *Eucalyptus*.

Commonwealth Assistance in Training Teachers

IN a written answer in the House of Commons on February 24, the Secretary of State for Commonwealth Relations, Mr. C. J. M. Alport, said that good progress was being made in carrying out the proposals for assistance in training teachers put forward by the United Kingdom at the Commonwealth Education Conference. By the beginning of the next academic year it was expected that more than four hundred additional Commonwealth students would be coming to the United Kingdom to take courses in teacher training institutions with bursaries provided by the United Kingdom Government covering their tuition fees and full maintenance. This was more than half the existing total of Commonwealth teachers already receiving training in Britain. Places would be available for these students in a wide variety of training courses at institutions throughout the United Kingdom, and arrangements for their reception and welfare would be made by the British Council.

Mathematics and Science Teachers in Great Britain

IN a written reply to a question in the House of Commons on February 25 regarding mathematics and science teachers, Sir David Eccles said that in 1959 there were 5,100 mathematics and 7,700 science graduates teaching senior pupils in maintained schools, as well as 3,250 non-graduate specialists in these subjects in schools with courses leading to the General Certificate of Education at Ordinary level. Inquiry in 1958 revealed 244 vacancies in these schools for mathematics teachers and 261 for science teachers. Assuming an annual net increase of 500 mathematics and science graduates, the shortage of these teachers on 1959 staffing standards would be 500 in 1961, 750 in 1962, 900 in 1963 and 350 in 1964. In 1965, 250 would be available to improve on 1959 standards. The actual shortage would depend on the results of present measures to increase the number of graduates and the output of specialists from training colleges.

Laboratory Accommodation in British Schools

IN reply to a question in the House of Commons on February 11, the Minister of Education, Sir David Eccles, said that about £5 million would be spent in the 1960–61 and 1961–62 major building programmes to improve laboratory accommodation in existing schools; in addition, new schools had the full range of science facilities. He said he regarded this provision as one of the most important elements in the building programme, and in the maintained schools we were building, and would continue to build, every year at a higher rate than ever was spent on the public schools.

The Library Service in Great Britain

REPLYING in the House of Commons on February 11 to a question regarding the introduction of legislation to implement the recommendations of the Roberts Committee on the Public Library Service, the Minister of Education said that the Government accepted the need for legislation in this field, and he hoped shortly to begin discussions with associations of local authorities on his proposals. He thought it wise to obtain the views of local authorities before the subject was discussed in the House, and agreed that it was necessary to take into account the view that no good local authority that is running a virile library service should be deprived by its size of the right of continuing to do so. Sir David Eccles undertook to bring into his discussions the Smaller Library Group of the Library Association. He indicated that his proposals were more in the sense of retaining the power, authority and responsibility of smaller local authorities, and not transferring all these responsibilities to county councils, and that the library service essentially should be decided by local authorities and not subject to national standards other than the proposals of the report. He also agreed that account must be taken of the possibility of changes in the structure of local government resulting from the recommendations of the Commissions now operating before making any alteration in the library service and that the problem was highly controversial.

Fortieth Anniversary of the Liebig Museum

The Liebig Museum, Geissen, celebrates this year its fortieth anniversary. Although the Museum was not inaugurated until 1920, the idea had long been in the minds of German scientists and, but for the intervention of the First World War, would have most probably materialized many years before. It was decided at the beginning of the present century to set up as a memorial the Laboratory which Justus Liebig had made so famous. In 1909 a committee was formed for this purpose, including such scientists as Prof. Volhard, who at the time was the last living assistant of Liebig, Prof. Sommer, Prof. Behagel, Dr. Merck and many others. It was from this committee that the Liebig Association emerged in 1911. Much of Liebig's original equipment was transferred from the new Institute to the original Laboratory which he had persuaded the Darmstadt government to provide at Geissen in the early nineteenth century. Repair work was carried out on the Laboratory and much of the lost equipment was copied on the strength of drawings which had been found. The First World War delayed the opening until March 26, 1920; but such was its fate that only twenty years later it suffered further damage by yet another World War. However, after thorough reconstruction, for which funds could only be raised by collections, the Museum was reopened during the summer of 1952; the Institute which had proved to be the mother of chemical institutes all over the world was once more established.

U.S. Federal Funds for Science

The eighth issue by the National Science Foundation of Federal Funds for Science, dealing with the Federal Research and Development budget for 1958, 1959 and 1960, estimates Federal expenditure on scientific research and development for 1960 at 8,100 million dollars, an increase of 3 per cent over 1959, and compared with a 34 per cent increase in 1959 (pp. iii+74. NSF-59-40. Washington, D.C.: Government Printing Office, 1959. 65 cents). In 1959 the Department of Defence, the Atomic Energy Commission and the National Aeronautics and Space Administration accounted for 6,700 million dollars out of the 7,200 million for research and development. Of the remainder, 244 million dollars was expended by the Department of Health, Education and Welfare, 119 million dollars by the Department of Agriculture, 62 million dollars by the Department of the Interior and 57 million dollars by the National Science Foundation. Profit organizations were responsible for 65 per cent of Federal expenditure on research and development, Federal organizations for 24 per cent, and educational institutions for 9 per cent. Of the estimated expenditure of 1,444 million dollars on research in 1959, 964 million dollars was for the physical sciences, 432 million dollars for the biological, medical and agricultural sciences, and 48 million dollars for the social sciences. Fundamental research accounted for an estimated 488 million dollars in 1959 compared with an actual 331 million dollars in 1958 and an estimated 494 million dollars in 1960; of this, 335 million dollars were for the physical sciences, 142 million dollars for the biological sciences, and 11 million dollars for the social sciences; 49 per cent of the total was expended through educational institutions, 5 per cent through profit organizations and 37 per cent through Federal organizations. Expenditure on research and development plant increased from an actual 342 million dollars in 1958 to an estimated 662 million dollars in 1959 and 447 million dollars in 1960. Of the latter figure, 136 million dollars in 1959 and 92 million dollars in 1962 were on non-Federal sites, and 531 and 355 million dollars, respectively, on Federal sites. Since 1951, basic research, as a proportion of total research, has increased from about one-fourth to almost one-third. In the same period, expenditure on the biological sciences increased by 118 per cent, on the physical sciences by 56 per cent, and on the social sciences by 60 per cent.

Funds for Research in the United States

Data now available from the U.S. National Science Foundation's continuing survey of funds for research and development in the United States indicate an increase in those funds from just over 5,000 million dollars in 1953–54 to 12,000 million dollars in 1959–60, due primarily to an increase of about 160 per cent in the funds used for research and development by private firms and certain types of related organization which constitute the "industry sector" of the Foundation's programme: for industry the rise is expected to be 3,600 million dollars to 9,400 million dollars, more than half of which now comes from the Federal Government. For colleges and universities the corresponding increase is 126 per cent (450 million dollars to 1,000 million dollars), and for other non-profit institutions, 140 per cent (100 million dollars to 250 million dollars). Taking the completed year 1957–58 in comparison with 1953–54, funds for research and development increased from 5,150 million dollars to 10,050 million dollars, and of these Federal Government agencies provided 6,130 million dollars, compared with 2,740 million dollars; for industry the corresponding figures are 3,660 million dollars and 2,240 million dollars; for colleges and universities, 180 million dollars and 130 million dollars; and for other non-profit institutions, 80 million dollars and 40 million dollars. In terms of performance it is estimated that industry was responsible for 76 per cent of research and development in 1956–57 compared with 70 per cent in 1953–54; Federal Government agencies for 15 per cent, compared with 19 per cent; colleges and universities for 7 per cent, compared with 9 per cent; and other non-profit institutions were still responsible for 2 per cent.

The Metallurgist

By the issue of the first number of *The Metallurgist*, the Institution of Metallurgists has at last a publication worthy of its growing size and importance (*The Metallurgist*, 1, No. 1; January 1960. Incorporating the *Bulletin of the Institution of Metallurgists*. Pp. 64. Annual subscription, 63*s*. post paid). It is no function of the Institution to duplicate the journals of the other metallurgical institutes, and the contents of this issue are, therefore, concerned either with matters of domestic importance or with articles of general appeal. Among the former may be included the Institution's revised examination requirements, a most carefully carried out piece of work, and reports on the results of the examinations in 1959 and on national certificate results for which it is responsible. The articles comprise Prof. A. J. Murphy's presidential address, "Some Recollections" by Dr. Harold Moore, the first president, and a most interesting article by Prof. R. W. K. Honeycombe entitled "New Horizons in

Metallography", which discusses the applications of the electron microscope and of electron-probe micro-analysis. Dr. Howard K. Warner contributes an account of metallurgy in Australia which will be of great value to any member who contemplates taking up an appointment, teaching or industrial, in that continent. The presentation of the journal is most attractive and the illustrations excellently reproduced, the whole being a credit both to the Institution itself and all those responsible for its appearance.

Science in the School Library

A NEW edition of "Science Books for a School Library" has been published by John Murray for the Science Masters' Association (1959. 3*s.* 6*d.* net). It contains in its 54 pages three large sections on biology, chemistry and physics, of about 150, 100 and 100 titles, respectively, and smaller lists, on the history of science, astronomy, geology and meteorology. The final section is a list of books suitable for a secondary modern school science library. About half the entries have been reviewed in *The School Science Review*, and the number of the issue is given. Annotations are attempted in a rather half-hearted way, and the need for brevity is no excuse for "a readable book", "a well written history", "a most interesting book", or "packed with information". One wonders why J. B. Conant's "On Understanding Science" is in the chemistry section and hopes that all schools are able to afford Singer's "A History of Technology" (5 vols., £42). The list will be of great use to new schools setting up a library for the first time, or as a check list for an established library. Both users and the editors of the next edition would find of great interest two similar works—"The A.A.A.S. Science Book List" (American Association for the Advancement of Science, 1959) and the National Book League's "Science for All".

Tunnel Diodes

IN a recent press release, Standard Telephones and Cables, Ltd., announced the development of a new semiconductor device known as a tunnel diode, believed to be the first of its kind produced in Europe. The main feature of tunnel diodes is that they exhibit a marked negative resistance characteristic, which is likely to have important applications in radio circuit technique. The fact that a germanium diode made of very highly doped material can exhibit a negative resistance for a small applied voltage (100–200 mV.) was first reported by L. Esaki (*Phys. Rev*, 109, 603; 1958). The results of a theoretical and experimental examination of tunnel diodes as devices for use at very high frequencies were described by H. S. Sommers, of the R.C.A. Research Laboratories, Princeton, U.S.A. (*Proc. Inst. Radio Eng.*, 47, 1201; 1959). Diodes with a negative conductance of 1 mho have been made and these oscillate at frequencies above 1 kMc./sec. when incorporated in a special microstrip mounting of low series impedance. Apart from its use as a self-excited oscillator, the tunnel diode, when mounted in a coaxial or microstrip line, can be used as a switch with an operating period of a few milli-micro-seconds. It is believed that a different approach to electronic circuit problems is necessary in order to exploit fully the application of these tunnel diodes; and it is with the object of assisting circuit design engineers to gain experience of these that samples suitable for use at frequencies up to about 5 Mc./s. are being made available in Great Britain by Standard Telephones and Cables, Ltd. Development work is proceeding rapidly, however, and it is expected that devices with a more advanced performance will shortly become available.

High-atmosphere Research in the Meteorological Office

THE importance of the continuous study of conditions in the highest parts of the undissociated atmosphere (between about 30 and 100 km.) is now recognized among meteorologists. To further such studies, the Meteorological Office has set up a new assistant-directorate, with responsibilities for both theoretical and experimental research. It is intended to investigate the composition and physical state of the atmosphere up to about 100 km. with special balloons and, it is hoped, small rockets. In addition, the new unit will take over the present design studies for meteorological observations from the second *Scout* satellite. Dr. R. Frith, formerly assistant-director in charge of research in atmospheric physics, has been placed in charge of the unit.

James Clayton Prize, 1959

THE James Clayton Prize for 1959 has been awarded to C. Bernard Dicksee, for his pioneering and subsequent development and research work on the high-speed compression-ignition engine, and Prof. G. Fernie Mucklow, for continuous research and experimental work into the propagation of pulses (wave action) in gases, and problems connected with the internal combustion engine. This Prize is awarded annually to a member or members of the Institution of Mechanical Engineers, who contribute most in the year to modern engineering science by way of research, invention, experimental work or a treatise or paper on a modern engineering subject, or originality in engineering design, or by service to engineering.

The Corday-Morgan Medal and Prize

PROF. C. KEMBALL, professor of physical and inorganic chemistry, the Queen's University of Belfast, has been awarded the Corday-Morgan Medal and Prize for 1958 of the Chemical Society, in consideration of his contributions to the study of heterogeneous catalytic reactions. The award, consisting of a Silver Medal and a prize of 200 guineas, is made annually to the chemist of either sex and of British nationality who has published during the year in question the most meritorious contribution to experimental chemistry, and who has not, at the date of publication, attained the age of thirty-six years. Applications in respect of the award for 1959 must be received by the General Secretary of the Chemical Society, Burlington House, Piccadilly, London, W.1, not later than December 31, 1960, and for the award for 1960 before the end of 1961.

Nature Conservation: Postgraduate Diploma Course

THE social, economic and political problems arising from the results of a shortsighted policy for land use have been painfully obvious for a long time. Practical object lessons on a vast scale can still be seen in many parts of the world. Conservation involves the long-term study of land use, and one of the main problems is the prediction of the immediate and ultimate effects of any programme of agriculture or resource exploitation. The solution to these problems will provide the means for avoiding the disasters of the past. One of the main difficulties has been the lack of trained men, and to meet this need a postgraduate diploma course in conservation will be inaugurated at University College, London, in July. The course will consist of an initial period of field work, extensive and exploratory in nature, followed by two terms of indoor teaching and finishing with a second period of more intensive field work. The course will be run by the Botany Department, in collaboration with Geography and Zoology Departments of University College, with assistance from other departments and a wide range of seminars. The syllabus will include the physical factors of the environment, plant and animal ecology, and a study of different forms of land use and their effect on soils, plants and animals. This fundamental grounding should be applicable to conservation problems in different parts of the world. The Nature Conservancy will award maintenance grants for students to attend the course and will assist in other ways, especially with field work. The diploma will be a useful qualification to those seeking jobs with the Nature Conservancy, or similar organizations in other countries, or with the Colonial Service, or in any other aspect of applied ecology or land use.

Summer School in Radiation Protection

A fortnight's summer school of health physics (radiation protection) will be held at the Imperial College of Science and Technology, London, starting on July 4. The course will offer training in radiation protection, at postgraduate-level, for persons who are directly concerned with the subject, and should be of interest to safety officers, medical officers of health, factory inspectors and others concerned with radiation protection. The emphasis will be on practical applications, and training in the measurement of radioactivity will be included. Further information can be obtained from the Registrar, Imperial College of Science and Technology, South Kensington, London, S.W.7.

Royal Society of Tasmania

The following officers of the Royal Society of Tasmania for the year 1960 have been announced: *President*, His Excellency the Governor of Tasmania, the Right Honourable Lord Rowallan; *Vice-Presidents*, Dr. D. Martin and Mr. R .M. H. Garvie; *Council Members*, Mr. D. H. Borchardt, Dr. C. Craig, Mr. W. F. Ellis, Dr. E. R. Guiler, Mr. L. W. Miller, Mr. K. D. Nicolls, Mr. M. S. R. Sharland and Mr. J. W. C. Wyett; *Hon. Secretary and Librarian*, Dr. W. Bryden; *Hon. Treasurer*, Mr. G. E. A. Hale; *Hon. Auditor*, Mr. A. M. D. Hewer.

The Night Sky in April

Full moon occurs on April 11d. 20h. 28m. U.T., and new moon on April 25d. 21h. 45m. The following conjunctions with the Moon take place: April 1d. 08h., Aldebaran 0·4° S.; April 16d. 19h., Jupiter 5° S.; April 17d. 21h., Saturn 4° S.; April 22d. 01h., Mars 2° S.; April 24d. 01h., Mercury 1° S.; April 28d. 16h., Aldebaran 0·5° S. Mercury, Venus and Mars are too close to the Sun for easy observation. Jupiter is a morning star, rising at 1h. 40m., 0h. 50m. and 23h. 45m. on April 1, 15 and 30, respectively. It is moving eastwards in Sagittarius until April 20, on which date it is stationary; afterwards it begins to move westwards among the stars. Its stellar magnitude is − 1·9 and its distance from the Earth in the middle of the month is 450 million miles. Saturn is also a morning star, moving eastwards in Sagittarius until April 27, when it is stationary and commences to move westwards among the stars. It rises at 2h. 35m., 1h. 40m. and 0h. 45m. on April 1, 15 and 30, respectively. Its stellar magnitude is + 0·7 and its distance from the Earth on April 15 is 910 million miles. Occultations of stars brighter than magnitude 6 are as follows, observations being made at Greenwich: April 6d. 01h. 00·8m., 29 Cnc. (*D*); April 28d. 15h. 44·0m., Aldebaran (*D*); April 28d. 17h. 03·0m., Aldebaran (*R*); *D* and *R* refer to disappearance and reappearance, respectively. The Lyrid meteors are active during April 20–22; the radiant is at R.A. 18h. 04m., Dec. + 33°, and conditions for observation are fairly favourable.

Announcements

Mr. S. S. Kind has been appointed editor of the newly founded *Journal of the Forensic Science Society*. Communications should be addressed to the Editorial Office, c/o Rossett Holt, Pannal Ash Road, Harrogate, Yorks.

The Bureau of American Ethnology of the Smithsonian Institution has announced recently (Bulletin No. 130) completion of the long awaited index to the volumes entitled "Handbook of South American Indians". The index appears in Vol. 7 (Washington, D.C.: Government Printing Office, 1959).

Following an investigation into technical readership by the Department of Scientific and Industrial Research, Heywood and Co., Ltd., are to establish *Electronics Weekly* in September. It will appear as a newspaper and will be directed at manufacturer and user, as well as to management and scientific staff. Further information can be obtained from Heywood and Co., Ltd., Drury House, Russell Street, London, W.C.2.

A symposium on the Matrix will be held by the Bone and Tooth Society at the Nuffield Department of Orthopædic Surgery, University of Oxford, on March 29. Further information can be obtained from B. Cohen, Royal College of Surgeons, London, W.C.2.

The spring meeting of the Parasitology Group of the Institute of Biology is to be held at the Liverpool School of Tropical Medicine, Pembroke Place, Liverpool 3, during April 6–8. Further information can be obtained from L. P. Joyner, Ministry of Agriculture, Fisheries and Food, Central Veterinary Laboratory, New Haw, Weybridge, Surrey.

An informal discussion by the Colloid and Biophysics Committee of the Faraday Society on Cytoplasmic Particles and their Role in Protein Synthesis will be held in the University of Reading during March 28–29. Further information can be obtained from Prof. J. A. V. Butler, Chester Beatty Research Institute, Fulham Road, London, S.W.3.

The Campaign for Nuclear Disarmament announces the formation of a Scientists Group, the purpose of which is to advise the Campaign, in the light of available scientific information, on such subjects as fall-out, civil defence, control of tests, effects of nuclear war, relevant aspects of general disarmament, and civilian uses of nuclear energy. The Group is publishing a regular bulletin, of which the first number (4 pp.) has recently appeared; it includes a number of abstracts of recent scientific papers and publications dealing with fall-out and related topics. Further information can be obtained from the Secretary, Campaign for Nuclear Disarmament, 2 Carthusian Street, London, E.C.1.

UNIVERSITY EDUCATION IN CENTRAL AFRICA

THE events which led up to the granting of a Royal Charter to the University College of Rhodesia and Nyasaland on February 11, 1955, have been reviewed in *Nature* (172, 1; 1953. 173, 107; 1954. 175, 181; 1955). Now, five years after its establishment, the first results of degree examinations in the College have been announced, and it is opportune to review the five years of life of this flourishing multi-racial establishment. A basic principle in the foundation and planning of the University College was that there should be no discrimination in it on racial grounds, and, as was said in 1955 (*Nature*, 175, 181; 1955), "In a country where racial tension can arise, the position of a multi-racial University is especially important". The agreement of Her Majesty Queen Elizabeth the Queen Mother to become the first President of the College, and her presence at Salisbury when she was formally installed on July 5, 1957, were particularly happy auguries for the development of this young university institution. As President of the College she will preside at the degree ceremony on May 13, 1960, in Salisbury.

The first academic session opened in March 1957 with a total of 74 students, 8 of whom were African (*Nature*, 179, 612; 1957). During the session that has just closed there were 168 students, of whom 38 were African. The proportion of African students in the College is steadily rising, and, with the development of sixth-form school education throughout the Federation of Rhodesia and Nyasaland, may be expected to rise still further.

The University College is in special relationship with the University of London and the students therefore now take the degree examinations of that University. At the end of the session which has just closed 19 candidates sat for the B.A. General degree, of whom 17 were successful, one being placed in the first division. Six candidates out of the seven who sat for the B.Sc. General examination, and both of two candidates who took that for B.Sc. Agriculture, were successful in obtaining degrees. In addition, 23 out of 26 candidates successfully completed the course and examination for the postgraduate certificate in education. Of the total number of successful candidates, nine were African.

The examination results to date are a useful index of the soundness of the academic progress of the College. Nevertheless, the needed growth in breadth and depth of educational facilities still depends upon financial encouragement, and it is with great satisfaction that the news has recently been received of an offer of a grant of £250,000 by the Nuffield Foundation towards the establishment of a Medical School at the College. Training in medicine is extremely expensive, and it was natural that the institution of a Medical School should be delayed until a number of other faculties had been established, although this ultimate development was contemplated from the start.

The generous offer from the Nuffield Foundation is made on the understanding that the teaching hospital for the Medical School takes the form of a new multi-racial hospital on the site of the University College. The University of Birmingham and the University College of Rhodesia and Nyasaland have agreed that when a Medical School is established at Salisbury it shall initially be an affiliated institution of the University of Birmingham. This means that, for the period of affiliation, the students of the Medical School of the University College will be prepared for the degrees in medicine of the University of Birmingham just as those in the Faculties of Arts and Science at present prepare for the degrees of the University of London.

As so often seems to hold for university institutions, the financial support of the University College is scarcely adequate for all that, on other grounds, it might hope to do. Her Majesty's Government, which in the past has provided capital money totalling £1,475,000, has recently made a further generous grant of £1,400,000 towards capital costs for the College. The Government of the Federation of Rhodesia and Nyasaland has provided £750,000 over the first five years, for recurrent expenditure, and one may hope that it will give further generous support during the new quinquennium to help to provide for the cost of the much needed expansion which is already planned. At present, besides medicine, the College lacks only engineering and theology among the major faculties to be expected in a university institution.

The working out of a plan for racial partnership in all its details vitally depends upon the co-operation of educated people of all kinds. The significance of education, and particularly the higher education of Africans, in the working out of such a plan must be clear to all.

F. G. YOUNG

ADMINISTRATION OF UNIVERSITIES

THE chuckles in academic circles when Prof. C. Northcote Parkinson presented his famous law to explain certain empire-building propensities of industrial leaders may now be echoed by chortles from industrial leaders who read an article by Parkinson which deals with related matters in universities (*The Universities Review*, 32, No. 1; October 1959).

Although British universities do not yet boast the organizational luxuriance of American universities—the University of Pittsburg has a chancellor, three vice-chancellors, three assistant chancellors and sixteen directors, eighteen deans and a host of other executives—Parkinson asks whether British universities are not proceeding in the same direction.

A recent study of the expenditure of some fifteen British universities shows that the percentage of their allocation to 'administration' varies between 5 and 10·6 per cent of their annual budget, Bristol spending the least and Exeter bracketed with

Leicester in spending the most. The average is about 7·2 per cent—a not manifestly exorbitant proportion. Expenditure between universities is not an easy comparison to make, for much depends upon the detailed layout of the estimates. Nevertheless, the universities which spend more than 10 per cent might learn something from those which spend only 5 per cent. What these figures do not reveal is the extent to which academic time and effort are diverted to administration on a part-time basis. This is a field in which statistical comparison is more difficult. All that is gathered is a vague impression of middle-aged scholars bewailing the administrative work thrust upon them; a complaint sometimes intended to excuse their lack of literary or scientific output. Eagerness for office is due to several causes, among which the most important is the least noticed. Presiding over a committee or dictating a routine correspondence is far easier than doing a good piece of research. It may often be better paid and frequently leads to the higher offices and honours, so that the scholar is offered every inducement to desert the library and take to the filing cabinets. Part of the trouble with British university administration centres on this inducement. For those most easily tempted along the easier path are not necessarily the most competent, though many of them prove to be so. In some instances, the burdens of which they complain have become burdensome as a direct result of their own inefficiency.

Those who admire the system of some larger American universities would wish to give more extensive powers to the executive head. There is no assurance, however, that this would be either an improvement or an economy. What is needed is an equivalent of the army 'p.s.c.', a higher qualification to be obtained by a short course and accompanied by an impartial and secret assessment. "Could not some university organize a staff course in higher administration, to be supervised by retired vice-chancellors and held at some centre for research which could be furnished with all the information available about all the universities of the world?" The course would be held in the vacation and designed for those who had been in charge of departments and for whom higher responsibilities might be predicted. After some experience of the course, universities might limit their higher offices to those who had gained this qualification.

For a scheme of this sort one strong argument from army experience is worth noting. Such faults as were apparent in the British generals of the Second World War were seldom or never attributed to lack of brains. There were failures in leadership; but the staff college system prevented any repetition of Balaclava. The same cannot be said of the university world. Such a staff college would provide a ready-made group of advisers to which a university might turn for guidance.

There are some arguments on the other side. Some of these will derive from that strange reluctance which academic persons reveal when invited to apply scientific method to university affairs. There is no insoluble problem in academic administration so long as the university is kept down to a reasonable size. But there are problems which remain unsolved merely because those immediately concerned lack the ability to find a solution and because they fail to apply the sort of method which they would apply without hesitation to matters more obviously scientific. In this matter of using a methodical approach to a political problem, the universities have not only a duty to themselves but also a further duty, by way of example, to the world.

THE NUFFIELD FOUNDATION

THE fourteenth annual report of the Nuffield Foundation (pp. xii+201. London: The Nuffield Foundation, 1959), covering the year ended March 31, 1959, records for the first time expenditure on grants exceeding £1 million, and of this £1,137,900, roughly a quarter was spent in the Commonwealth, mostly in Africa, and the rest at home on scientific, medical and social projects and on fellowships With regard to the last it may be noted that since 1946, 357 travelling fellowships have been awarded, and from the beginning the Foundation has made a special point of enabling the married overseas fellow to be accompanied by his wife and for its married Fellows has provided a small colony of furnished flats in Prince Albert Road, London. Travel grants during the year have covered the visit to England of Mr. R. C. Robinson, a neurosurgeon from the University of Otago Medical School; a visit to Dr. D. G. Abraham, Ibadan, by Dr. Wallace Brigden to study a puzzling heart condition; a lecture tour in Canada by Sir Christopher Ingold, arranged by the Chemical Institute of Canada; and a study visit on Commonwealth constitutional law by Prof. C. H. Alexandrowicz, of the University of Madras. Three medical fellowships, three fellowships and four scholarships in dentistry were awarded during the year, but the scheme for sociological scholarships and bursaries was discontinued and a new scheme of senior sociological scholarships initiated experimentally for three years. Only one travelling fellowship for Home Civil servants was awarded, but eight travelling fellowships were awarded in medicine, twelve in natural science, and nine in humanities and social science, while twenty-three awards were made under the Royal Society–Nuffield Foundation Commonwealth bursaries scheme.

In this report the Foundation, welcoming the new emphasis placed by the Government on the teaching of technology, records that, after considering how best it could help without trespassing on public responsibilities, the Foundation has decided that its chief interest should be in the technological colleges providing advanced courses. These colleges have a different purpose from the technological departments of universities, deriving from the belief that some students mature better if their theoretical training is more closely interwoven with industrial practice than is usual or desirable for university students. It considers that all such colleges need to establish a fruitful partnership with the industries with which they are most intimately associated, and while refraining from adopting a detailed programme of schemes for sandwich courses, for example, for which it would be willing to provide grant-aid, has indicated its interest in experimental schemes designed to achieve closer unity between the colleges and industry and in schemes which would benefit technological industry generally. As regards support for research at Commonwealth universities and institutions of like standing, the emphasis during the year has been on Africa.

In science, three grants of £50,000 were made during the year: one to the University of Edinburgh for fundamental research under Profs. M. Swann and C. H. Waddington on fibroblasts which may throw some light on the causes of rheumatism; another to the British Museum (Natural History) for the purchase of about half the collection of meteorites formed by Mr. H. H. Niniger, of Arizona; and the third, over five years, to the University of Cambridge for the development by Dr. M. V. Wilkes, of the Mathematical Laboratory, of a much faster digital computer, *Edsac* 3, capable of solving partial differential equations. Among other grants may be noted a further £9,000 over three years in support of the study of protein metabolism and particularly connective tissue under Prof. A. Neuberger at St. Mary's Hospital Medical School; £4,350 over three years for an investigation by Dr. I. Rorison, of the University of Nottingham School of Agriculture, of the effects of aluminium on plant growth; £11,000 over three years for the biochemical and physiological investigation of cell division and expansion in the meristems of the shoot and root at the University of Edinburgh; and a further £5,250 over three years to enable Dr. A. G. M. Weddell to continue his studies at the University of Oxford on the mechanisms of common sensation; and £1,690 a year for three years to King's College, London, for an investigation of the cell cortex and cell movement under Prof. J. F. Danielli.

In technology a research unit for psychological and social research on problems of technical education and human factors in industry has been established at Brunel College of Technology, Acton, with the help of a Foundation grant of £15,000, and £12,000 over five years was also offered to the University of Birmingham to establish a research unit in the Institute of Education under Prof. E. A. Peel to study and advise on the placing, counselling and teaching of part-time technical college students.

Apart from the grants to the University of Edinburgh for work on fibroblasts and the nature of the enzyme systems involved, all other new grants for research in rheumatism have been made to departments or projects already supported by the Foundation. These included £3,000 over three years for an electron microscope study at the Rheumatism Research Centre, University of Manchester, of the fine structure of the fibroblast in different phases of its metabolic activity, and £4,100 to the University of Sheffield for work under Dr. H. F. West in the Sheffield Centre for the Investigation and Treatment of Rheumatic Diseases. Other grants for medical research have included £25,000 over five years for a metabolic research unit at the Institute of Urology, University of London, and £20,000 towards the capital expenditure at Banstead Place and Dorincourt of two units for the rehabilitation of young chronic sick, chiefly for building and equipping a physiotherapy unit at Banstead Place.

Grants in the United Kingdom for social research and experiment in education include one of £7,500 over three years to the School of Architecture, University of Cambridge, for studies of urban reconstruction, particularly of urban housing in relation to daylight, sunlight and open space, including the provision of special apparatus, such as an artificial sky and the necessary measuring instruments for the study of day-lighting. A grant of £4,000 for two years was made to the Christian Frontier Council in aid of a study of the notion of equality in modern society with special reference to its implications for politics, industry and education, and for the pursuit of the ideals of excellence; one of £2,200 to the University College of North Staffordshire to enable a study of Parliament on the lines of a pilot study completed for 1955–58 to be made for the period 1945–55; a grant of £1,250 to the Institute of Race Relations, London, for a study of the integration of alien or minority groups of workers (chiefly West Indians and Poles) in an industrial situation in the London area; one of £3,700 to the School of Social Studies, University of Sheffield, for an inquiry by Mr. R. R. Kelsall into wastage, after training, among women teachers in England and Wales. A grant of £2,000 was made to the University of Manchester to enable Prof. S. Devons to try out his scheme of using honours graduates in physics part-time on research at a university and part-time on school teaching to relieve the shortage of first-class teachers of science in grammar schools, and £8,500 was offered to the Scottish Council for Research in Education to permit a follow-up survey between eleven and eighteen of the mental survey of the whole eleven-year age-group of more than 70,000 children in Scotland made in 1947, while up to £3,500 was offered to initiate "Youth Ventures", a non-profit making company intended to provide an unconventional youth service to fill in the gaps until the 'new towns' are more fully developed commercially.

In the field of research in ageing and care of old people, £6,000 was provided to the University of Cambridge for further studies of the economic position, and a grant of £3,700 to the University of Bristol for studies of the employment of older workers was renewed for a sixth and final year. The University of Birmingham received another £6,500 for Prof. P. L. Krohn's unit studying the ageing ovary, and the University of Leeds £6,000 for a further year's study by Dr. D. A. Hall's team of the changes taking place in connective tissue and the processes concerned in the degradation of such tissue during ageing, while £4,500 over the next three years was provided for work on physiological and pathological changes in the aged under Dr. E. Woodford-Williams at the Sunderland General Hospital.

Among grants for the Commonwealth Overseas during the year are £3,000 over two years for a study of the normal lymphatic system in typical primates, and £3,320 over two years for studies on the helminthic fauna of freshwater fish in Central Africa at the University College of Rhodesia and Nyasaland; up to £50,000 including a capital grant up to £30,000 over five years for an experiment in rural education by the Ministry of Health, Kenya; £5,000 to University College, Ibadan, in support of epidemiological field work in Nigeria; £3,000 as an emergency measure to extend the life of the Medical Research Unit, University of Natal; £20,000 over two years to the East African Agriculture and Forestry Research Organization for grassland reclamation in the Ngorongoro Crater highlands; a further £5,000 to the Gayaza Girls' High School for its study of farming and a balanced diet; a further £5,750 to the University College of East Africa for its swamp research; £13,850 for the study of urbanization in the Sierra Leone Protectorate being undertaken by the University of Edinburgh under Dr. K. L. Little; £12,000 for five years to the radio education unit of the University College of the West Indies; £20,000 over three years on a tapering basis to the Government Central Pedalogical Institute, Allahabad, for teaching English; up to £4,000 to the University of Hong Kong to enable Prof. J. E. Driver to purchase equipment for his Department of Chemistry, and £3,600 over three years to the Institute of Child Health, Calcutta, for studies of the pattern of disease in a sample group of children.

PROGRESS IN FOOD INVESTIGATION

FOR many years the annual report published by the Department of Scientific and Industrial Research under the title "Food Investigation" has reviewed the work of the Food Investigation Board and of three research institutes, namely, the Low Temperature Research Station at Cambridge, the Ditton Laboratory, Maidstone (with its associated unit at Covent Garden), and the Torry Research Station, Aberdeen.

In 1958 the Council of the Department of Scientific and Industrial Research decided on a series of administrative changes: (1) to disband the Food Investigation Board; (2) to retain the Torry Station as an independent establishment of the Department; (3) to transfer the other two institutes to the Agricultural Research Council. This latter change was brought about "because the two Councils believe that it is in the national interest to bring all Government research on food, other than fish, under one organization, the aim being to make the research more effective". From now onwards a report on the Torry Research Station will be published annually by the Department of Scientific and Industrial Research; the report, "Food Investigation 1958"*, is limited to the Cambridge and Ditton Laboratories and will be the last to appear under the auspices of the Department.

The Cambridge and Ditton Laboratories are complementary to one another: at Ditton the emphasis is on problems associated with fruits and vegetables; at Cambridge, although important work is being carried out on plant tissues and products, the major stress has been on animal products—meat (including bacon and poultry), eggs and animal fats. At both centres there have been fundamental investigations in biochemistry, biophysics and microbiology, and the report illustrates how difficult it is (in any event in the field of food technology) to draw a distinction between pure and applied research; the examination of the factors governing the quality of meat, eggs or fruit has stimulated basic work on the chemical composition of these materials and on the nature of the enzymes present; in turn, the newer information obtained has helped in the solution of practical problems of food storage and preservation.

The Cambridge section of the report includes summaries of investigations on three recent developments in food technology, namely, the administration of œstrogenic hormones to young animals (to increase the rate of gain of weight and the efficiency of food conversion), the use of antibiotics in poultry storage and of radiations in meat preservation. Details are given also of recent research on the phenolic constituents of plants; these compounds—ranging from relatively simple molecules to complex polymers—are now known to play a significant part in the control of colour, flavour and texture in a wide variety of foods.

The Ditton Laboratory records the increased commercial use of the hydrocooling process for vegetables such as watercress and lettuce; controlled experiments have shown that vegetables subjected to this process should arrive fresher on the market and retain their quality for a longer period. Another important line of research is concerned with the storage of potatoes in bulk using a new method of suppressing sprout growth—the introduction of nonyl alcohol vapour into the ventilation system of the store. An account is given also of various lines of research in plant physiology and biochemistry, and in refrigeration and other aspects of 'biological engineering'.

The food industries in the United Kingdom owe a debt of gratitude to the Department of Scientific and Industrial Research for sponsorship of research over some decades; the annual reports of the Food Investigation Board and other publications from the individual laboratories have played an indispensable part both in stimulating industrial research and in placing food storage and processing in the United Kingdom on sound scientific foundations.

FRANCIS AYLWARD

THE HOVERCRAFT

A DEVICE for forcing out compressed air between a ship's surface and the water was patented in 1883. It did not work. Many similar fruitless attempts were made in the next sixty years until, in 1953, Mr. C. S. Cockerell began experimenting with air lubrication. His success is now universally recognized and the first hovercraft has begun the hard task of practical development, foreshadowing a new contender in the field of maritime transport.

Cockerell began as had De Laval, by attempting to contain a sheet of air between the surface of a vessel, in this case a planing craft, and the sea. He found that the reduction in drag was offset by the hull modifications needed to supply the air. He then attempted to contain the air lubricating sheet between vertical plates but these plates increased the skin friction drag. The answer was to replace the solid containing plates by curtains of air and so the hovercraft was evolved.

The experimental version now flying, the 'SR-NI', is an oval dish on top of which are mounted the propulsion and control systems, and the air compressor. The compressor is a 7-ft. diameter ducted fan powered by a 435-h.p. internal combustion aero engine. Two-thirds of the compressed air is fed to two concentric annular slots near the periphery of the under surface of the oval disk. The slots are shaped so that two continuous jet sheets are directed downwards and slightly inwards. When the engine is started the jets first build up the air cushion under the disk and then maintain the pressure difference between the cushion and the atmosphere. The pressure difference deflects the air curtains and they spill outwards at the ground or water surface (the pressure difference times the height above the ground must equal the radial rate of change of momentum). Two curtains are used for stability reasons. A third of the compressed air is bled off into two parallel propulsion ducts of rectangular cross-section which lie along and above the flat sides of the oval disk. Vanes at each end of each duct provide the necessary longitudinal and lateral control.

Because the weight that can be supported is dependent on the disk area while the power required is proportional to the peripheral length, the economy of a hovercraft should improve with size. A reasonably flat operational surface is required and early applications may well be over surfaces which existing vehicles find difficult, for example, marsh, snow, sand, ice and shallow rivers. Serious consideration has been given to a 400-ton car ferry capable of carrying eight hundred passengers and eighty cars across the channel at a speed of 90 knots. A careful detailed study of hovercraft economics suggests a cost of between 8 and 18 pence per (payload) ton (nautical) mile in the speed-range 70–170 knots. Both cost and speed lie somewhere between the current values for ships and commercial aircraft. If the hovercraft can prove its worth with modest payloads over short distances, then serious thought could be given to developing a trans-ocean hovercraft capable of crossing the Atlantic in 24 hr. This new competitor could not appear within the next ten years, however, and one wonders what the level of ship and particularly aircraft fares will be by then. Nevertheless, the hovercraft has an extremely interesting future and one can only congratulate the inventor and the development engineers on their achievement and remark that this is one enterprise where the Old World leads the New.

These remarks are based on a paper "The Hovercraft—a New Concept in Maritime Transport", by P. R. Crewe and W. J. Eggington, read before the Royal Institution of Naval Architects on November 19, 1959. J. L. STOLLERY

NEW DELHI SYMPOSIUM ON ALGAE

POSSIBLY because algae are usually inconspicuous in the temperate regions in which most microbiologists receive their training, the dominant role which these organisms may have in soil and water in other climates is apt to be overlooked. In India, although much excellent work has been done on algae, this has largely followed morphological and systematic lines, and relatively little attention has been paid to their activities and possible economic importance. The symposium on "Algology", held in the Indian Agricultural Research Institute, New Delhi, during December 7–11, under the auspices of Unesco and the Indian Council of Agricultural Research, had the object of stimulating investigations on the more practical aspects of the subject. It was opened by Mr. S. K. Patil, Minister for Food and Agriculture, and was attended by experts from Japan, England, the Federal Republic of Germany, and Israel, as well as by delegates from all parts of India.

An introductory address by Dr. M. S. Randhawa, chairman of the organizing committee, outlined the development of algal studies and lines of research which may be of practical importance. The principal uses to which these organisms may be put are mentioned below, but it may be noted that in the tropics algal growth often needs controlling rather than encouraging—a matter which was not considered in any of the papers which followed. The growth of blue-green algae, which generally occurs on buildings during wet weather, not only renders them unsightly but also corrodes the stone-work and presents a problem of major economic importance. Algal growth may also interfere in the manufacture of salt, it may block canals and irrigation channels, and pollute fresh water.

The papers presented covered nearly every aspect of modern knowledge of the algae. Classical morphology was represented by papers on the comparative morphology of the Charophytes, by V. S. Sundaralingam, and on reproduction in red algae, by M. S. Balakrishnan, and by a lecture by M. O. P. Iyengar, describing some of the many interesting species which have been discovered in India. Recent advances in the study of the submicroscopic morphology of algae were reviewed by T. V. Desikachary, who also discussed the structure of diatom frustules in the light of his own electron microscope investigations. Papers on algal cytology, which is especially important for the understanding of life-cycles and for taxonomy, were given by C. S. P. Rao, Y. S. R. K. Sarma and Y. B. K. Chowdary.

One of the most important of recent advances in algal physiology has been the introduction by H. Tamiya and his associates of the technique of synchronous culture as a means of studying the metabolic changes occurring during the life-cycle. A paper by H. Tamiya summarized the main results obtained and dealt particularly with the role of sulphur in the processes of cell maturation and division. Studies on the mineral nutrition of a *Selenastrum* were described by K. V. Natarajan. In a lecture on the extracellular products of algae, G. E. Fogg presented evidence showing that the liberation of these is widespread and that enzymes are included among the very varied kinds of substances involved. These extracellular substances may be of ecological importance in various ways, as, for example, by forming chemical complexes with inorganic ions. The kinetics of the production of extracellular nitrogenous substances by a nitrogen-fixing *Nostoc* isolated from the root nodules of *Trifolium alexandrinum* was discussed by G. S. Venkataraman. In another paper on nitrogen fixation, G. E. Fogg emphasized the close intermeshing of this process with photosynthesis which occurs in blue-green algae. He also reported nitrogen fixation by *Chlorogloea fritschii*, evidently the first unicellular member of the group in which this property has been demonstrated unequivocally. A paper by A. Watanabe dealt with the importance of blue-green algae in rice-fields. Nitrogen-fixing blue-green algae are found almost ubiquitously throughout tropical, sub-tropical and temperate regions and evidently contribute materially to the fertility of many soils. It has been found possible to grow *Tolypothrix tenuis*, a particularly vigorous nitrogen-fixing species, on the large scale and to preserve it as a culture on porous gravel. Inoculation of paddy fields with this has resulted in appreciable and long-continued improvements in yields of rice.

H. Tamiya, H. von Witsch and A. M. Mayer each considered various aspects of the mass culture of microscopic algae such as *Chlorella* for use as animal or human food. The average yields of *Chlorella* grown on the large scale correspond to the production of 14,000 lb. of protein per acre per year, whereas the corresponding figures are 600 lb. for grass, 420 lb. for peanuts, 90 lb. for milk and 54 lb. for meat. The results of feeding tests demonstrate that the alga is of high nutritive value. Convincing evidence of the feasibility of large-scale culture was given in a film of the work of the Japan Micro-algae Research Institute. This has culture ponds of about an acre in total area producing 12 tons dry weight of *Chlorella* a year, which is largely used as a source of growth factors for the commercial culture of *Lactobacillus*. As a means of producing material which can be used directly in human or animal nutrition the process is not yet an economic one; the estimated cost of decolorized algal powder is 1·12 dollars per lb.—considerably more than that of cheap protein sources such as soy beans (0·06 dollar per lb.) or fish meal (0·13 dollar per lb.) but a little less than that of skim milk powder (1·20 dollars per lb.). In arid regions this high cost may be offset by the high degree of water conservation which is possible with algal cultures as compared with conventional crops, but for more general use cheaper methods are essential. To suit Indian conditions, it would be desirable to simplify the process so that it might be operated by peasants, and to this end M. O. P. Iyengar suggested that an examination should be made of algae known to grow prolifically in Indian fresh waters and which might be harvested easily.

The cost of algal culture can be minimized by combining it with the photosynthetic treatment of sewage and organic wastes by the oxidation pond method. A paper submitted from the Sanitary Engineering Laboratory of the University of California gave a résumé of this process and reported that algae harvested from oxidation ponds by alum flocculation proved satisfactory as a protein source in the diet of lambs. Field studies carried out at the Engineering College, Guindy (Madras), on the use of algae in sewage disposal, described by A. Raman, indicate that the method can be used under Indian conditions.

In a general lecture on the use of algae as food, H. Tamiya, besides describing the possibilities of *Chlorella*, gave an account of the use of seaweeds for this purpose in Japan. Among these, the most popular is *Porphyra tenera*, which is cultivated in shallow seas to the extent of 4,000–5,000 tons dry weight per annum and which can command prices of up to 8.00 dollars per lb. The amounts of marine algae available around India are relatively small, but a paper by F. Thivy showed that there are, nevertheless, possibilities for their use as food and described cottage industry methods for the preparation of seaweed meal and agar. The ecology and distribution of Indian marine algae were considered in papers by J. N. Misra and K. S. Srinivasan.

Phytoplankton ecology was discussed in four papers. V. P. Singh described detailed observations made over a year on two lakes in Uttar Pradesh, the plankton of which is dominated by *Microcystis*. M. T. Philipose and S. V. Ganapathi gave more general descriptions of Indian freshwater phytoplankton in relation to fisheries and water supply. The marine phytoplankton of the west coast of India was considered in special relation to fisheries by R. Subrahmanyan. The indications are that the phytoplankton production could support a considerably higher rate of fishing than it does at present.

At the final session a number of recommendations were approved for the extension of algal research in India on a broad front with the ultimate object of making more practical use of these organisms.

G. E. Fogg

EROSION OF METEORITES IN SPACE AND THE DENSITY OF INTERPLANETARY GAS

By Dr. L. REIFFEL

Physics Division, Armour Research Foundation, Illinois Institute of Technology, Chicago

THE etching rate, due to interaction with interplanetary gas, for the Sikhote-Alin meteorite fall has been estimated[1] as $\lesssim 2 \times 10^{-7}$ cm./yr. from an exposure life-time of 5×10^{8} years, as determined by argon-38/argon-39 age measurements. From this result, Whipple[2] has suggested that the maximum possible proton density of interplanetary space in the vicinity of the Earth is as shown in column 3 of Table 1. Whipple assumes that meteoritic etching is due solely to sputtering from solar protons and uses normal incidence sputtering yields for protons on iron as follows: 0·5 atom/proton for 10,000 eV. or more, 0·2 at 500 eV. and $\sim$0·02 at 100 eV. In the actual calculation, these yields are doubled to account, approximately, for the greater yields which are manifest at smaller angles of incidence.

The purpose of this article is to point out that solar protons are probably not the major factor in determining etching rates from sputtering by gas clouds ejected from the Sun. Calculated upper limits on interplanetary gas densities and erosion rates near the Earth may be changed appreciably as a consequence of including sputtering by elements heavier than hydrogen, and are uncertain for other reasons as discussed below.

In spite of the lower abundance of helium relative to hydrogen, the greater momentum transfer and sputtering efficiency for this ion dominate the meteoritic sputtering process under the assumptions: (1) the ejected solar gas has a chemical composition approximately duplicating that of the solar corona; (2) significant fractionation of helium does not occur in the solar acceleration and escape processes. Since solar streams appear to be "segments of the corona, blown out bodily"[3], these assumptions do not appear unreasonable. In this connexion, it should be noted that Shklovskii's discussion[4] of sources for helium in the terrestrial atmosphere gives strong support to the view that the stream composition is similar to that of the Sun itself. If helium ions travel along in the ejected clouds with the same velocities (column 2 of Table 1) as the stream protons, they will, of course, have four times as much energy, and their relative flux will be the same as their relative abundance. The atomic abundances of hydrogen and helium in the solar atmosphere are difficult to determine. Neven and DeJager[5] suggest an hydrogen/helium ratio (δ) of 20/1 while Unsold[5] finds 5/1. Recently, Aller[6] has given 7/1 as the best value currently available.

Sputtering yields do not appear sensitive to energy for either hydrogen or helium ions in the range 1–10 keV. according to recent measurements by Grønlund and Moore[7]. These data, obtained with analysed beams known to contain only ions, refer to silver targets, but iron is expected to behave in a very similar manner. The ratio of helium ion sputtering efficiency to hydrogen sputtering efficiency (β) is roughly fourteen over the entire range studied. We shall compare hydrogen and helium yields at the same energy, thereby implicitly allowing for somewhat reduced acceleration efficiency for the heavier ions, and shall assume that the relative sputtering efficiency will not change radically when yields are integrated over all angles of incidence. Using the appropriate abundance and allowing for differences in sputtering efficiency, it is seen that the helium erosion is comparable to, and probably exceeds, that due to hydrogen, implying that Whipple's upper limit to the solar proton density can be markedly reduced if the effect of helium is included. Specifically, if N'_p is the proton density calculated by Whipple, one may write for the corrected proton density N_p:

$$N_p = N'_p\left(1 + \frac{\beta}{\delta}\right)^{-1}$$

Here I have retained Whipple's assumptions in allowing for angular dependence of yield (a factor of 2), absolute sputtering yield for protons (as listed earlier) and scaling from fluxes at the meteorite orbit to those near the Earth (a factor of 3/2). Results calculated from this expression, using $\delta = 7$ and $\beta = 14$, are shown in column 4 of Table 1. Including the high Z elements other than helium would reduce N_p still further, but unless their sputtering efficiency is surprisingly high, the change would not be large.

The figures of column 4 are low enough (especially at the higher velocities which, on the basis of other evidence, seem to be most probable) that one becomes concerned about maintaining explanations of a variety of other astrophysical and geophysical phenomena, which, in the past, have led to 'conventional' solar gas densities (at 1 A.U.) between 10^2 and 10^3 protons/cm.^{3} under quiet conditions with estimated velocities varying upward from 500 km./sec. Furthermore, Russian observations[8], while unfortunately not providing velocity information, have recently yielded measured densities which also lie between 10^2 and 10^3 protons/cm.^{3}. Recent laboratory sputtering results using analysed beams are of especial interest in this situation since they are markedly lower than the figures employed by Whipple which were obtained by Wehner using gas-discharge techniques. If one assumes that absolute yields of the order of those observed by Grønlund and Moore for protons on silver (0·035 at 5,000 eV.) are also appropriate for iron, the allowable proton densities rise markedly as shown in column 5 and come into conformity with estimates from phenomena other than meteoritic erosion. It may be that resolution of the somewhat conflicting requirements on fast (for example, >500 km./sec.) solar stream densities implied by meteoritic life-times and other types of observations lies, at least in part, in the reduced sputtering by beams containing only atomic ions. Completely ionized beams would be the rule in space, but perhaps have not been attained in most laboratory sputtering experiments. On the other hand, if the average solar proton velocities prove to be 300 km./sec. or less, one need not appeal to explanations of the sort suggested here.

Table 1. PROTON DENSITIES NEAR EARTH AS INFERRED FROM METEORITIC EROSION RATES

(1) Proton energy eV	(2) Proton velocity km./sec.	(3) Number* per cm.^{3}	(4) Number† per cm.^{3}	(5) Number‡ per cm.^{3}
500	310	290	95	1,000–1,500§
1,000	440	140	45	650
5,000	980	40	13	186

* After Whipple.
† Corrected for sputtering by helium.
‡ Corrected for sputtering by helium and using analysed beam sputtering yields.
§ Rough estimate using $\beta = 14$, which may not hold for this energy.

Finally, it should be noted that any of the results given in Table 1 must be viewed with caution for a number of reasons beyond those already discussed:

(1) The meteoritic etching rate employed at the outset may refer to heliocentric orbits at relatively high angles to the ecliptic and therefore may be anomalously low. Many meteors have been observed in 60 degree orbits. It appears that the solar corona, and probably solar streams, are markedly more dense in the ecliptic[9]. Determination, from fall data, of the orbits of meteorites is difficult and generally unreliable[10], hence study of a statistically significant number of meteorites would be highly desirable before reaching final conclusions.

(2) Energy transfer from the ions to the electrons in the region of solar stream instability may occur[11] and might be accompanied by a spreading of the solar streams away from the ecliptic, resulting in reduced particle densities. If the admittedly speculative transfer process is effective, some shift in the particle energy spectrum would be produced in the region beyond 1–2 A.U. Thus, in the asteroid belt, where the meteorite may have spent the greater part of its exposure life-time, it would be bombarded by an electron spectrum of higher energy and a proton spectrum of lower energy than that characteristic of the inner solar system. Decreased sputtering would result, so the relative gas densities and erosion-rates near the Earth would increase.

(3) If the meteorite originated in the asteroid belt and was deflected into an Earth-capture orbit in a

collision, it may have spent some of its life well beyond 2 A.U., since most asteroids have mean distances from the Sun lying between 2·0 and 3·5 A.U., but are found over a much wider range. Other than by statistical arguments, it does not seem possible to state definitely that the meteorite spent most of its life in an unperturbed Earth-capture orbit with orbital elements near those of the Earth itself. Thus, a square-law dependence of solar stream densities could introduce appreciable uncertainty in scaling from the meteorite orbit to a circular orbit of 1 A.U. radius.

Direct measurement of both erosion rates on known surfaces, as well as particle densities and velocities in space near the Earth, would obviously be of great value, as would collection and analysis of additional data on meteoritic etching rates. Experiments are planned in various laboratories to make direct observations on interplanetary proton densities. In the present context, it would seem desirable to attempt simultaneous measurements on helium.

DIETARY PHYTATE AS A POSSIBLE CAUSE OF MAGNESIUM DEFICIENCY

By DR. A. HEULWEN ROBERTS and PROF. JOHN YUDKIN

Department of Nutrition, Queen Elizabeth College, University of London, W.8

WE have recently made a study in the rat of the effects of dietary phytate upon intestinal phytase and bone calcification. A short account of some of the results has been published[1].

During the course of these observations, we found that rats given sodium phytate in purified diets became severely ill. We believe that this was due to a conditioned deficiency of magnesium, brought about by the soluble phytate combining with the dietary magnesium, which consequently becomes insoluble and unavailable.

The basal purified diet was made up of sucrose 60, low-vitamin casein 20, arachis oil 15, salt mixture 5. Additions of sodium phytate (Ciba) were made at the expense of sucrose. Vitamin supplements were given separately. Most of the experiments were carried out with a strain of albino rats; in a few experiments we used hooded rats of the Lister strain, and obtained similar results, though this strain appeared somewhat less sensitive to phytate. This recalls the observation on chronic magnesium deficiency in two similar strains, described by Watchorn and McCance[2].

We observed the signs of phytate intoxication in albino rats with levels ranging from 1 to 10 per cent sodium phytate in the diet. The animals were put on the experimental diet at 24 days, when they weighed about 45 gm. At a level of 10 per cent phytate, the rats developed severe diarrhœa within 24 hr. and rapidly lost weight. Within a week, seven out of the eight rats in this group had died, having lost about 10 gm. body-weight. The last rat survived for four weeks, but at the end of that time weighed 64 gm., about one half the weight of the control animals receiving no phytate.

With 7½ per cent sodium phytate, severe diarrhœa again developed in the first day, but subsided during the second week. The rats lost weight during the first week, then began to put it on again. They were nevertheless much thinner than normal, with a coarse staring coat and bald patches. The nose was swollen and covered with a dark red bloody exudate. The abdominal wall was hard, and there was often priapism. The animals were very irritable and difficult to handle. They died after about 18 days on the experiment, weighing about 80 gm., with evidence of having passed blood rectally.

With 5 per cent sodium phytate, diarrhœa also occurred, but less severely and rather later. The rats gained weight slowly after the first week. They also developed swollen noses with exudate. One out of the four animals had a convulsive fit in the third week, and showed paralysis from the waist downwards. It lay on its side, breathed very rapidly and died within 24 hr. The others died after about 25 days, weighing about 105 gm. Hooded rats showed an exactly similar response to 5 per cent phytate.

With 2½ per cent sodium phytate, there was only slight diarrhœa in the first week. Bloody exudates again appeared on the noses of the rats. Two out of four rats had convulsive fits and developed paralysis a few days before death. All of them died after about 50 days, weighing about 150 gm.

With 1 per cent sodium phytate, there was no diarrhœa. The bloody nasal exudate appeared in two out of four rats. Growth was better, though still less than that of the control animals receiving no phytate. One rat was found dead after five weeks, and one after eight weeks; there was no sign of convulsions or of paralysis. The other two rats survived at least nine weeks. On this level of 1 per cent sodium phytate, 16 hooded rats showed no signs other than diminished growth.

At first, we examined the possibility that the signs were due to deficiency either of calcium or of inositol. Calcium deficiency could arise by the phytate making the dietary calcium unavailable. We did not think that calcium deficiency was very likely; while it might perhaps account for the convulsions and paralysis, the other signs have not been described in calcium deficiency. Moreover, the toxicity produced by phytate did not occur with dietary citrate, which like phytate would have rendered calcium unavailable. Nevertheless, we tried to cure or to prevent phytate toxicity by the addition of calcium to diets containing phytate, or by the parenteral injection of calcium gluco-galacto-gluconate ('calcium Sandoz'). We found no difference in the signs produced by phytate when the rats were given calcium.

Inositol deficiency could arise by competitive inhibition, since phytate is inositol hexaphosphate. Moreover, the signs we observed were similar to those which had been reported for inositol deficiency in rats. We therefore gave 50 mgm. inositol daily, in addition to the 1·1 mgm. contained in the routine vitamin supplements, to half of a number of rats receiving varying levels of phytate from the age of 24 days. This made no difference in growth or in the development of signs of phytate intoxication.

We now examined the possibility that phytate intoxication was due to magnesium deficiency. We recalled that Kruse, Orent and McCollum[2] and Watchorn and McCance[3] had reported signs of magnesium deficiency in rats, which resembled those in our rats showing phytate intoxication. We therefore gave levels of phytate up to 7½ per cent to groups of eight animals; four on each level had in addition 10 gm. magnesium sulphate to 100 gm. diet. The additions were made after the animals had been on the control or phytate diets for three weeks, or (with 7½ per cent phytate) two weeks. The general effect of the magnesium supplements was to improve the appearance of the animals; for example, the nasal exudates were much reduced, and there were no bald patches. There was no effect on the growth of the animals receiving 1 per cent phytate, but there was improved growth and longer survival in those receiving 2½, 5 or 7½ per cent phytate. In the 5 per cent group, for example, the rats receiving magnesium gained on average 20 gm. in weight in the week following the addition, whereas those not receiving the magnesium gained 8 gm.; the rats receiving magnesium survived at least 56 days, whereas those not receiving it died after an average of 41 days.

In this experiment, there were two animals which showed exceptional responses. One was receiving a diet with 1 per cent sodium phytate; it was also given magnesium supplements, but in spite of this it died in convulsions. The second animal was receiving a diet with 7½ per cent phytate; it was not given magnesium supplements, yet nevertheless it showed no signs of phytate intoxication throughout the experiments. These great variations between individuals in the development of signs of hypomagnesæmia are well known in cattle (Allcroft, R., personal communication). Apart from these individuals, however, all the rats receiving 2½ per cent or more of phytate without magnesium were either found dead, or developed fits and died within 24 hr.; all the rats receiving the same diets with magnesium gained weight and survived for the duration of the experiment and showed little if any signs of intoxication.

A second experiment was carried out with five groups, each of eight rats. One group received no phytate, two groups received 5 per cent phytate and two groups 7½ per cent phytate. One group on each level of phytate was given in addition magnesium sulphate at the rate of 10 gm. per 100 gm. diet. The rats on the phytate-free diet, or on the phytate diets with magnesium sulphate, all grew and survived until the experiment was terminated after nine weeks. Those receiving 5 or 7½ per cent phytate with no magnesium grew badly, and died on average at 42 days or 20 days (see also Fig. 1). Although the addition of magnesium greatly improved the condition of the animals receiving phytate, their rate of growth was lower than that of the controls receiving no phytate.

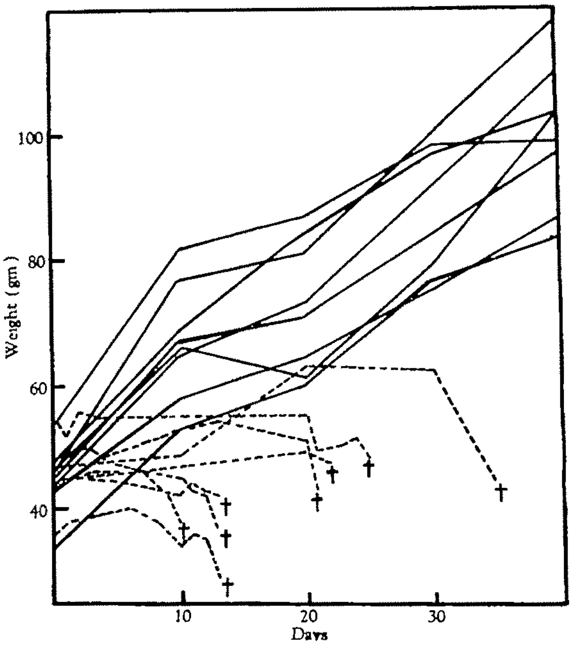

Fig. 1. Effect of addition of magnesium to a diet containing sodium phytate

All rats were given a purified diet with 7·5 per cent sodium phytate from age 24 days Curves represent weight changes in individual rats. ——, diet with 10 per cent magnesium sulphate; – – –, diet without magnesium sulphate

Since our work was primarily designed to study quite a different problem, we have not yet pursued the many questions which are raised by these results. In particular, we have not examined levels of magnesium in the blood. Nor have we at present facilities for studying the condition in ruminants. We believe, however, that we have reasonable circumstantial evidence that diets which include phytate may cause magnesium deficiency.

We may summarize this evidence as follows: (1) soluble phytate can form insoluble mixed salts of calcium and magnesium; (2) the signs of intoxication shown by rats given diets rich in phytate resemble those described in rats given diets deficient in magnesium; (3) rats show a varying individual susceptibility to phytate intoxication, recalling the known variability of signs of magnesium deficiency in cattle; (4) the signs of phytate intoxication are to a great extent prevented or cured by the administration of magnesium; (5) the doses of magnesium needed to prevent or cure the signs of phytate intoxication in rats are surprisingly large, again recalling the situation in hypomagnesæmia in ruminants.

We suggest, therefore, that a dietary constituent such as phytate, which can render magnesium unavailable, may be a cause of hypomagnesæmia in adult ruminants. It is likely, for example, that this is the explanation of the results of McAleese and Forbes[4], who showed that a diet high in roughage can cause hypomagnesæmia in lambs. The roughage included corn cobs, and corn cobs were also used for bedding. Although we do not know how much phytate was consumed, and how much of it was soluble phytate, it is likely that the small amount of dietary magnesium was still further reduced by combination with soluble phytate.

Our hypothesis could also explain why the level of serum calcium is often decreased in hypomagnesæmia in adult cattle[5]. Substances such as soluble phytate form insoluble salts with calcium as well as magnesium, so that excess of dietary phytate would lead to decreased absorption of both.

The confirmation of our hypothesis requires much further work. In particular, we need to know the effect of dietary phytate on the magnesium and calcium levels of blood, and whether the pastures which cause hypomagnesæmia in ruminants contain high amounts of phytate or some other constituent which binds the magnesium.

FLUORESCENCE STUDIES OF CHLOROPLAST DEVELOPMENT IN *EUGLENA*

By Dr. H. T. EPSTEIN* and E. BOY de la TOUR
Biophysical Laboratory, University of Geneva
AND
Dr. JEROME A. SCHIFF
Biology Department, Brandeis University, Waltham, Mass.

EUGLENA should be an excellent organism for the study of control and biosynthesis of a new organelle in response to a highly controllable and defined external stimulus because the chlorophyll-free and presumably chloroplast-less dark-grown organism is believed to develop both rapidly after being placed in the light. An early electron microscope study[1] of the transition seemed to show no detectable chloroplasts in dark-grown cells. As pointed out by Nishimura and Huzisige[2] the results of that work are questionable because Wolken and Palade reported the presence of a very considerable amount of chlorophyll in their dark-grown cells whereas in cells grown for many weeks in the dark there is no trace of chlorophyll[2,3]. Indeed, with so much chlorophyll present, it would be expected that some chloroplast remnants would have been found.

The fact that chlorophyll has a strong red fluorescence suggested to us that it might be possible to follow the developing plastids by direct observation with the light microscope under conditions of dark-field illumination. A similar technique has been used by Strugger[4] and by Heitz and Maly[5] for the chloroplasts of higher plants.

Light from a mercury arc was filtered to pass only 435 mμ; a yellow filter in the eyepiece eliminated interference from the light source. A preliminary look at light-grown cells revealed a spirally arranged set of red-fluorescing structures with the typical disk shape of chloroplasts. A similar look at dark-grown organisms revealed a spirally arranged set of light pink structures scarcely larger than points.

The following technique was developed to immobilize the cells for photography. A 5 per cent solution of polyvinyl alcohol in distilled water is prepared by boiling lightly and letting it stand overnight at room temperature to ensure that the alcohol is fully dissolved. A few drops are placed on a clean glass microscope slide and spread over the entire slide; these dry face up for at least 2 hr. at 37° C. A cover should be placed over the slides to prevent dust from falling on them. We find such slides still usable after as many as 3 days in the incubator. Gelatin and agar were tried and found to have too great fluorescences of their own.

The dried slide is placed in observation position in the fluorescence microscope. A small droplet of the solution to be studied is placed on a clean cover-slip which is inverted on to the slide. The droplet spreads and is rapidly absorbed by the alcohol layer, immobilizing the cells. Depending on the stage of chloroplast development, there are 2–10 min. for making pictures before observable deterioration is found. Both 'Ektachrome' and 'Superanschchrome' daylight films have been used, though the former has some advantages for this system because of its greater response in the red.

Euglena gracilis var. *bacillaris* was cultured in Hutner's *p*H 3·5 medium as previously described[6]. At zero time, several ml. of dark-grown logarithmic-phase cells were placed in a test-tube in the light of a daylight fluorescent lamp at room temperature. Samples were studied at various times after the cells were placed in the light. The zero-time samples were taken directly from the culture growing in the dark.

At zero time, the cells usually have one or two pinkish bodies in a line of smaller, paler dots of fluorescence usually running spirally along the organism. The organism itself has a bluish fluorescence; the flagellum is light green. By 15 min., the small dots are visibly enlarged and have become orangish. By 1 hr. the dots are orange-red objects about one-fifth the length of a mature chloroplast. There is some indication that, after this time, some of the increase in size of the plastid may be due to coalescence of several smaller bodies.

By 4 hr., some of the plastids are as much as one-third normal length, and are now quite red. There is an appreciable inhomogeneity of development not only from organism to organism, but also among plastids of the same organism. At about this time, the blue fluorescence has begun to disappear and is essentially gone within another hour or so. Thereafter the plastids develop regularly, on the average, with occasional normal-sized chloroplasts being detectable after about 20 hr. in the light.

There appear to be roughly two types of mature structure. In the majority type there are quite normal-looking plastids with occasional hints of a line of red fluorescence running between some of the plastids. In the minority type the connecting lines are broadened so much as to present a ribbon-like structure with the chloroplasts being detectable only by their being more deeply coloured.

From these observations it may be concluded that there are what must be termed proplastids of an appreciable size (perhaps 1μ) even in the dark-grown organism. It also seems clear that the development involves an actual increase in plastid size as well as in complexity. Thus, it would not be true that the chlorophyll simply vanishes when a green cell is placed in the dark, leaving a structure which can later be refilled whenever chlorophyll synthesis is re-initiated. Preliminary observations with the electron microscope support this conclusion.

The frequent links between chloroplasts remain to be interpreted. Two interpretations may be proposed here. First, the entire chloroplast structure in *Euglena* is to be thought of as a single chloroplast with the normally designated chloroplasts being, in reality, more analogous to the grana of higher plants. Secondly, one might consider that the links are the remnants of connexions between dividing plastids.

Preliminary observations of the reverse processes occurring when light-grown cells are placed in the dark have revealed that the steps are the reverse of the synthetic steps, with, however, a much different time-scale. For example, the blue fluorescence reappears only after more than a day in the dark. The plastids in these organisms remain for many days, being reduced to about one-fifth normal size only after about 2 weeks.

A preliminary survey of our collection of mutants has shown appreciable differences even among different albino mutants. For example, one albino has an overall greenish colour; a second has pale yellow-green plastid-like bodies; and a third has no appreciable fluorescence. A yellow-brown mutant looks normal when grown in the dark, but when grown in the light contains structures similar to those found in normal cells after 10–15 hr. of light.

We have been able to use fluorescence as a criterion of purity of plastids being extracted from organisms at various times after being placed in the light. Also, it now appears likely that the fluorescence may be used as a criterion of functional integrity in such extracts.

Finally, there is one observation that can be made only with the freely moving organisms. The entire chloroplast structure does not move with respect to the cell surface, being apparently fixed in some manner to the cell wall or membrane.

INCORPORATION OF ORTHOPHOSPHATE LABELLED WITH PHOSPHORUS-32 INTO CEREBRAL PHOSPHOLIPIDS *IN VIVO*

By DR. G. B. ANSELL and S. SPANNER

Department of Experimental Psychiatry, Medical School, Birmingham

ALTHOUGH it was originally considered that the rate of incorporation of radioactive phosphate into brain phospholipids *in vivo* was relatively slow, the work of Dawson and Richter[1] showed that the rate of incorporation of label from the trichloroacetic acid-extractable phosphorus compounds of cerebral tissues into phospholipid phosphorus was relatively high. Ansell and Dohmen[2] showed that the incorporation varied for different phospholipids over short time intervals (0–7 hr.), though the difficulties of interpretation are manifold[3]. Marinetti and co-workers have recently published time curves for the incorporation of phosphorus-32 into some of the phospholipids of tissues other than brain for periods of up to 100 hr. following the subcutaneous injection of labelled orthophosphate into adult rats[4]. We wish to record results showing the course of the incorporation of orthophosphate labelled with phosphorus-32 into brain phospholipids and two probable precursors, phosphorylcholine and phosphorylethanolamine, over a period of seven days; some information on the rate of incorporation of phosphorus-32 into the monoesters of brain *in vivo* has been recorded previously[5,6]. The present communication is prompted by a report by Miani and Bucciante who have carried out a comparable study[7].

Three litters of three-week-old rats were injected intraperitoneally with 4μc. labelled orthophosphate/gm. body-weight (supplied in sterile isotonic solution with carrier phosphate by the Radiochemical Centre, Amersham, Bucks) and killed at intervals. Phosphorylethanolamine and phosphorylcholine were separated from the trichloroacetic acid-soluble fraction as previously described[6]. Phospholipids were extracted from the washed tissue and the specific radioactivities of individual phospholipids determined by the method of Dawson[8] as described previously[9]. The results are recorded in Figs. 1 and 2 in which the specific radioactivities of the various fractions (all corrected to the same radioactive standard) are plotted against time.

The specific radioactivity of the acid-soluble fraction of brain tissue rapidly rose and then stayed relatively constant as has been noted by Dziewiatkowski and Bodian[10]; they found that its rate of decline was much slower than that of the blood. The present results (Fig. 1) indicate that phosphorylethanolamine and phosphorylcholine acquire the same radioactivity as the acid-soluble fraction as a whole within 24 hr. Previous observations[6] have shown that after an exchange period of 3 hr. the specific radioactivity of the phosphorylethanolamine in the brain tissue of young animals is only 70 per cent of that of the total acid-soluble fraction, while that of phosphorylcholine is higher, acquiring radioactive phosphate at a rate greater than the majority of other components, but coming into equilibrium with them after 24 hr. As a result of the second observation it was suggested that the choline phosphokinase of nervous tissue must be particularly active *in vivo*. After long exchange periods, however, nothing can be deduced about the relative rates of incorporation of phosphorus-32 into these components of the brain acid-soluble fraction (Fig. 1) and it is likely that all its phosphorus-containing components are in isotopic equilibrium (cf. ref. 11). Miani and Bucciante[7] have presented results indicating that, for animals 6 days old, the incorporation of phosphorus-32 into brain phosphorylethanolamine and phosphorylcholine is maximal 40 hr. after injection, but they do not record the values for the specific radioactivity of the total acid-soluble phosphorus.

It can be seen that several of the phospholipids steadily acquired radioactivity over a time period of seven days (Fig. 2) as was originally observed for phospholipid phosphorus as a whole for both young and adult rats by Changus, Chaikoff and Ruben[12] and afterwards for young rats by Davison and Dobbing[13]. Phosphatidyl serine acquired it at the slowest rate and phosphatidyl choline at a faster rate than that of the ethanolamine-containing phospholipids (cf. ref. 2). Loss of radioactivity from rat brain phospholipids as a whole is apparently very slow[13].

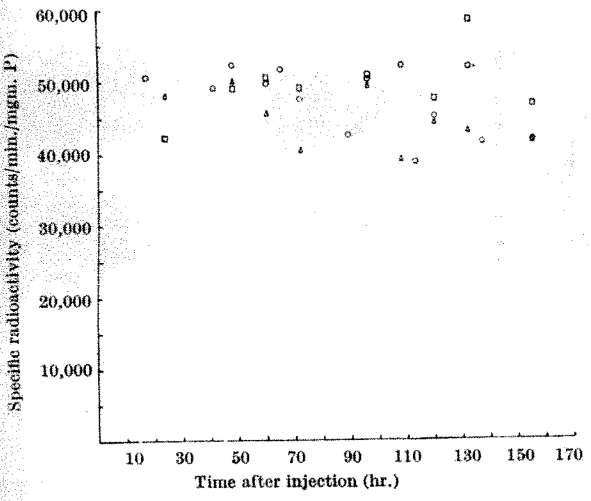

Fig. 1. The specific radioactivity-time scatter diagrams for rat brain acid-soluble phosphorus (○), phosphorylcholine(△) and phosphorylethanolamine (□) after injection of phosphorus-32 labelled orthophosphate when the animals were three weeks old

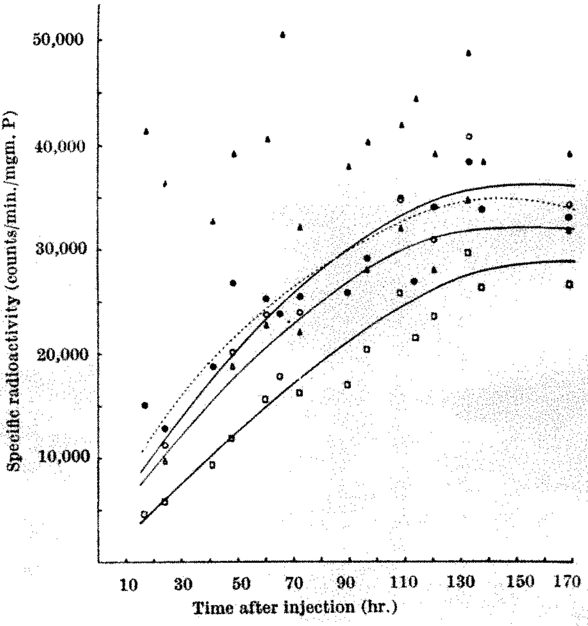

Fig. 2. The specific radioactivity-time curves for rat brain 'diphosphoinositide' (▲), phosphatidic acid (broken line ●), phosphatidyl choline (continuous line ○), phosphatidyl ethanolamine (continuous line △) and phosphatidyl serine (continuous line □)

It was shown previously[3] that 'diphosphoinositide' (more probably a monophosphoinositide[14]) acquired labelled phosphate faster than any other phospholipid and after a short time interval of 3 hr. the specific radioactivity of its phosphorus was about half that of the acid-soluble phosphorus. Phosphorus exchange was apparently proceeding, in fact, at a rate not very different from that of the phosphorylethanolamine in the acid-soluble fraction. The values in Fig. 2 show that after its initial steep rise the specific radioactivity of the inositol phospholipid remained relatively constant; the scatter of the values is due to the fact that the amount of phosphorus estimated in this instance is very small compared with the radioactivity present. Miani and Bucciante[7] have published curves for the long-term incorporation of phosphorus-32 into brain phospholipids of very young rats (4 days old) and of rats of 100 gm. body-weight. Their values for the young animals indicate a sharp peak for the incorporation of phosphorus-32 into 'diphosphoinositide' about 20 hr. after administration of the isotope. The specific radioactivity then rapidly falls away; in the older animals the peak occurs about 60 hr. after administration and is flattened; the specific radioactivity then falls away more slowly. It is difficult to correlate these results with our own observations; for the older animals of Miani and Bucciante, incorporation of label into phosphatidyl choline, phosphatidyl ethanolamine and phosphatidyl serine is the reverse of that found by us for animals three weeks old. For the very young animals in the experiments of the Italian workers, the incorporation in the first 15 hr. following injection would appear similar to that observed by Ansell and Dohmen[2]. Afterwards, the curves follow different courses. It might be pointed out here that in the original paper of Ansell and Dohmen[2] the phosphatidic acid is referred to as an 'unknown phospholipid' yielding glycerophosphate on mild alkaline hydrolysis, because of the doubt then existing about the presence of phosphatidic acid as an *in vivo* component of tissues. Meanwhile, Hokin and Hokin[14] have resolved this problem and have shown that phosphatidic acid is present in brain tissue, though their results suggest that its uptake of phosphorus-32 over a short interval *in vivo* is slower than we have found. Hübscher and Clark have also unequivocally obtained a phosphatidic acid from liver[15].

It is, however, admittedly difficult to make comparisons when animals of different ages are involved. For the rat *in vitro*[16] and for the rat and mouse *in vivo*[1,17] it has been shown that the capacity of the brain to incorporate orthophosphate into phospholipids declines rapidly from birth to early maturity; thereafter the rate decreases much less sharply. Recent experiments have shown that brain sphingomyelin incorporates radioactive phosphate much more rapidly in the myelinating rat brain than in the older brain when myelin is not being so actively formed[18]. It is apparent, in fact, as might be expected, that the rate of replacement of the phosphate moiety of brain phospholipids varies with age and with the phospholipid under consideration.

METABOLISM OF POLYPORES WITH PHOSPHORUS-32

By PROF. S. R. BOSE* and P. BONET-MAURY*

Kar Medical College, Calcutta

IN these studies, our object is to trace the migration of phosphorus-32 from the host-plant to the fungus as well as its migration from the surface of the fruit-body of the fungus to its hymenial layer by direct application on the upper surface of the fruit-body. No such study has been carried out with higher fungi, so far as can be ascertained from published reports. Recently, Grossbard[1] discussed autoradiography in the metabolism of fungi, showing its application in the physiology of some fungi (mostly lower) and pointing out its future usefulness in mycology and plant pathology.

Phosphorus-32 has been one of the most widely used radioisotopes on account of the biological importance of the element, as it is well known that phosphorus enters into the constitution of protoplasm, of phospholipids, phosphoproteides, amino-acids, and neucleoproteides (cellular metabolism); moreover, phosphorus-32 can be easily produced, it has convenient half-life (14·3 days) and it emits energetic β-rays.

We first followed absorption of phosphorus-32 by *Fomes* (*Polyporus*) *lignosus*. *F. lignosus* is usually known as a common root disease-fungus. Its habitat, distribution, morphology and cultural characters have been fully described by one of us[2].

We adopted two concentrations of phosphorus-32 (solution of phosphorus-32 without carrier in neutral solution of sodium phosphate (*p*H 7) prepared by C.E.A. in sterilized vessels) for our study; 5 μc. and 50 μc. per litre; this activity is sufficiently low as not to disturb the metabolism of the fungi, and with this it is convenient to have reasonably accurate radioactivity measurement. Fresh carrot roots were surface-sterilized with calcium hypochlorite (200° chlorometric per kgm.) for 1½ hr., then washed thoroughly with four or five changes of sterilized water at intervals of 20 min. in order to eliminate the toxic matter completely. The outer surface (peripheral tissues) of such roots, which turned white and translucent due to the treatment, was rejected. They were cut aseptically into pieces of 3–4 cm. in length and put (leaf-side up and root-side down) inside sterilized Roux tubes, constricted ends of which contained Gautheret's[3] liquid medium supplemented with phosphorus-32 (sodium phosphate) of the above two doses; each Roux tube contained one piece of the carrot, and the lower end of each piece was kept dipped in the liquid medium for direct absorption of phosphorus-32. A large number of Roux tubes was thus prepared for tissue culture of carrot root, and after an interval of 15 days, when there was good absorption of phosphorus-32 by the carrot according to the Geiger–Müller count (in many cases there was a small growth of new tissue (callus) at the cut surface of carrot pieces), the Roux tubes containing the carrot pieces were exposed to a constant temperature of 60° C. for 20–30 min. After cooling, each carrot piece was inoculated with a very young hyphal culture of *F. lignosus*, the inoculum being approximately equal in all cases. The fungus (a weak parasite) does not grow easily on living mature carrot roots on account of the tissue-resistance, though it kills at once very young tissue cultures; but it has been found that, if the resistance is lowered by exposure to 60° C. for about half an hour, the fungus makes a vigorous growth (Fig. 1) in the course of two or three days. Now, after an interval of 8–10 days, the measurements of activity of the fungus and of carrot pieces were taken; the activity of the fungus growing on carrot with concentration of 50 μc. and 5 μc. per l. was distinct; detailed results are given in Table 1*a*. This is an example of two techniques together: the technique of tissue-culture of carrot and that of radioisotope of phosphorus-32.

We then studied absorption of phosphorus-32 from solid medium with 1 per cent agar in Petri plates in Gautheret's medium, to which two doses of 5 μc.

(*c*) Activity of spore-slides of *Ganoderma applanatus* var. *australis*.		
Sporophore *A* (mean of 22 slides)	9·6	counts/min./slide.
Sporophore *B* (mean of 15 slides)	29·2	,,
(*d*) Activity of sporophore-tissues of *G. applanatus* var. *australis*.		
Sporophore *B* context area	24·2	counts/min./cm.^{2}
Sporophore *B* porous area	83·7	,,
Sporophore *C* total area	102	,,

per l. and 50 μc. per l. of phosphorus-32 were added, it being solidified with 1 per cent agar; 10 c.c. of the medium was poured on 9 cm. plates, which were autoclaved, and circular sheets of sterilized 'Cellophane' paper and filter paper equal in diameter to that of the bottom half of a Petri dish were aseptically placed on the surface of the medium, one to each plate. Equal pieces of inocula from the growing edge of a very young plate culture of *F. lignosus* aseptically cut with a cork borer of 8 mm. diameter, were placed on the paper in the plates. After allowing the fungus to grow and absorb phosphorus-32 for 12–20 days, the absorption of the isotope by the fungus at different dates within the interval was measured from the specific activity of the samples according to Geiger–Müller count. The absorption was found significant and that by the bare filter paper was much less than the absorption by the fungal hyphæ; detailed results are given in Table 1*b*.

More interesting results were obtained by application of phosphorus-32 to an intact plant (a *Tilia* tree growing in the compound of the Château de Gif at the Centre National de la Recherche Scientifique) which bore nine small fruit bodies of *Ganoderma applanatus* var. *australis* on the body of the trunk within a length of about 4 ft. above ground-level (Fig. 2 marked with arrows). Scott Russell[4] holds the appearance of radioactivity in shoots of intact plants can provide unequivocal evidence of active transport. Tukey[5] has shown that radioactive minerals entered even through the bark of fruit trees (apple and peach) quickly, and that within 24 hr. of application, radioactivity was detected within the dormant branches, 18–24 in. above and below the points of application, even during winter with temperatures below freezing point.

On July 11, 1958, two square holes (2 cm.^{2}) were drilled in the bark of the trunk of the above-mentioned living tree (*Tilia* sp.) at a height of about 4 ft. from its base, just above and below a sporophore (*A*) of *G. applanatus* var. *australis*, and two cotton pads (2 cm.^{2}) soaked with 2 c.c. of phosphorus-32 (dose being 100 μc. per 2 c.c.), were inserted into the holes, one to each hole; now a number of slides smeared with glycerine were placed below the sporophore on a thick 'Cellophane' platform to catch the falling spores which were being shot out copiously and continuously day and night from the beginning of July, and the whole was very carefully covered with 'Cellophane' paper to keep out external draught or rain. Another cotton pad similarly soaked with phosphorus-32 of the same dose was placed on the top surface of another sporophore (*B*) on the same trunk, and slides (smeared with glycerine) were placed beneath the sporophore, the whole being similarly covered with 'Cellophane' paper. An adjacent sporophore (*C*) just 4 in. below the sporophore (*A*), to which no phosphorus-32 was applied in any way, was kept for observation with slides beneath the sporophore to catch the spore-fall. After an interval of 4 days, slides with copious spore-deposits from the three sporophores *A*, *B* and *C*, as well as fragments of three fruit bodies with porous areas, were taken out for measurement of radioactivity. In each case of the spore-slides and pieces of sporophore the activity was significant, and shot-out spores were distinctly radioactive, while spore-deposit from the same fungus taken two weeks before the application of phosphorus-32 to the trunk showed no radioactivity; detailed results are given in Table 1*c*. The porous areas were more radioactive than the context areas (Table 1*d*). The radioactivity of the sporophore *C*, to which there was no application of phosphorus-32, goes to show that there was active transport of phosphorus-32 in the body of the tree as remarked by Tukey.

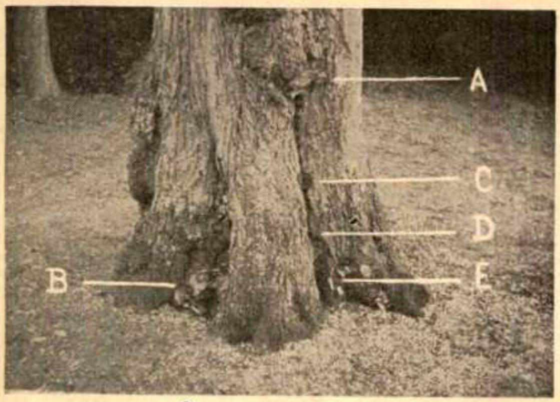

Fig. 2

On October 2, 1958, at 11 a.m., a second higher dose of 1 mc. per 2 c.c. of phosphorus-32 was injected into the top hole only of sporophore *A* (*G. applanatus* var. *australis* growing on the same *Tilia* tree at the Château de Gif), and a 2 per cent agar opened (cover taken out) plate and 10 aluminium cupules were aseptically placed underneath the sporophore at 3 p.m. Geiger–Müller counting after 20 hr. showed that spores were positively radioactive of the order of the background. Before this second injection, spore-fall of *G. applanatus* var. *australis* on slides smeared with glycerine was taken for 24 hr. during September 14–15, 1958; such spores, when tested, were found to be not radioactive. This occurred after an interval of two months and four days from the first injection. Spore-fall from the sporophore *A*, which was radioactive, occurred only once, on October 3; and it entirely stopped thereafter, that is, one month earlier than the normal time, whereas the spore-fall from the sporophore *B* (which was not radioactive) on the same tree continued up to November 6. Germination of spores which were not

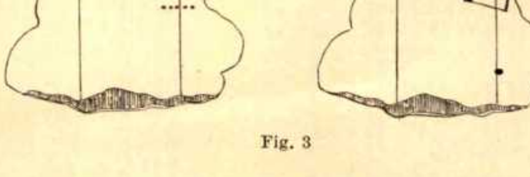

Fig. 3

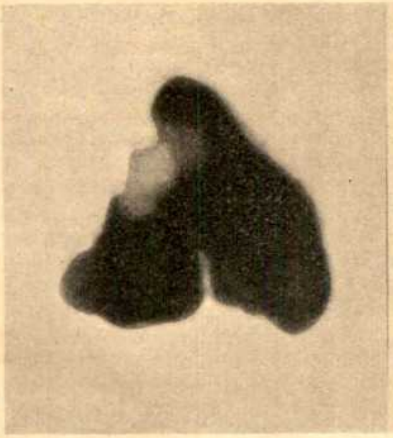

Fig. 4. *D*1. 10 min. exposure

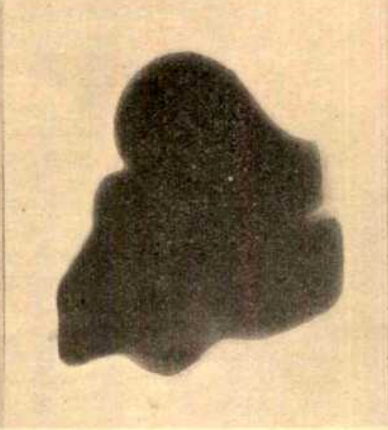

Fig. 5. *D*2. 10 min. exposure

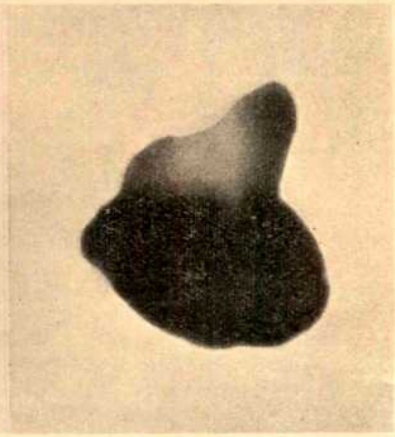

Fig. 6. *E*2. 10 min. exposure

radioactive, in malt-agar tubes, was quite easy; they germinated in the course of 10 days, whereas germination of radioactive spores took place only once, after an interval of 20 days, and in one malt agar tube only out of ten such tubes; but cultures of these radioactive spores in malt agar plates showed no trace of radioactivity. Moreover, from examination of colour change of the hymenial surface of the sporophore *A* from a whitish to a brownish colour after October 3, it appears that it had then stopped throwing out spores (Bose[6]). It was further noted that subcultures of radioactive spores in malt agar plates in the dark at 24° C. (incubator) grew perceptibly more slowly than those of normal non-radioactive spores of *G. applanatus* var. *australis*; the diameter of 10 days growth of the mycelial mat in malt agar plates was only 6 cm. in the case of radioactive spore-hyphæ, whereas in the case of non-radioactive spore-hyphæ the diameter of growth under identical conditions was 8·5 cm. on the average. But detailed examination of the growth of the two mycelial mats under the microscope showed no difference whatsoever in characters of the hyphæ; thus the noted difference in rate of growth may be purely cytoplasmic, as indicated by Jinks[7]. Consequently, it may be held that radioactive spores of *G. applanatus* var. *australis* are susceptible to radiation.

Microscopical examination of the surface of the hymen of normal sporophores showed that, by November 1958, they were past the sporing stage, basidia being almost entirely replaced by tramal hyphæ—elongations which rapidly fill up the pores—and *Ganoderma* spores are no longer found in sections of sporophores.

On December 12, two sporophores (*D* and *E*) of *G. applanatus* var. *australis* growing on the same *Tilia* tree at Gif Château were treated with phosphorus-32, the dose being 1 mc./c.c. in each case. In the case of sporophore *D* the very tough upper surface was scratched to a depth of 1 cm., and a cotton pad soaked with 1 c.c. of phosphorus-32 was placed directly on the scratched surface, while in the case of sporophore *E*, the upper surface was injected with a tuberculin syringe, 1 cm. deep, 1 c.c. of phosphorus-32 being divided into four injections of equal quantity of the liquid. Both the sporophores, *D* and *E*, were very carefully covered with 'Cellophane' and brown paper for protection against the prevailing light showers of rain and occasional gusts of wind. After an interval of four and a half days, each of the two sporophores (*D* and *E*) was cut longitudinally at two spots—one corresponding to the treated areas (*D*1 and *E*1), and the other, distant areas (*D*2 and *E*2); so, they were marked respectively as *D*1 and *D*2 and *E*1 and *E*2 (Fig. 3).

These four pieces were then autoradiographed at Saclay, Service de Biologie du Centre d'Etudes nucleaires, following closely the method of Pellerin[8]. The injection method was not quite satisfactory on account of suspected leakage from the needle-end pressing against the very tough surface of the sporophore, but in the distant area, *E*2 (Fig. 6), there was a clear indication of accumulation of phosphorus-32 towards the hymenial surface. The specimen-pieces were highly radioactive according to Geiger–Müller count—*D*1 giving 49,000 counts per min. per gm., and *D*2 giving 45,000 counts/min./gm.

An exposure of 10 min. to X-ray film in the dark with liquid nitrogen at – 200° C. was sufficient to bring out distinct images (Figs. 4, 5 and 6). It can be seen that heavy accumulation of phosphorus-32 takes place towards the hymenial (porous) surface. There is thus clear evidence of ready transport of phosphorus-32 to the most active area, full of living cells. Control (a longitudinal section of a normal sporophore) under identical conditions showed a perfectly blank area.

One of us (S. R. B.) is grateful to the Centre National de la Recherche Scientifique, Paris, for a research grant for this work and to the authorities of the Institut du Radium (Laboratoire Curie) for facilities for this work, and we thank M. D. Basu working at Saclay (C.E.A.) for help with a portion of this work with tree injection and with part of the Geiger–Müller counting. For the mycological work one of us (S. R. B.) is indebted to Prof. R. Heim for facilities accorded in the Laboratoire de Cryptogamie, Muséum National d'Histoire Naturelle, Paris.

LETTERS TO THE EDITORS

PHYSICS

Film Transfer in He II

During the course of experiments on film transfer in very narrow beakers and in vessels with very narrow apertures, phenomena have appeared which are difficult to reconcile with the existing interpretation of the nature of film transfer and of critical velocity[1].

It has been found, especially at temperatures in the neighbourhood of 1·3° K. where most of the measurements have been made, that the rate of transfer out of a narrow cylindrical beaker of, say, 1·5 mm. diameter is dependent on the history and condition of the liquid in the beaker and is no longer the characteristic rate of transfer per cm. width of surface at the temperature in question. Eselson and Laserev[2] observed a similar effect some years ago, but were unable then to offer an explanation. The present results are in agreement with their work and extend it in several ways. Recently, Snyder and Donnelly[3], describing film transfer from rotating vessels, also mention one or two instances of a similar effect.

For the experiments reported here a cylindrical beaker was used, 5 cm. long and of inner diameter 1·8 mm. and outer diameter 3·6 mm. The rim of the vessel was ground concave conically so as to give clearly defined outer and inner perimeters. A typical experiment consisted first of filling the beaker—either by plunging it beneath the bath or by allowing it to fill by film transfer—and then of observing a sequence of emptyings and fillings by film transfer alone, over a range of 4–15 mm. below the rim of the beaker. Table 1 shows the results of such an experiment. Sequence *A* was initiated by plunging the beaker and then withdrawing it; sequence *B* was initiated by emptying the beaker completely after *A* and then filling solely by the film; and finally, sequence *C* was initiated by a further plunge-fill of the beaker.

From this and similar experiments with other vessels the following general features were observed: (*a*) following a plunge-fill, the rate of emptying was higher than it was after a film-fill, the maximum observed difference between the two rates for the same beaker being nearly 70 per cent; (*b*) rates of filling were always lower than rates of emptying, the difference being to some extent dependent on the wall thickness; (*c*) for the same vessel, rates of emptying after successive plunge-fills differed from each other, sometimes by as much as 15 per cent; (*d*) a pause of 20 min. between a plunge-fill and subsequent emptying had no observable effect of reducing the fast rate of emptying.

Table 1

Sequence	Transfer-rate on emptying (cm.^{2} sec.$^{-1}$ × 10^5)	Transfer-rate on filling (cm.^{2} sec.$^{-1}$ × 10^5)
A (Plunge fill)		
Emptying	13·2	
Filling		6·87
Emptying	9·02	
Filling		6·82
Emptying	9·17	
B (Film fill)		
Filling		6·90
Emptying	8·57	
Filling		6·70
Emptying	9·47	
C (Plunge fill)		
Emptying	14·2	
Filling		6·42

It was inferred that the fast rate of emptying by the film following a plunge-fill drained off the excess of something which had been introduced by the plunge, and that this excess might be turbulence. This inference was tested in a separate experiment in which a small solenoid-activated iron wire stirrer was put into a beaker. It was observed that continuous stirring during emptying increased the rate of emptying by 10 per cent over the unstirred rate, while continuous stirring during filling reduced the normal filling rate by about 10 per cent. Although the reduction in filling rate was remarkable, the increase in emptying rate caused by stirring the beaker was not as great as the increase obtained by a plunge-fill, which might indicate that stirring is not an efficient way of making turbulence in so nearly an ideal fluid.

It has been assumed that there exists a 'critical' rate of film transfer, although its precise value has been a matter of some disagreement. Hence, knowing the thickness of the film one can determine a 'critical' velocity. From earlier experiments it has been inferred that when the velocity is less than 'critical' the liquid in the film moves without friction, but that at or a very little above the 'critical' velocity the friction becomes great and the energy is dissipated in the creation of excitations.

It is difficult to reconcile the notion of 'critical' velocity with the experiments that are reported here, and we may therefore be forced to abandon it. If so, it could be replaced by one in which the movement of the film is intimately associated with turbulence. Suppose, for example, that the film moves, as it were, on line vortex roller bearings, and that if no such vortices are present in the film then no motion of the film occurs. If this is so, then one might expect that the more vorticity there is available at the source of the film the more liquid will be transferred by the film, whereas if vorticity is scarce at the source then the rate of transfer will be lowered. Excess of turbulence at the downstream end of the film also appears to slow the transfer, which might indicate either that turbulence is flowing both ways in any film so that the transfer is a net transfer, or that the specific quantity of turbulence in a vessel has an appreciable chemical potential.

The picture, although it is obviously very crude, does not appear to be in conflict with earlier experiments on film transfer, and it may also have relevance for the concept of critical velocities in the bulk liquid. A so-called 'critical' velocity might cease to be the upper limit of velocity before the onset of friction, and become a velocity which depends on the energy required to produce the amount of vorticity involved in the flow.

This kind of vorticity or turbulence is very long-lived; in the example quoted earlier it appeared to remain more or less intact for at least 20 min. in a volume of about 0·1 cm.[3]. The conversion of such vorticity into rotons, which was envisaged by Feynman[4], seems therefore to be a very slow process indeed.

In the particular case of film transfer one is involved in discovering the particular properties of line vortices running along close to a wall, and also whether in the film which covers the surface of a tube the vortices form closed rings or a continuous helix with one end fixed in the bath and the other in the beaker.

These results, together with others made with vessels with very narrow necks or with matt surfaces, will be more fully discussed in a later paper.

In conclusion, I wish to record my thanks to Dr. C. G. Kuper for much fruitful collaboration, and also to Dr. D. V. Osborne and Dr. D. Bohm for stimulating discussion.

Mechanism of Superfluid Flow

Theories of superfluidity usually assume the possibility of pure potential flow, provided that the flow velocity is less than some critical value (at which the creation of excitations first becomes possible)[1,2]. If we consider the flow of helium (at $T = 0°$ K.), for example through a tube or along a Rollin film, it is implied that the boundary layer is slipping over the solid wall. However, the first few layers of helium atoms would not be expected to take part in this motion, as they are firmly bound by the van der Waals' attractions of the wall. The picture therefore has to be revised slightly to one in which there is a velocity discontinuity (that is, a vortex sheet) close to, but not coincident with, the solid wall. But a continuous vortex sheet implies a rather drastic change in the character of the wave function, over a distance of the order of one interatomic distance a, and hence implies a large energy per unit area, of the order of $\hbar^2/ma^4$ (where m is the mass of an atom).

A more realistic model for helium, flowing at $T = 0°$ K., would seem to be one in which the vortex sheet is replaced by some sort of array of Onsager–Feynman quantized vortex lines. For example, a Kármán row of unit quantized vortices[3] will be able to reproduce the macroscopic features of the 'vortex sheet' model for flow parallel to a plane wall; the vortices will themselves take part in the motion. The liquid in contact with the wall should have zero average velocity and reasonably small actual instantaneous velocity.

Let us consider a row of vortex lines of strength $\varkappa = 2\pi\hbar/m$, perpendicular to the plane of the paper, cutting it at the points (na, b), and let the solid surface be the plane $y = 0$ (Fig. 1). Then, if the vortices are at rest, the x and y components of the velocity are given by the real and imaginary parts respectively of[3]:

$$-i\pi\varkappa a^{-1}\cot\{\pi a^{-1}(x + i(y - b))\} \qquad (1)$$

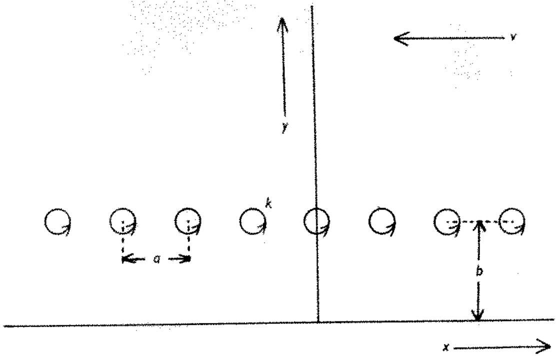

Fig. 1

If $a \ll b$, this pattern approximates to a vortex sheet, and the oscillatory part of the velocity is very small except very near the vortex row; indeed, even if a is fairly comparable to b, provided only $\exp(-b/a) \ll 1$ holds, the periodic fluctuations of velocity at the wall remain small compared to the zero-point velocities of helium atoms. The mean velocity on a plane parallel to the wall is:

$$-\pi\varkappa a^{-1}\tanh\{\pi(y - b)/a\} \qquad (2)$$

and is in the x-direction. The boundary layer can be brought to rest, on the average, by superimposing a velocity:

$$-\pi\varkappa a^{-1}\tanh(\pi b/a) \qquad (3)$$

on the fluid (and in particular on the vortex lines). The magnitude of the macroscopic velocity of flow is then:

$$V = 2\pi\varkappa a = 4\pi^2\hbar/ma \qquad (4)$$

provided $b \gg a$, and the depth of liquid $\gg b$.

In a Rollin film of thickness t, if $a \gg t$, flow by this mechanism cannot proceed—there are not enough vortices to serve as 'bearings' (Allen, J. F., previous communication). Hence a film cannot flow steadily unless $a \lesssim t$, when:

$$V \gtrsim 4\pi^2\hbar/mt \qquad (5)$$

Thus, instead of a 'critical' velocity, h/mt plays the part of a minimum flow velocity[4]. Any higher velocity is possible, but in general energy will have to be supplied to replace the vortex lines carried away by the flow. For the occurrence of lower velocities, a more complicated configuration of vortices will be needed, which will probably lead to increased dissipation. Some instability of flow might also be expected near the velocity (5).

Allen has suggested that his experimental results should be interpreted as showing that a Rollin film flows by 'rolling' on vortices. The microscopic arguments advanced here lead to just this picture of the flow. Older experiments, which appear to support the idea of a critical velocity, require re-interpretation. The present suggestion is that there is a velocity of minimum energy dissipation—the velocity which is normally observed in steady flow. It should be noted that a persistent current around a torus remains possible, since vortex rings can just roll round the torus.

The actual geometrical array of vortices is likely to be more complicated than I have envisaged here. The energy of interaction between two vortex lines is quite comparable to Feynman's[2] self-energy of one line, so that quantitative calculations become difficult. The mutual repulsions between like parallel vortices will probably tend to give a fairly uniform lattice of lines, rather than just a row.

I am greatly indebted to Prof. J. F. Allen for many discussions during the progress of his experiments and wish also to thank Dr. D. Bohm and Dr. O. Penrose for stimulating discussions.

Measurements of the Frequency of an Ammonia Maser in England and Australia

THIS communication describes preliminary measurements of the oscillation frequency of the Signals Research and Development Establishment Maser No. 5 at the National Physical Laboratory, Teddington (by the Standards Division), and afterwards at the Research Laboratories of the Australian Post Office in Melbourne, Australia. Maser No. 5 is a rack-mounted experimental maser with continuous pumping and employs unpurified commercial anhydrous ammonia. An eight-pole state separator is used together with a silver-plated brass microwave cavity operating in the TM_{010} mode. The cavity is thermally tuned to the (3,3) transition. A more detailed description of this maser may be found elsewhere[1].

The maser was operated at the National Physical Laboratory under the following conditions: Ammonia gun pressure 1·0 mm. mercury (corresponding to a total flow into the system of 3×10^{17} mole./s.) and 18 kV. d.c. between adjacent poles of the state separator. The resonant frequency of the cavity was adjusted thermally to a value such that the maser oscillation frequency changed less than 2 parts in 10^{10} when the gun pressure was changed from 0·5–1·0 mm. mercury. This was one of several possible methods of establishing a resettable oscillation frequency. Other methods give different oscillation frequencies[1,2], none of which necessarily corresponds to the emission line frequency. The oscillation frequency was measured in terms of a local 5 Mc./s. quartz standard which in turn was calibrated against the cæsium resonator[3]. Results are shown in Table 1 (sets 1 and 2), the absolute accuracy of the National Physical Laboratory measurements being ± 2 parts in 10^{10}. After completion of set 1 the state separator and ammonia gun assembly were removed and the wave-guide connexion to the cavity uncoupled. This was an attempt to simulate the dismantling required prior to shipment of the maser by sea to Melbourne. After re-assembly the maser frequency was remeasured with the results shown as set 2. The downward shift in frequency of 1·3 parts in 10^9 is significant but time did not permit investigation of the reason.

The maser was then dismantled, shipped to Melbourne and installed at the Australian Post Office Research Laboratories. Certain improvements were made to the thermostat controlling the microwave cavity temperature and the cavity frequency again adjusted so that the maser oscillation frequency was independent of gun pressure changes between 0·5 and 1·0 mm. mercury. As before, the gun pressure was maintained at 1·0 mm. mercury and the separator voltage at 18 kV. d.c., while measurements of oscillation frequency were made in terms of a local 100 kc./s. quartz standard. The results are shown as sets 3–8, the spread of measurements within a set (col. 6) being slightly inferior to that obtained at the National Physical Laboratory. The frequency of the local quartz standard was measured by comparing it with the G.B.R. transmission from Rugby using a beat frequency method. Because of the poor signal-to-noise ratio of the received signal it was necessary to average the beats between G.B.R. and the local standard over a period of 22 hr. each day to obtain an accuracy of ± 4 parts in 10^{10}. However, an additional but unknown error of perhaps several parts in 10^9 must also be added due to propagation variations over the path Rugby–Melbourne. After applying the National Physical Laboratory corrections to the oscillator controlling G.B.R., the mean maser frequencies shown in sets 3–8 are obtained. The grand average of all the Melbourne results is 2·2 parts in 10^9 higher than the average of the National Physical Laboratory results. As stated above, this frequency difference is comparable to the propagation error which must be attached to the Melbourne mean frequencies given in Table 1.

Some evidence has been obtained to show that the frequency of oscillation is dependent on the ambient temperature to the extent of −1 part in 10^{10}/deg. C. rise. This is almost certainly due to inadequacy of the thermostat controlling the cavity temperature. The effect can be seen in sets 6, 7 and 8. The ambient temperature was rising throughout November 11, 1959, and was higher during measurements on November 12, 1959. Further work is being carried out both at the Signals Research and Development Establishment and the Australian Post Office Research Laboratories, Melbourne, towards discovering and controlling the residual factors governing the maser oscillation frequency. For comparison pur-

poses we have appended to Table 1 the published frequency[4] for an ammonia maser employed at Laboratoire Suisse de Recherches Horlogères, Neuchâtel, using another re-setting criterion. The frequency of this maser is considerably lower than that of Maser No. 5 and illustrates the fact that it is possible to operate ammonia masers with considerably different but yet highly stable oscillation frequencies.

We wish to thank the Director of the National Physical Laboratory for making available the results of the maser/cæsium comparisons obtained at Teddington. Monocular 'Rivalry' between Stabilized and Unstabilized Retinal Images

IT is well known that images stabilized against retinal tremor tend to fade from vision[1,2], and it has been suggested that this indicates some form of fatigue or adaptation in the retinal receptors, which is normally relieved by small irregular displacements of the image. When using a simple stabilizing device[3] for the study of complementary patterns[4], I have observed a related effect which seems to require further, if not different, explanation.

The apparatus[3] comprises a close-fitting contact lens with an optical power of 60 dioptres, supporting a light 'Dural' tube on which objects under examination are mounted at the focal distance of about 1½ cm. The lens incorporates an artificial pupil 4 mm. in diameter. When the image of a sharply black-and-white object such as my 'ray' figure[4] is thus stabilized on the retina, fading is much less pronounced and permanent than with more delicate and irregular gradations of stimulus intensity[2].

The observation in question is as follows. When a thin object, such as a wire the diameter of which subtends perhaps 10′, is viewed in silhouette, it often remains visible for some time. If, however, an object giving an unstabilized image, such as the finger-tip, is now brought up just behind the wire to the focal zone of the stabilizing lens, a striking change takes place. The stabilized wire disappears as a whole, and the finger-tip appears completely visible, as if nothing were between it and the eye. The impression is similar to that given by binocular rivalry between disparate images in left and right eyes. When the finger is removed, the wire reappears.

With stabilized objects of increasing width, it is necessary (as might be expected) to scan the unstabilized background with an increasing amplitude if the objects are to disappear from view, and a limit is reached (dependent partly on the structure of the background) beyond which total disappearance does not occur.

It may well be suspected that the reluctance of the wire (and indeed of the 'ray' figure) to disappear permanently when stabilized is due in part to imperfect stabilization. This I leave an open question, though it may be remarked that with apparatus which presents the stabilized image within an unstabilized frame[1,2] it would now seem unsafe to use extinction of the image as a criterion of stability. What seems significant is that one can cause the disappearance—sudden and complete—of a thin stabilized object merely by presenting it against an unstabilized background. Together with the inhibition of extinction by regularity and boldness in the stabilized pattern this raises doubts whether changes in retinal receptors alone are responsible for the normal fading. On a retinal theory one might have expected that the addition of an unstabilized background would revive activity in neighbouring receptors adapted to a stable image by disturbing them, as flickering light is found to do[5].

It is difficult to see how it could predict the opposite effect actually observed, particularly the simultaneous and sudden disappearance of all parts of the wire. For this the idea of fatigue or adaptation among primitive gestalt-forming mechanisms would seem worthy of exploration.

GEOPHYSICS and GEOLOGY

Palæomagnetism in Antarctica

WE have recently measured the direction of magnetization of two dolerite sheets and ten basic dykes in the Wright Valley (lat. 77·5° S., long. 161·5° E.) of South Victoria Land. The dykes intrude the basement granite in the area but do not cut the overlying Beacon Sandstone. The dolerite sheets are intruded into the basement and in some places cut the Beacon Sandstone. They post-date the dykes and the sandstone. The directions and relevant statistics are given in Table 1.

There is good evidence that the directions of magnetization are stable. The divergences of the mean directions of both sheets and dykes from the present Earth's field and the dipole field exceed the errors ($P = 0{\cdot}05$) by a factor of 3 or more. The coercivity of saturation isothermal remanence is high, varying from 600 to 1,200 œrsteds. Treatment in alternating magnetic fields of up to 370 œrsteds (peak) produced only small changes in the directions of magnetization. In some cases the directions remained little changed in alternating fields up to 750 œrsteds. These changes vary between 2° and 5° and are of the same order as the experimental error.

Other pole results from Antarctica have recently been reported by Nagata and Shimizu[1] from the Pre-Cambrian gneiss of Ongul Island (namely, lat. 3° N.,

Table 1. MEAN DIRECTIONS OF MAGNETIZATION AND POLE POSITIONS

Geological unit	N	n	s	Mean direction of magnetization				Pole position				Divergences	
				D	I	R	α	Latitude	Longitude	$\delta\psi$	$\delta\chi$	$\triangle F$	$\triangle P$
Dolerite sills	8	11	20	262	−70	7·889	7	51° S.	132° W.	10	12	23	21
Basic dykes in grey granite	10	14	31	237	−56	9·832	7	29° S.	149° W.	7	10	32	38

N denotes the number of sites, n is the number of samples collected and s is the number of specimens cut from these samples. D and I are the declination and inclination of the resultant direction of magnetization computed by giving each site unit weight. R is the length of the resultant, α is the error of the mean at $P = 0{\cdot}05$ (Fisher, ref. 4), and $\triangle F$ and $\triangle P$ are the divergences of the mean direction from the present Earth's field (155°, −83°) and from the dipole field (0°, −84°) respectively. The pole positions in the southern hemisphere are specified by latitude and longitude and the errors $\delta\psi$ and $\delta\chi$ are in the direction of and at right-angles to the co-latitude, respectively.

long. 107° W.), by Turnbull[2] from the Cainozoic volcanics of Cape Hallett (lat. 81° S., long. 94° E.), dolerite sills of the Ferrar Glacier (lat. 58° S., long. 142° W.) and from the Beacon Sandstone (lat. 53° S., long. 151° W.), and by Blundell and Stephenson[3] from some dolerites from Theron Mountains and Whichaway Nunataks (lat. 54° S., long. 136° W.). These poles, together with those calculated from our results, are plotted in Fig. 1. The results from the dolerites are in good agreement. Turnbull is of the opinion that the Beacon Sandstone he sampled may have been reheated by the dolerite, which thus accounts for the agreement of the result from the Sandstone with the dolerites.

The precise geological age of these rock formations is not known. The basement dykes could be Palæozoic, the Beacon Sandstones are probably for the most part Upper Palæozoic or Early Mesozoic, and the dolerites are very likely to be Mesozoic in age. However, except for 4C, about the age of which little can be said, the relative age sequence is almost certainly that given in Fig. 1. The following general points may therefore be made.

(1) The divergence of the palæomagnetic pole from the present geographical pole increases with geological age. In geological recent times it is in the vicinity of the present pole and in the Pre-Cambrian it is near the present-day equator (see ref. 1 for discussion of the latter point).

(2) The poles have characteristic longitudes between 100° and 150° W. In these two features the results are similar to the pole paths obtained from Europe, North America, India and Australia.

(3) However, the longitudes differ very greatly (in some cases by 100° or more) from the longitudes of the poles obtained from these four regions. This result emphasizes for yet another continent the divergence that occurs between results from different continents for periods prior to the Tertiary.

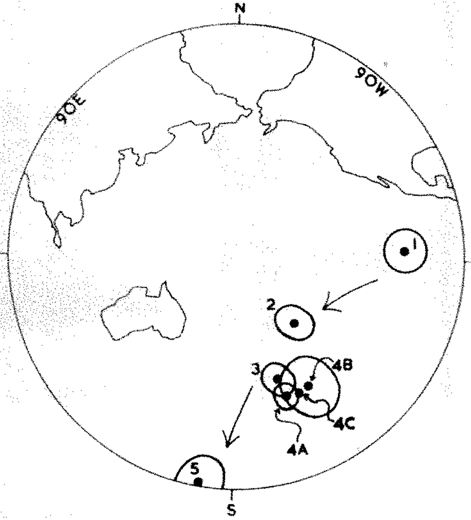

Fig. 1. Pole positions from Antarctica. The pole positions are numbered as follows: 1, Ongul Island gneiss; 2, basement dykes; 3, Beacon Sandstone; 4A, dolerite sills, Ferrar Glacier; 4B, dolerite sheets of Wright Valley; 4C, Theron and Whichaway dolerites; 5, Hallett Cove volcanics. The projection is equatorial stereographic

Infra-Red Determination of the Kaolin Group Minerals

BY infra-red absorption analysis, it is possible to make a semi-quantitative estimation of the kaolin minerals. In contrast to X-ray diffraction, the infra-red spectrum of halloysite is as clearly defined as those of kaolinite and dickite, and the content of these three minerals in mixtures can be determined by a ratio between the depths of their hydroxyl absorptions. The peaks at 2·70μ (A) and 2·75μ (B) are common to all three minerals, and a peak depth ratio A/B of 1·2–1·5 is characteristic of kaolinite, with a ratio A/B of 0·8–0·9 characterizing halloysite. Values of 0·6–0·8 are typical of dickite. If the depth of the band due to physically adsorbed water at 2·9μ (C) is plotted as the abscissa with A/B as the ordinate, the three minerals fall into separate areas.

Examination of the spectra due to Si–O and Al–Si–O between 8·9 and 10·1μ show a diagnostic pair of doublets. The doublet at 10·7μ (D) and 11·0μ (E) is typical of the Al–O–OH bonding of kaolinite and dickite, although only the single peak at 11·0μ appears for halloysite. An inspection of the A/B ratio and the presence, or absence, of absorption (D) enables a unique distinction to be made between the three minerals. The A/B ratio remains constant during dehydration over several hours up to 450° C.

The absorption at 2·70μ (A) is found only in the kaolin group and in such simple structures as brucite. It is due to oxygen–hydrogen stretching frequencies associated with the hydroxyl ions, the oxygen and hydrogen atoms being in two symmetrical layers in

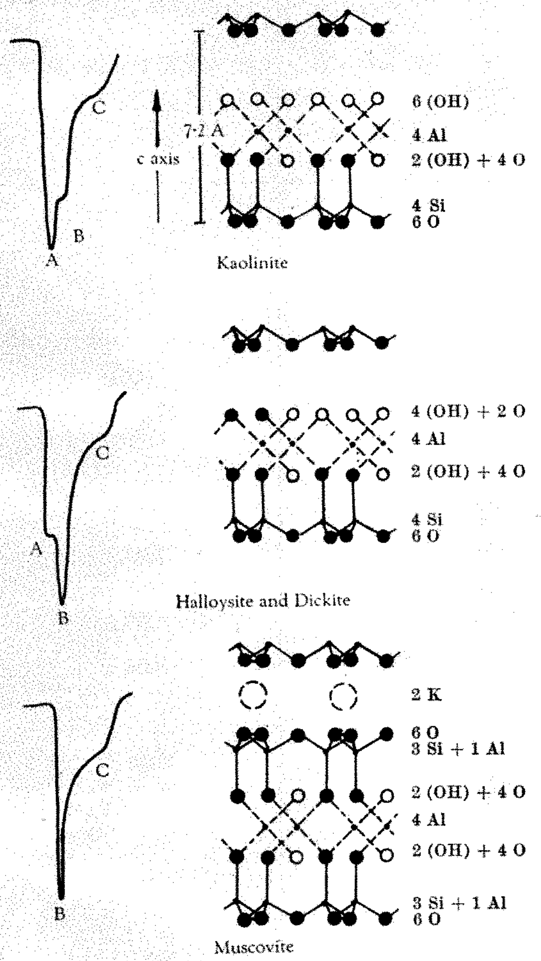

Fig. 1. Suggested oxygen–hydroxyl configuration for halloysite and dickite as compared with kaolinite and muscovite. Hydroxyl portions of their infra-red curves appear to the left of each structure

the brucite crystal. The 2·75μ (*B*) absorption is common to all micas and three-layer minerals, which differ from kaolinite in that their upper layer of oxygen–hydroxyls is only one-third hydroxyl, two-thirds oxygen.

A modification of the general kaolinite structure is proposed to explain the similarity in *A*/*B* ratio in halloysite and dickite as contrasted to that of kaolinite. The frequency of hydroxyls in the upper oxygen–hydroxyl level in the kaolin structure must vary between 3/3 (as in kaolinite) and 1/3 (as in the micas, when both upper and lower levels of the octahedral layer become symmetrical) (Fig. 1). Micas thus have a single (*B*) hydroxyl absorption. Kaolinite itself shows a full upper level of (*A*) type and full lower level of (*B*) type. Halloysite and dickite must lie at an intermediate value where 2/3 of the upper level are hydroxyls. This would decrease the strength of the (*A*) type absorption and increase the strength of the (*B*) type absorption, lowering the *A*/*B* ratio.

Aluminium–silicon substitution (*Y* number) in the basal, tetrahedrally co-ordinated levels of kaolinite, as proposed by Bates[1], should be very easy to determine in the same manner as used in the chlorite and other mica studies[2].

A more complete study on this subject will be presented at the forthcoming Pittsburgh Conference on Analytical Chemistry and Applied Spectroscopy in March 1960.

Sea-Level Fluctuations during the Past Four Thousand Years

Study of constructional details of a chenier plain along the coast of the Firth of Thames, New Zealand, together with radiocarbon dating of seven shell samples, has enabled the production of Fig. 1. Criteria used in interpreting the past sea-levels were (*a*) storm ridges, (*b*) high-spring-tide wash benches and (*c*) tidal stream flats. Often all three criteria could be used to determine one sea-level. Periods of sea-level highs correlate well with periods of transgression recorded along the European coast[1-3].

Tectonic movement, compaction and other causes could have led to misleading results; but their effects are considered small. Thus neglecting the minor fluctuations shown in Fig. 1, sea-level fell 7 ft. from 2000 B.C. to about the beginning of the Christian era and has remained relatively stable since. The present rise of sea-level is locally 8–9 in. per century and may well be only another minor fluctuation in an otherwise stable sea.

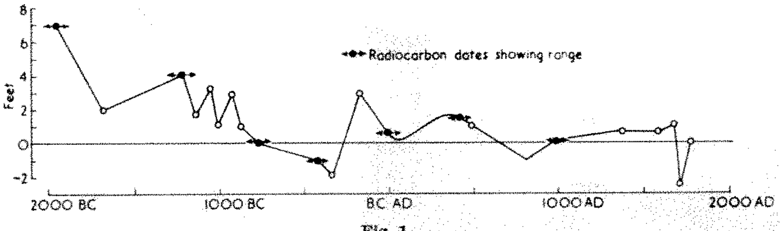

Fig. 1

Details will be published shortly in the *New Zealand Journal of Geology and Geophysics*.

Recognition of Folds and Faults on Rock Surfaces beneath the Sea

INFORMATION about the folding and faulting of the rock layers beneath the sea can be obtained by geophysical techniques, used in conjunction with sampling; but it is not easy to give a precise position of the geological boundaries on the floor, and only large faults can be inferred. The required detail can be obtained, however, by means of a geologists' asdic, where there are rock floors which consist of alternations of hard and soft beds and the former, being resistant to erosion, stand proud as ridges. In the English Channel, the Purbeck, Portland, Kimmeridge, Corallian beds and the ancient rocks occurring as shoals to east and west of Eddystone give good results, while Tertiary, Chalk and New Red Sandstone beds are too homogeneous to be suitable.

The method makes use of echo-sounding equipment, but instead of pointing the beam vertically beneath a ship it extends laterally and is tilted down and stabilized at about five degrees below the horizontal, so that echoes can be obtained from any ridges within a wide belt of floor parallel to the ship's course. The value of the method has already been described[1] and the equipment has been used on R.R.S. *Discovery II* to make reconnaisance surveys of sea-floors around southern Britain, with recent publication of some studies of sedimentary structures[2,3]. During these surveys rock outcrops of the type shown in Fig. 1 were found some miles south of the Dorset coast. The ship moved along a straight course (top of figure) covering two miles between the time marks, and examined a belt of sea-floor 800 yards wide, giving an exaggeration of scale of about four times for the range abeam. On this continuous plan view can be seen the dark bands of rock outcrops turning round in a gentle fold between the bottom right and left corners of the figure. In the upper part of the record a secondary beam which reached the sea floor beneath the ship gave a profile, in which an outcrop (black) terminates as a low cliff sloping away from the ship, at more than five degrees below the horizontal. The cliff marks the edge of a bed while the dip slope must be in the opposite direction and approximately at right angles to the line of outcrop of the bed. The continuity of any bed is interrupted by a parallel series of small faults, marked on the edge of the record with '*F–F*'. The pattern becomes increasingly blurred and vanishes as outcrops are progressively masked by loose sand at the right side of Fig. 1.

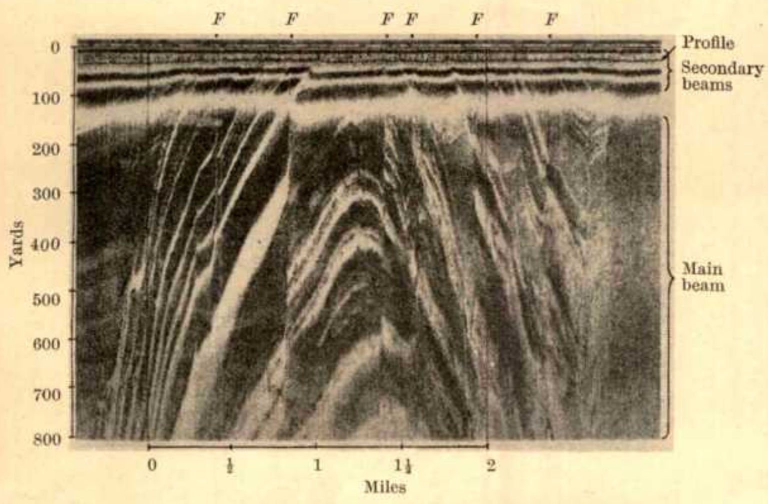

Fig. 1. A plan view of rock outcrops (black) on the sea floor showing part of a gentle fold and small fractures, '*F–F*'

A complete acoustic and sampling survey of this ground, off south-eastern Dorset, has since been made and an account, which is in preparation, will be published elsewhere with Dr. D. T. Donovan as co-author.

Dissolution of Silicate Rocks

IN work on the determination of trace elements in silicate rocks[1], an attempt has been made to solve the inherent difficulties of achieving a rapid and efficient dissolution of large samples (up to 200 gm.) of silicate rocks and at the same time ensuring that the minimum quantities of reagents are used.

The classical treatment of rocks involves dissolving the sample in a sulphuric/hydrofluoric acid mixture or a perchloric/hydrofluoric acid medium, the sample being contained in a platinum dish. There are several disadvantages inherent in the use of platinum ware for these operations, in particular the extremely high price of platinum apparatus which is slowly destroyed by fuming with sulphuric acid. A further serious objection is the fact that no determinations of any of the platinoids can obviously be carried out in such a container.

Since I have been concerned mainly with the determination of very rare elements in silicate rocks, appreciably large samples have had to be used (on the average about 20 gm.). The dissolution of much smaller quantities of rock (say 1 gm.) presents few difficulties[2] but clearly a special technique had to be employed for these larger samples.

The dissolution technique presented here is the result of several years experience and depends on the use of 'Teflon' (polytetrafluorethylene) containers. This plastic possesses several very significant properties including an almost complete resistance to chemical attack by most reagents except molten alkali metals. It also possesses a marked freedom from warping or softening at temperatures up to 300° C. This material is expensive (a 150-ml. beaker costs about £6) but will certainly outlast platinum and is only a fraction of the cost of this metal.

It is hoped that a description of the method will be of assistance to other workers, particularly in the geochemical sphere, and will help them to reduce the tedium of the dissolution stage of chemical analyses on silicate rocks.

The technique described step-wise below is based on a sample weight of 40 gm. and can be carried out in a 150-ml. 'Teflon' beaker. If greater or lesser quantities are required, *pro rata* volumes of reagents must be used. (*a*) Weigh 40 gm. of finely powdered sample (100 mesh or greater) into a 150-ml. 'Teflon' beaker. (*b*) Add 10 ml. of aqua regia and stir into a paste with a 'Teflon' rod. (*c*) Very cautiously add 50 ml. of 'AnalaR' hydrofluoric acid in small amounts of about 3 ml. each. This is a hazardous operation and care must be taken to avoid frothing. (*d*) Add a further 40 ml. of aqua regia and take to dryness in a water-bath. Because of the low heat transmittancy of 'Teflon', the beaker should be suspended actually inside the water-bath with the top of the beaker protruding about ¼ in. above the top of the bath. (*e*) When the sample is dry (usually about 24 hr.), add 50 ml. of hydrochloric acid and transfer contents to a 250-ml. borosilicate glass beaker. Add 150 ml. of water and boil for about 5 min., allow to settle for ½ hr. and pour off the supernatant solution. (*f*) Transfer the residue back to the 'Teflon' beaker and again add 50 ml. of hydrofluoric acid and 50 ml. of aqua regia. Caution in adding reagents is not necessary in this step. (*g*) Again take to dryness in the water-bath and combine the residue with the original decanted liquid. (*h*) Add 50 ml. of sulphuric acid to the solution and fume to dryness to remove excess fluoride ions. This step is carried out in a borosilicate glass beaker and slight etching of the glass may occur due to liberation of fluoride ions. This degree of etching is slight and may be ignored unless a determination of alkali metals is being carried out, in which case careful blanks are necessary. (*i*) Add about 200 ml. of 2 *N* hydrochloric acid to the residue and 1 ml. of bromine. Boil for 5 min. and add sufficient hydrochloric acid (2 *N*) to adjust the total volume to about 1,250 ml.

In most cases the above treatment will result in a clear solution. Some rock types, however, will not dissolve completely with this treatment and an appreciable sediment may result. In such cases the sediment should be separated from the supernatant liquid and fumed with 10–15 ml. of sulphuric acid; the residue should then be added to the decanted liquid and, after boiling, dissolution should be complete.

METALLURGY

Corrosion Inhibition and the Zero Charge Potential of Metals

THE electrode potential of a mild steel specimen immersed in sodium chloride solutions has been measured in conditions of very rapid aeration produced by bubbling air vigorously over the specimen. Corrosion is rapid, but the potential does not fall to the values observed in conditions of moderate aeration. It rises to a maximum value that can be maintained for an appreciable time even though corrosion continues at a rapid rate. (This maximum potential must be related to the maximum rate of cathodic depolarization as limited by the rate of diffusion of oxygen across the boundary layer on the surface of the metal.) The relationships between potential, chloride concentration and surface preparation of the steel are specific and reproducible and will be described elsewhere. At lower rates of aeration, lower (less-positive) steady potentials can similarly be maintained. This method of potential stabilization was used to test the theory put forward by De[1] for inhibition in neutral and acid solution. De suggested that inhibitive anions are adsorbed preferentially on metal/solution interfaces that are positive to the zero charge potential (potential of electrocapillary maximum) of the metal, that is, he suggested, on cathodic surfaces in neutral solution. Evidence for such preferential adsorption has been found by Hoar and Holliday[2], by Antropov *et al.*[3] and others for inhibition in acid solutions; but so far as I am aware no direct evidence exists for its validity in neutral solutions.

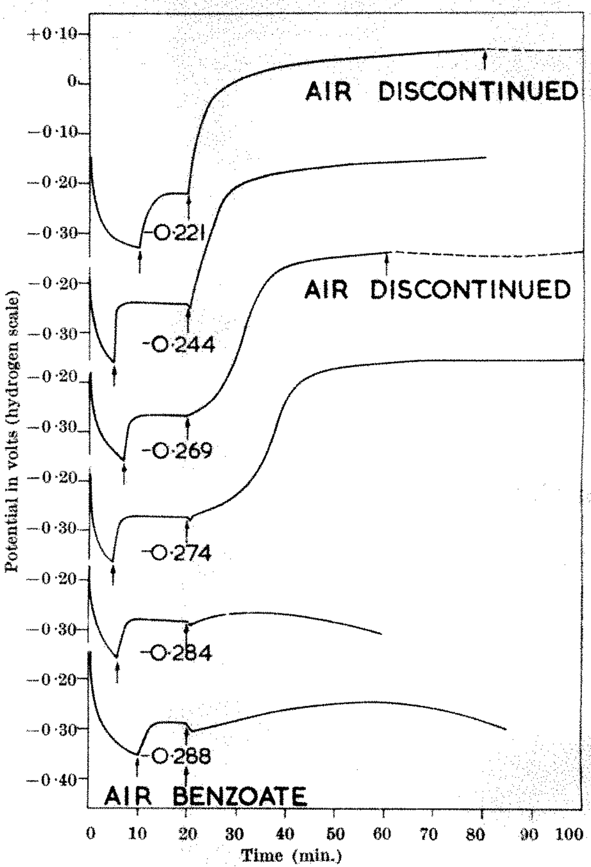

Fig. 1. Potential/time curves. Grit-blasted mild steel in 0·01 *M* sodium chloride

Grit-blasted specimens were suspended in 0·01 *M* sodium chloride (at approximately 20° C.), and after the potential had fallen to approximately −0·36 V. (hydrogen scale), which happens quickly in these conditions, a slow stream of air was passed through the solution (not over the specimen) at such a rate as to cause the specimen to attain a steady pre-determined potential. After 20-min. total immersion of the specimen, sodium benzoate was added, in sufficient amount to make the resulting concentration 0·1 *M*. From Fig. 1 it is seen that at potentials above −0·28 V. benzoate will induce inhibition; the higher the potential is above this value, the more readily does inhibition occur. Below this potential it will not induce inhibition. The conditions in all the solutions are precisely similar, the only variant being the potential reached by the specimen at the moment of addition of the benzoate. As the conductivity of the solution is high, the potentials of anodic and cathodic surfaces must be close together; hence adsorption presumably occurs over the whole surface irrespective of the anodic or cathodic nature of local areas.

If this hypothesis is correct, then the zero charge potential of steel in these solutions (0·01 *M* sodium chloride at *p*H 6) is approximately −0·28 V. (hydrogen scale). (Ayazyan[4] reports a value of −0·37 V. for iron in 0·001 *N* sulphuric acid.) Some corroboration that this value does correspond to the zero charge potential is provided by the growth of interference colour films on cathodically polarized surfaces; under similar conditions of *p*H, deposition of the positively charged colloidal corrosion product takes place at potentials just below this[5].

These results can now be used to interpret inhibitor mechanism in solutions that are in equilibrium with air, but not vigorously aerated. The primary function of oxygen (in all solutions of non-oxidizing inhibitors) is clearly to maintain the potential of the specimen above the zero charge potential for a sufficient time to enable the inhibitive anion to become adsorbed. De[6] showed that this took a measurable time (of the order of seconds) in the case of chromate ions. Upon immersion of the specimen, the potential will have a tendency to fall rapidly, the more so the higher the chloride concentration of the solution and the more reactive the metal surface (for example, grit-blasted in comparison with emeried); if the anion can become adsorbed quickly enough the fall in potential will be arrested and inhibition will ensue. For example, it was found that grit-blasted steel, in a stagnant solution of the same final composition as that of the solutions already used (0·01 *M* sodium chloride + 0·1 *M* sodium benzoate), remained protected, but only just; the potential fell slightly during the first 5 min. of immersion, then recovered. The 'fate' of the specimen will thus be decided by the relative speeds of two changes: the fall in potential (resulting from oxygen consumption and a decrease in anodic polarization) and the adsorption of anions. Aeration is not necessary in solutions of nitrite or chromate (or other oxidizing inhibitors), because these substances can raise the potential of the steel sufficiently to allow their own anions to become adsorbed.

This hypothesis explains several facts (hitherto unexplained) relating to inhibition by sodium benzoate. (*a*) Benzoate alone will not protect a badly rusted surface in stagnant conditions; in practice, the situation might be saved by a vigorous aeration 'boost'. (*b*) If benzoate is present in insufficient concentration to give inhibition, then general, but not localized, corrosion occurs. This may be ascribed to the utilization of the nearby oxygen in the early stages of breakdown, followed by a fall in potential, with consequent desorption of the rest of the benzoate anions. In highly aerated conditions, such as those produced by rapid movement, benzoate might no longer be a 'safe' inhibitor. With chromate or nitrite, even in stagnant solutions, the potential (except in case of excess chloride) tends to remain above the zero point owing to the oxidizing properties of these solutions. (*c*) The behaviour of steel in benzoate solution, when coupled to zinc or noble metals, was studied by Gilbert[7], who showed that (1) if steel and zinc were immersed separately in benzoate for 43 hr. and then connected, the potential of the couple was −0·21 V. (hydrogen scale), and the steel remained bright; (2) if steel and zinc in benzoate were connected from the outset, the steady potential of the couple remained in the region of −0·45 to −0·37 V.; that of galvanized steel remained at −0·35 V.; rusting of the steel took place in both cases; (3) no rusting occurred when steel was connected in benzoate solution to platinum, copper, or platinum with an externally applied current of 35 μamp., with the steel (1·5 cm. × 1·4 cm.) as anode; heavy rusting occurred if the current was reversed and the steel made the cathode. The potentials were not given but the results agree qualitatively with the hypothesis.

The potential of an immersed metal, relative to its zero charge potential, is clearly of fundamental importance in determining whether inhibition, due to adsorption of ions, is possible; in particular, a potential positive to the zero point is essential for inhibition by anions. Factors that determine this potential include the surface condition of the metal, the concentration of aggressive ions in the environment and the presence of oxygen or other cathodic depolarizers, contact with other metals or the passage of current.

Variation of Magnetic Moment with Composition in the Iron–Vanadium Sigma Phase

SINCE the structure of the sigma phase was established by Bergman and Shoemaker[1], it has been found in many binary alloys of transition elements (see, for example, Haworth and Hume-Rothery[2]). Where the phase boundaries have been established, the width of the range of composition varies from less than 1 per cent in the molybdenum–cobalt system to about 20 per cent in the iron–vanadium system. On the basis of the positions of the phase in various binary alloy phase diagrams, it has been suggested that the sigma phase is some kind of electron compound (see, for example, Kasper[3]). Greenfield and Beck[4] concluded that while the sigma phase might be associated with a particular average number of vacancies in electronic '*d*' states per atom, no self-consistent scheme could be developed to reconcile both theory and experiment. Nevertheless, the possibility that '*d*' state vacancies might play a part in stabilizing the structure suggests that magnetic evidence would prove of value. Consequently, in a survey of many binary and ternary sigma phase alloys, Nevitt and Beck[5] concluded that all were ferromagnetic, having Curie points in the temperature range 50–200° K. No measurements had been made,

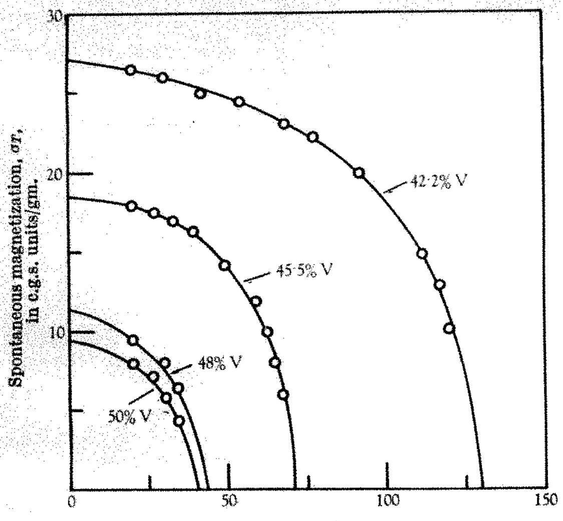

Fig. 1. Variation of spontaneous magnetization, σ_T, with temperature for the four iron–vanadium sigma phase alloys

however, of the mean magnetic moment per atom (p_B) of any ferromagnetic sigma phase, or of its variation, if any, with composition, and so the present work was undertaken, the iron–vanadium system being chosen because of the comparatively wide range of composition over which the sigma phase extends.

The alloys were prepared by melting together appropriate amounts of iron and vanadium in an electric arc furnace under an atmosphere of argon at a pressure of about 40 cm. of mercury. The iron used was B.I.S.R.A. iron of 99·96 per cent purity, and the vanadium was supplied by New Metals and Chemicals, Ltd., and was of 99·5 per cent purity. The sigma phase was precipitated by heating for four days *in vacuo* at 1,050° C., the presence of the phase then being confirmed by X-ray diffraction. Measurements of the magnetization were then made at temperatures between 20° K. and the Curie point and in applied magnetic fields of between 4 and 16 kilo-oersteds, using a Sucksmith ring balance[6]. The linear part of the magnetization curves at the constant temperature, T, were extrapolated to zero field to determine the spontaneous magnetization at that temperature, σ_T. The spontaneous magnetization at absolute zero, σ_0, and the Curie point, θ_f, were deduced using methods which have become standard in this laboratory (see Crangle[7]). The results are shown in Fig. 1 and Table 1, and from them it can be seen that there is a decrease in magnetic moment and Curie point with increasing vanadium content. A linear extrapolation of the curve of magnetic moment against composition goes to zero moment at a composition corresponding to about 53 per cent vanadium although the composition limit of the sigma phase is about 57 per cent vanadium. The Curie points are considerably lower than that of the α-phase of the same composition as deduced from Fallot[8], so ruling out the possibility that the ferromagnetism is due to retained alpha phase.

Table 1

Composition percentage V (by atoms)	σ_0 (c.g.s. units/gm.)	Curie point (° K.)	p_B (Bohr magnetons)
42·2 ± 0·5	27·1	130	0·261
45·5 ± 0·1	18·4	72	0·177
48·0	11·5	44	0·110
50 ± 2	9·5	40	0·091

There would seem to be two possible interpretations of the results.

If the magnetic moment of the sigma phase is due to a net unbalance of positive and negative spins in a common '*d*' band, then there is a redistribution of spins in the band as the composition changes, leading to a balance of spins at 53 per cent vanadium. The phase does not, however, cease to be stable at this point.

The alternative interpretation is that there is a ferri-magnetic arrangement of magnetic ions in the structure which alters with composition. This would seem to be the more probable interpretation, particularly in view of the fact that the curves of inverse susceptibility against temperature above the Curie point are slightly concave to the temperature axis.

The compositions quoted in Table 1 are based on the amount of each constituent present before melting, and the errors estimated from the loss in weight during melting.

Further work is in progress on the iron–vanadium system, and also on other sigma phase alloys.

It is a pleasure to record my thanks to Prof. W. Sucksmith for his advice and for his continued interest in the work.

The alloy quoted as containing 48 per cent vanadium was kindly supplied by Dr. B. R. Coles.

CHEMISTRY

Conductivity of Aqueous Sodium Stannate Solution

IN view of the attention which has recently been paid to the chemistry of silicates and germanates[1,2] the following results obtained during an investigation of the properties of sodium stannate solutions are of interest.

When sodium stannate, prepared by Zocher's method[3], is dissolved in water at 25·0° C. there is an immediate increase in *p*H, after which the solution becomes slowly more alkaline, reaching a steady limiting value after about one week. In order to follow this reaction the variation in conductivity with time was measured using an electrodeless capacity-coupled cell[4]. Over the whole of the concentration-range studied the specific conductance increased regularly with time and reached a limiting value after seven days. The specific and equivalent conductances at zero time were obtained by graphical extrapolation of the conductivity-time plots; the results are given in Table 1.

Table 1. Equivalent Conductance of Sodium Stannate Solutions at Zero Time

Molar concentration sodium stannate	0	$1\cdot035 \times 10^{-4}$	$1\cdot179 \times 10^{-4}$	$1\cdot735 \times 10^{-4}$	$2\cdot639 \times 10^{-4}$
Equivalent conductance (ohm^{-1} cm.^{2})	111·8	110·7	109·0	107·0	106·4
Molar concentration sodium stannate	$5\cdot485 \times 10^{-4}$	$7\cdot018 \times 10^{-4}$	$1\cdot051 \times 10^{-3}$	$1\cdot527 \times 10^{-3}$	$3\cdot553 \times 10^{-3}$
Equivalent conductance (ohm^{-1} cm.^{2})	105·0	103·1	100·3	99·5	93·9
Molar concentration sodium stannate	$4\cdot896 \times 10^{-3}$	$5\cdot216 \times 10^{-3}$	$6\cdot993 \times 10^{-3}$	$7\cdot564 \times 10^{-3}$	$1\cdot246 \times 10^{-2}$
Equivalent conductance (ohm^{-1} cm.^{2})	92·7	91·4	91·1	88·6	85·6

The equivalent conductivity at infinite dilution, 111·8, was obtained from a Kohlrausch plot; on correction for the effect of hydrolysis has been made. The difference between this value and the value of 156 obtained by Bellucci and Parravano[5] for potassium stannate is greater than the theoretical one. Bellucci and Parravano, however, only noted an increase in conductivity with time in their most concentrated solution, so it is possible that their potassium stannate was impure.

The increase in conductivity with time and the final attainment of a limiting value shows that the species initially present are reacting at a measurable rate. By means of *p*H measurements it has been shown that for approximately the first 70 per cent of the reaction the increase in specific conductivity is a direct measure of the increase in hydroxyl ion concentration of the solution. The rate of production of hydroxyl ions is a first or pseudo-first order reaction with a rate constant of $5\cdot3 \times 10^{-2}$ hr.$^{-1}$. The hydrolysis of sodium stannate is thus seen to occur in at least two stages: first, a fast reaction, typified by the immediate alkaline reaction of a freshly prepared stannate solution, and, secondly, by a slow first or pseudo-first order formation of more hydroxyl ions. Unfortunately, there are insufficient data available at present to make a more detailed mechanistic analysis of these reactions; but in view of the fact that both silicates and germanates form polynuclear hydrolysis products it seems likely that a similar explanation would apply in the case of stannate solutions.

I wish to thank the Superintendent of the Admiralty Materials Laboratory for permission to publish this work.

Toxicity of Plastics

In view of the ever-increasing use of plastics in contact with foodstuffs and like materials and the enormous amount of work done to establish their suitability for such uses, second thoughts on materials condemned without actual test might be advisable. In this respect I would like to direct attention to the results of a series of tests carried out in the laboratories of Bakelite, Limited.

We were asked to investigate the leaching-out of lead compounds from lead-stabilized polyvinyl chloride compositions in contact with a constant volume of hard and soft water. These tests were carried out by storing 6 litres of water at room temperature in tanks 18 in. × 12 in. × 5 in. deep made from the sample material by welding press-polished sheet and, after a period of 18 months contact with the water, determining the total lead content of the waters. It was shown that, with a compound stabilized with 3·77 per cent basic lead phosphite and lubricated with 0·94 per cent basic lead stearate, 0·5 part per million lead were extracted by soft water and no lead by hard water; while a compound, containing only 3·81 per cent dibasic lead phosphite, had none of its lead extracted by either hard or soft water. Thus it appears that only some types of lead compound are extracted from these compositions by water.

Although the test specimens employed and the test methods used are not those specified by the British Plastics Federation in its Toxicity Report No. 40, dated 1958, nevertheless, it is felt that the results are of considerable interest to the industry as a whole. If the total amount of lead extracted from a sample over a period of 18 months is only 0·5 part per million, then surely such a material would be satisfactory for use in pipes in contact with flowing water. In the event of water being stagnant in the pipes up to 18 months it could only produce a lead concentration of 0·5 part per million. On the other hand, formulations can be made which contain lead compounds, for example, lead phosphite, from which no lead is extracted either by hard or soft water. These results could, therefore, be considered good evidence in favour of allowing a formulation containing lead compounds to be employed in contact with water in conformity with Continental practice.

In conclusion, I suggest that polyvinyl chloride compositions should not necessarily be condemned as being toxic just because they contain toxic substances, but should be considered in the light of the applications for which they are intended to be used.

Separation Factors in Gas Chromatography

It is generally accepted among those using gas chromatography that for most separations the use of lower temperatures increases the separation factor, though, usually owing to the time taken at low temperatures, there is a limit to the use to which this effect can be put. Capillary columns can, however, be made extremely fast in their operation, and hence low temperatures can be used for separations which normally require temperatures at least 70° C. higher.

The classically difficult separation in gas chromatography is that of *meta*- and *para*-xylene. Although nowadays this separation is relatively commonplace owing to the use of capillary columns and selective stationary phases, an interesting separation was made in the course of routine testing at our laboratory which illustrates the effect of low-temperature operation. In this case, the stationary phase was a non-

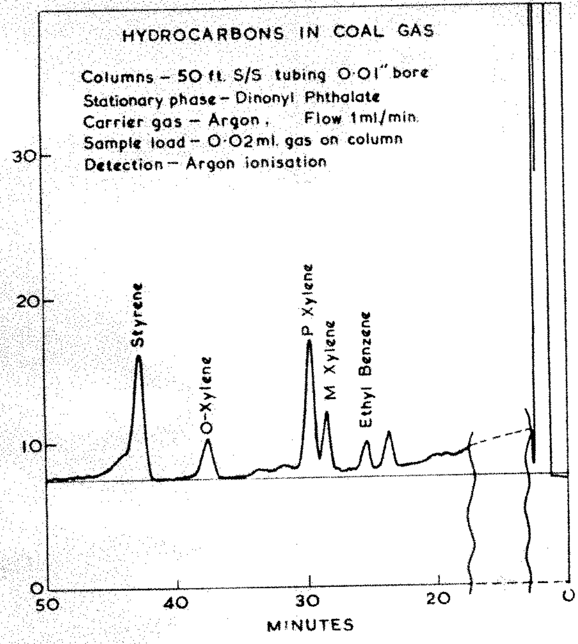

Fig. 1

selective one, dinonyl phthalate. At room temperature, these two isomers are easily separated, the separation factor being 1·05. A typical chromatogram is shown in Fig. 1. No separation is obtained at 80° C., although the plate number remains the same. It is clear that the principal separating factor with these two substances is their difference in vapour pressure, and that the difference is much greater at room temperature than it is at more elevated ones.

It is probable that the large increase in separation factor towards these really low temperatures is a general one.

BIOCHEMISTRY

Hepatotoxic Activity of Semi-Synthetic Analogues of Pyrrolizidine Alkaloids

MANY of the natural pyrrolizidine alkaloids isolated from various plants are not only acutely hepatotoxic, but are also able to produce subacute and chronic liver lesions in rats when given in an appropriate single dose. The most striking feature of the lesions are the cytological abnormalities of the liver parenchymal cells, suggesting that the alkaloids may be interphase mitotic poisons[1]. The hepatotoxic activity of these alkaloids, especially in relation to their basic moieties, has been discussed[2]. Though their structures vary greatly, yet one feature is common to all, namely, the branching of the carbon-chain of their acidic moieties, the necic acids.

Such structures could in the course of the metabolic degradation in the animal body yield isoprenoid units, or their homologues. In view of the finding that isoprenoid units, derived from mevalonic acid (3 : 5-dihydroxy-3-methyl-valeric acid), are incorporated *in toto* into squalene, the precursor of cholesterol[3], and probably into steroidal hormones, and other polyprenoids, it is conceivable that the hepatotoxic pyrrolizidine alkaloids interfere in some way with the biosynthesis of some such vital cell constituents. The fact that young, immature animals are more susceptible than adults, and males more than females, to the action of pyrrolizidine alkaloids[4] suggests also that steroidal hormones may be implicated.

Table 1. HEPATOTOXIC ACTIVITY IN RATS

Compound	Dose range (mgm./kgm. body-weight)	Cytological abnormalities of liver
Retronecine hydrochloric acid	600–1,000	–
Monocrotalic acid lactone (sodium salt)	400–1,300	–
Tiglic acid (sodium salt)	60–1,670	–
Tiglic amide	140– 600	–
Senecioic acid (sodium salt)	400–2,500	–
Senecioic amide	170– 500	–
Di-*n*-butyryl retronecine	175–1,300	–
Di-*n*-valeryl-retronecine	480– 730	–
Di-*iso*-valeryl-retronecine	300– 830	+ +
Di-tigloyl-retronecine	100– 500	+ +
Di-senecioyl-retronecine	200– 525	+ + +

Yet, the free necic acids obtained by hydrolysis of the natural alkaloids are not hepatotoxic, nor are synthetic acids with an isoprenoid structure such as senecioic or tiglic acids, or their amides (Table 1).

It was thought desirable to try to prepare semi-synthetic analogues of pyrrolizidine alkaloids with a series of related straight and branched-chain, monocarboxylic acids, in order to evaluate the significance of the branching of the carbon chain of the acidic moieties in relation to their hepatotoxic activity.

The amino-alcohol used for this purpose was natural retronecine, obtained by hydrolysis of monocrotaline (the main alkaloid of *Crotalaria retusa* L.), according to the procedure of Adams and Rogers[5]. This was esterified by the action of the respective acid chlorides, yielding mainly diesters. These were oily liquids, and were purified via their crystalline picrates. The preparation of di-senecioyl-retronecine may serve as an example. Retronecine hydrochloride was heated with an excess of redistilled senecioyl chloride, on a water-bath for 15 min.; the excess of the chloride was decomposed with alkali and the ester, extracted with ether, was isolated as a crystalline picrate, yellow needles, m.p. 115° C., from ethanol (found : C, 52·9 ; H, 5·24 ; N, 10·3 per cent : $C_{24}H_{28}N_4O_{11}$ requires C, 52·6 ; H, 5·1 ; N, 10·2 per cent). The diester, a colourless viscous oil, was recovered from the picrate by shaking with aqueous ammonia and extracting with ether. It formed a crystalline hydrochloride, colourless needles from acetone-ether, m.p. 126° C. (found : C, 60·5 ; H, 7·37 ; N, 4·3 per cent : $C_{18}H_{26}NO_4Cl$ requires C, 60·7 ; H, 7·3 ; N, 3·9 per cent).

For biological testing the respective compounds were dissolved, by the addition of equimolecular amounts of dilute hydrochloric acid, or in water when present as hydrochlorides, and various, single doses were given by stomach tube or by intraperitoneal injections to weanling Wistar rats. The animals which did not die within a few days were allowed to survive for at least 1–2 months, before they were killed and examined. The livers, lungs and sometimes other organs were then fixed and processed in the usual way for microscopic examination. The presence of significant numbers of characteristic large parenchymal liver cells was taken as evidence of hepatotoxic activity.

The diesters, when tested by intraperitoneal injections, caused convulsions and death of the rats, with

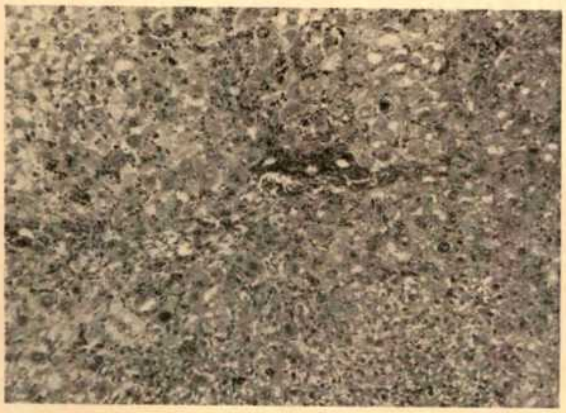

Fig. 1. Liver of a male rat, killed 3 months after a single dose of di-senecioyl-retronecine, 450 mgm./kgm. body-weight, showing great variation in the size of parenchymal cells and infiltration of portal areas (hæmatoxylin and eosin, × 100)

accompanying lung œdema, after doses much smaller than (about 1/5) those which produced similar effects by the oral route. Indeed, only some of the compounds were given in high enough oral doses to induce convulsions, which were then less intense and transitory, so that the animals only died a few days after the treatment.

Subacute liver lesions and cytological abnormalities indistinguishable from those seen after the natural pyrrolizidine alkaloids were produced by the diesters of retronecine with tiglic and senecioic acids, administered orally (Fig. 1). The doses required to produce these lesions were of the order 250–500 mgm./kgm. body-weight (Table 1). These doses are higher than those of the natural alkaloids, whether the cyclic or the open esters[2], which produce similar lesions. This may be due to the use of the synthetic products as such, without trying to resolve them into optically active isomers.

The liver lesions produced by di-*iso*-valeryl-retronecine were comparable, but no evidence of abnormalities were seen in the livers of rats given di-*n*-butyryl-, and di-*n*-valeryl-retronecine, even after doses as high as 1,300 mgm. and 730 mgm./kgm. body-weight, respectively.

These results are consistent with the view that branching of the carbon-chain of the acidic moieties is necessary for hepatotoxic activity of this class of compounds. With the possibility now open for the synthesis of appropriately labelled hepatotoxic analogues of pyrrolizidine alkaloids, further work on the mechanism of their toxic action can be pursued.

The experimental details of this work will be published elsewhere. We wish to thank Dr. C. D. Adams, Department of Botany, Achimota, and Dr. R. A. Galley, Tropical Products Institute, London, for their kind help in obtaining large quantities of *Crotalaria retusa* from Ghana, as a source of monocrotaline, and Dr. J. M. Barnes for his stimulating interest.

Formation of L-Xylosone from Ascorbic Acid

DURING a study of the carbonyl compounds produced during cider fermentations an immediate precipitate (*A*) was obtained at room temperature on addition of dinitrophenylhydrazine to a sulphited cider (that is, a cider obtained from a juice to which 150 parts per million sulphur dioxide had been added after milling and pressing the fruit). A similar precipitate was formed in a sulphited Bramley Seedling juice which had failed to ferment, but no appreciable precipitate was noted in non-sulphited fermentations. The derivative (*A*) on a paper chromatogram gave a blue colour with sodium hydroxide solution which indicated the possibility of osazone formation. Owing to the difficulty of purifying the 2 : 4-dinitrophenylhydrazine derivative, the phenylhydrazine derivative (*B*) was prepared from a sulphited cider at room temperature.

Paper chromatography, that is, examination of derivative *B* by running on the same untreated No. 1 Whatman paper and on borate-treated paper with the phenylosazones of glucose, xylose and arabinose in dioxane–heptane–water (2 : 1 : 1), suggested that *B* was xylosazone.

Table 1

	R (arabinosazone) values	
	Untreated paper	Borate-treated paper
L-Arabinosazone	1·00	1·00
D-Xylosazone	1·00	0·25
Isolated derivative (*B*)	1·00	0·25
D-Glucosazone	0·37	0·00

Derivative *B* was purified by elution from an alumina column[1] with alcohol–water (9 : 1) after washing with benzene, benzene–ether (1 : 1) and ether. After evaporating to dryness *B* was recrystallized from methanol–water and had a melting point 164–165°, identical with that of D-xylosazone. A mixed m.p. of *B* and D-xylosazone gave m.p. 196°, which indicated that compound *B* was L-xylosazone. The m.p. of L-xylosazone made from a commercial sample of L-xylose was 168–169° and a mixed m.p. of this derivative with compound *B* gave 166–167°. Compound *B* was, therefore, identified as L-xylosazone and the substance present in the cider as L-xylosone.

The origin of this substance is of some interest. Recent work has shown that sugars may be oxidized to osones by the action of bisulphite[2]. However, the xylose present in the cider-apple juices is D-xylose (shown by m.p. and mixed m.p. of isolated xylosazone and of an authentic specimen). A more likely source of L-xylosone is L-ascorbic acid, which has been shown to occur in appreciable amounts in cider apple juices[3]. During the milling and pressing processes prior to the addition of sulphur dioxide it would be expected that much L-ascorbic acid would be converted to L-dehydroascorbic acid, also dehydroascorbic acid may be present in amounts similar to ascorbic acid in apples[4]. Opening up of the lactone ring followed by decarboxylation would yield L-xylosone.

A sample of ascorbic acid was oxidized to dehydroascorbic acid with iodine solution and just decolorized with sulphur dioxide solution. Sufficient sulphur dioxide solution was then added to combine with the carbonyl groups. After standing three days at room temperature the solution on addition of 2 : 4-dinitrophenylhydrazine rapidly gave a precipitate in the cold. A larger precipitate was obtained after boiling the solution for 30 min. Addition of phenylhydrazine and acetic acid gave an osazone in the cold with m.p. 164–165° unchanged on mixing with L-xylosazone isolated from cider. Standing or heating L-dehydroascorbic acid with sulphur dioxide therefore formed L-xylosone.

Previous work has shown that ascorbic acid is oxidized by perinaphthindan-2 : 3 : 4 trione hydrate at 45° to dehydroascorbic acid, which then undergoes hydrolysis and decarboxylation to yield L-xylosone[5]. Similarly, oxidation with ninhydrin[6] and alloxan[7] was followed by decarboxylation with the probable formation of L-xylosone. The formation of L-xylosone from dehydroascorbic acid in the presence of sulphur dioxide is of interest in view of the high proportion of dehydroascorbic to ascorbic acid in apples, pears and cherries[4] and of the use of sulphur dioxide as a preservative in other food products.

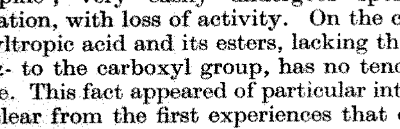
Anticholinergic Activity of Tropine-α-Methyltropate

THE synthesis of the new α-methyltropic ester of tropine and the isolation of the two optically active isomers has been recently described by Melone, Vecchi, Pagani and Testa[1].

These compounds (DL, (+)- and (−)-tropine-α-methyltropate) were supposed to display an anticholinergic activity possibly different from atropine itself (especially as far as the duration of action is concerned). In fact, the above-quoted authors, as well as Foster and Ing (who attempted to synthesize the same compounds[2]), had suggested that the esters of α-methyltropic acid, being very difficult to hydrolyse, should lead to quite stable compounds. Moreover, the natural occurring (−)-atropine, practically responsible for most of the action of atropine[3], very easily undergoes spontaneous racemization, with loss of activity. On the contrary, α-methyltropic acid and its esters, lacking the hydrogen in α- to the carboxyl group, has no tendency to racemize. This fact appeared of particular interest, as it was clear from the first experiences that only the (−)-isomer of tropine α-methyltropate possesses a significant anticholinergic activity.



Tropine-α-methyltropate

The stability of tropine α-methyltropate was believed to exercise an influence not only on the degree but also upon the duration of the pharmacological effects, as it is well known that the natural alkaloid, atropine, is destroyed by mammalian tissues, mostly through enzymatic hydrolysis of the ester to tropine (or tropanol) and tropic acid[4].

This communication concerns the results of a preliminary pharmacological investigation, carried out on (−)- and (+)-tropine α-methyltropate hydrochlorides.

The anticholinergic activity of the two compounds was evaluated and compared with that of atropine sulphate, on isolated rat gut and on the cardiovascular response of the dog to intravenously injected acetylcholine.

Acute intravenous toxicity was studied in *CF*-1 mice.

In isolated rat intestine the products were added to the oxygenated Tyrode solution of the bath chamber in fixed volume of 0·2 ml., 1 min. before the introduction of acetylcholine chloride. The recorded effects were evaluated as reduction of the contractile response to acetylcholine.

In preliminary tests it was demonstrated that (−)- and (+)-isomers and atropine display an anticholinergic activity qualitatively similar.

The concentration/activity curves of the three drugs were found to be parallel, thus allowing the estimation of relative potency. Three comparisons were carried out: between atropine sulphate and the (−)-α-methyl derivative hydrochloride; between atropine sulphate and the (+)-α-methyl derivative hydrochloride; and finally between the two optical antipodes. By calculating the ratios between equally effective concentrations (that is, the concentrations effective in reducing to 50 per cent the response of acetylcholine afterwards administered) the following potency ratio resulted:

Atropine/(−)-methylatropine (No. of experiments, 8)	1–2
Atropine/(+)-methylatropine (No. of experiments, 7)	1–0·04
(−)-Methylatropine/(+)-methylatropine (No. of experiments, 9)	1–0·02

The average effective concentration of atropine sulphate was found to be within a range of 0·016–0·012 μgm./ml. The average effective concentration of (+)-α-methylatropine was found to be 0·36–0·22 μgm./ml., while for (−)-α-methylatropine it was found to be 0·0074–0·0038 μgm./ml.

In dogs anæsthetized with sodium pentobarbitone the ability of (−)-methylatropine and atropine sulphate to prevent the fall in blood pressure caused by intravenous administration of 2 μgm. of acetylcholine was compared and the duration of the inhibitory effect especially considered. Each of the two products was injected intravenously in doses of 5 μgm./kgm. and acetylcholine administered before and 2, 6, 16, 26, 36 and 46 min. after the dosage until the fall in blood pressure produced by acetylcholine was returned to pre-treatment level. Six dogs were employed for these experiments. Three of them received the two products alternately. The three other dogs received the two drugs on the basis of a random schedule. The dose-level of 5 μgm./kgm. was chosen after preliminary assays that demonstrated this to be approximately the average effective dose for the two drugs.

In Table 1 the results of these experiments are briefly summarized.

The *LD*50 of (−)-atropine-α-methyltropate after intravenous administration in mice was found to be 102 mgm./kgm. (confidence limits $P = 0{\cdot}05$: 89·57–116·3) (according to Litchfield and Wilcoxon[5]), while for atropine the intravenous *LD*50 is 76·7 mgm./kgm. (confidence limits: 71·8–81·9). Also acute toxicity of both drugs in mice after intravenous administration gave the same result.

Table 1

Compound	No. of experiments	Dose (μgm./kgm.)	Average inhibition (per cent) of the depressor effect of acetylcholine (2·0 μgm./kgm.) after					
			2 min.	6 min.	16 min.	26 min.	36 min.	46 min.
Atropine sulphate	18	5	81·00 ± 7·62	59·50 ± 6·13	41·16 ± 7·32	27·83 ± 8·48	13·20 ± 7·33	3·80 ± 1·64
(−)-Methylatropine	15	5	81·20 ± 5·58	51·60 ± 10·4	34·00 ± 7·72	23·25 ± 9·24	13·00 ± 8·19	10·75 ± 8·29

Our preliminary experiments indicate that between the two optical antipodes of the new derivative tropine-α-methyltropate, the (−)-isomer shows *in vitro* a cholinergic blocking activity about fifty times greater than the corresponding (+)-isomer. This difference is substantially of the same order as between the optical isomers of the naturally occurring alkaloid atropine. Bovet and Bovet-Nitti[3] report that *l*-hyosciamine is ten to one hundred times more active than the *d*-isomer, according to different evaluations.

In *in vitro* experiments (−)-atropine-α-methyltropate hydrochloride shows an anticholinergic activity twice as great as atropine sulphate. In the dog, however, atropine sulphate and (−)-tropine-α-methyltropate hydrochloride were found equivalent in their ability to prevent the depressor effect of acetylcholine on blood pressure. Although there is no experimental evidence to support the hypothesis that the great resistance of (−)-atropine-α-methyltropate to hydrolysing agents could implicate a greater duration of pharmacological activity, the preliminary results herein reported seem to indicate that (−)-tropine-α-methyltropate is a drug of potentially practical value.

11α-Hydroxylation of Steroids by *Streptomyces* Species

Extensive studies[1] in the past few years have shown that the ability to transform the steroid molecule is widespread among various micro-organisms, and the types of reaction are numerous. Among them, 11α-hydroxylation is a quite common reaction with fungi[1,2]. More recently, it was found that two strains of bacteria have introduced the hydroxy group in progesterone[3] and Reichstein's[4] compound *S* at the 11α-position. However, with Actinomycetes this 11α-hydroxylation has not been reported, while 11β-hydroxylation of compound *S* by *Streptomyces radiae*[5] has been shown.

In the present communication we wish to report that microbiological hydroxylation of progesterone and Reichstein's compound *S* in the 11α-position and the 6β-position has been carried out by unidentified *Streptomyces* species (*Ac*-103) isolated from soil. In our experiment, *Streptomyces* sp. (*Ac*-103) was incubated in a medium containing 1 per cent glucose, 1 per cent peptone, 1 per cent meat extract and 0·3 per cent sodium chloride. After incubation at 28° for a period of 48 hr. on a reciprocating shaker, 1 gm. of the steroid substrate dissolved in methanol was added to 2 l. of medium and the incubation was continued for 48 hr. The culture filtrate was extracted with ethyl acetate ester and the extracts were concentrated to dryness *in vacuo* at 30°. The residue was redissolved in benzene or ethylene dichloride and the solution was chromatographed on an alumina or 'Florisil'.

When progesterone was used as a substrate in the incubation with this micro-organism, 6β,11α-dihydroxyprogesterone was isolated as the insoluble matter in benzene of the condensed residue of extract. Crystallization of this insoluble matter from acetone afforded 400 mgm. of 6β,11α-dihydroxyprogesterone (I), m.p. 234–240°, $[\alpha]_D + 110°$ (methanol), $\lambda_{\mathrm{max.}}^{\mathrm{MeOH}}$ 236 mμ ($\varepsilon = 14,200$), $\lambda_{\mathrm{max.}}^{\mathrm{KBr}}$ 3,420 (OH), 1,695 (20-CO), 1,660 and 1,615 (Δ^4-3-CO) cm.$^{-1}$. The diacetate of (I) prepared with acetic anhydride and pyridine melts at 150–153°, $[\alpha]_D + 70°$ (chloroform). The infra-red spectra of these compounds agreed with those of authentic samples. Then, the benzene solution filtrate was chromatographed on alumina and benzene–ether–chloroform gradient elutions were used for the separation of other oxygenated steroids. In the first fractions a small amount of progesterone was obtained, and in the second fractions 6β-hydroxyprogesterone was obtained. The crystallization of the second fractions from acetone gave 100 mgm. of 6β-hydroxyprogesterone (II), m.p. 172–173°, $[\alpha]_D + 98°$ (chloroform), $\lambda_{\mathrm{max.}}^{\mathrm{MeOH}}$ 236 mμ ($\varepsilon = 13,700$), $\lambda_{\mathrm{max.}}^{\mathrm{KBr}}$ 3,450 (OH), 1,710 (20-CO), 1,669 and 1,620 (Δ^4-3-CO) cm.$^{-1}$.

When Reichstein's compound *S* was used as a steroid substrate, the 6β-hydroxylated product and 11α-hydroxylated product were obtained by column chromatography on 'Florisil' using ethylene dichloride–acetone gradient elutions. The product obtained by recrystallization of the first fractions from acetone was 320 mgm. of 6β,17α,21-trihydroxy-4-pregnene-3,20-dione (III), m.p. 230–235°, $[\alpha]_D + 51°$ (methanol), $\lambda_{\mathrm{max.}}^{\mathrm{MeOH}}$, 238 mμ ($\varepsilon = 13,300$), $\lambda_{\mathrm{max.}}^{\mathrm{KBr}}$ 3,420 (OH), 1,710 (20-CO), 1,665 and 1,615 (Δ^4-3-CO) cm.$^{-1}$. The 6,21-diacetate melts at 190–195°, $[\alpha]_D +$ 60° (methanol). Crystallization of the second fractions afforded 120 mgm. of 11α,17α,21-trihydroxy 4-pregnene-3,20-dione (IV), m.p. 205–210°, $[\alpha]_D +$ 117° (methanol), $\lambda_{\mathrm{max.}}^{\mathrm{MeOH}}$, 242 mμ ($\varepsilon = 14,400$), $\lambda_{\mathrm{max}}^{\mathrm{KBr}}$ 3,442 (OH), 1,715 (20-CO), 1,653 and 1,615 (Δ^4-3-CO) cm.$^{-1}$. The 11,21-diacetate melts at 206–208°, $[\alpha]_D + 120°$ (methanol). The infra-red spectra of these compounds agreed with those of authentic samples.

From this experiment, 11α-hydroxylation of a steroid, which is one of the most important and common reactions among fungi, is carried out equally by Actinomycetes, fungi and bacteria. But, it may be worth mentioning that there is a remarkable difference in bioconversion patterns between Actinomycetes and fungi, for although both *Streptomyces* sp. and fungi, for example *Rhizopus arrhizus*, produced the same 6β, 11α-dihydroxyprogesterone as a dihydroxylated product from progesterone, they produced a different monohydroxylated product; *Streptomyces* sp. produced 6β-hydroxyprogesterone and, in contrast, *Rhizopus arrhizus* 11α-hydroxyprogesterone. So the enzyme systems of these two micro-organisms would appear to be different.

We wish to express our thanks to Prof. K. Tsuda and Prof. T. Asai of the Institute of Applied Microbiology, University of Tokyo, for their helpful advice and constant guidance throughout this work.

Histochemical Demonstration of a Species-Specific Trypsin-like Enzyme in Mast Cells

DURING the investigation of a new histochemical substrate, N^α-benzoyl-*dl*-arginine-β-naphthylamide hydrochloride, localization by a simultaneous azo coupling reaction of enzymatic activity to mast cells in human and dog tissues was noted. Recently, Benditt has described the presence of an enzyme in the mast cells of numerous species resembling bovine α-chymotrypsin. This enzyme hydrolyses the histochemical substrate 3-chloroacetyl-2-naphthoic acid anilide[1]. Although N^α-benzoyl-*dl*-arginine-β-naphthylamide hydrochloride has been shown in biochemical systems to be a substrate for trypsin and not for α-chymotrypsin, carboxypeptidase, liver esterase or 'leucine' aminopeptidase[2], it was thought of importance to attempt to define as closely as possible the characteristics of the enzyme in mast cells hydrolysing N^α-benzoyl-*dl*-arginine-β-naphthylamide hydrochloride and to differentiate it from other known mast cell enzymes.

N^α-benzoyl-*dl*-arginine-β-naphthylamide hydrochloride was synthesized by the mixed anhydride method[3]. Coupling of N^α-benzoyl-N^ω-nitro-*l*-arginine with β-naphthylamine was effected in 60 per cent yield, the product melting at 220–3°. The nitro group was removed by hydrogenation with a palladium catalyst in dilute hydrochloric acid to afford optically inactive N_α-benzoyl-*dl*-arginine-β-naphthylamide hydrochloride, m.p. 195–7° (ref. 4). Racemization apparently occurred in the course of activating the benzoylated amino-acid. 3-Chloroacetyl-2-naphthoic acid anilide was synthesized by the method of Gomori[5].

The incubation medium used in the histochemical experiments consisted of 30 mgm. of N^α-benzoyl-*dl*-arginine-β-naphthylamide hydrochloride and 10 mgm. of stabile diazotized 5-methyl-4-(nitro-*p*-tolylazo)-*o*-anisidine[6] (diazotized *o*-aminoazotoluene[7] may also be used) dissolved in 20 ml. of $M/20$ *p*H 7·0 *tris* buffer. Fresh frozen sections of skin or sections fixed for 16 hr. in neutral 10 per cent formalin at 4° C. were incubated in the above solution for 20–30 min., placed in a 1 per cent copper sulphate solution for 10 min., washed in running water, and mounted in glycerin gelatin containing several drops of a 1 per cent copper sulphate solution. Dark purple granules of the azo dye were observed only in mast cells (Fig. 1). The possibility of non-specific azo dye or naphthylamine binding by mast cell granules was eliminated when it was observed that tissue sections exposed to either a neutral aqueous suspension of the free naphthylamine (later coupled with diazonium salt) or the final azo dye showed no selective staining of mast cells. Enzymatic activity was completely abolished by di*iso*propylfluorophosphate (10^{-4} M), copper sulphate (2×10^{-3} M) and lead nitrate (2×10^{-3} M), but potassium cyanide (5×10^{-4} M and 10^{-2} M), sodium iodoacetate (10^{-3} M) and soybean trypsin inhibitor (1 mgm./ml.) failed to affect enzyme activity significantly. When stable tetrazotized di*ortho*anisidine[8] was used as the diazonium component in the histochemical system, inhibition of enzymatic activity was complete. This diazonium salt did not inhibit hydrolysis of 3-chloroacetyl-2-naphthoic acid anilide by mast cells.

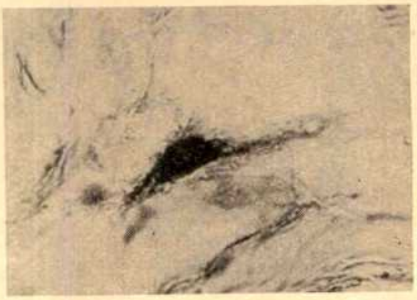

Fig. 1. Localization of trypsin-like enzyme in mast cell of human skin

Test-tube experiments with 0·5 ml./mgm. portions of salt-free crystalline α-chymotrypsin and trypsin (bovine) using N^α-benzoyl-*dl*-arginine-β-naphthylamide hydrochloride incorporated as substrate at a concentration of 5 mgm./ml. confirmed the failure of hydrolysis of N^α-benzoyl-*dl*-arginine-β-naphthylamide hydrochloride by chymotrypsin in 18 hr., and substantiated the rapid hydrolysis of the substrate by trypsin[2]. The method used for demonstration of hydrolysis in test-tube experiments was similar to that previously described[2] in which N^α-benzoyl-*dl*-arginine-β-naphthylamide hydrochloride alone was incubated in the presence of enzyme and buffer. The released naphthylamine was estimated, following removal during incubation of aliquot samples, by azo coupling and extraction of the azo dye product. In a separate experiment the same stabilized diazonium salts used in the original histochemical procedure[6,7] were incorporated (0·5 mgm./ml.) in the trypsin incubating medium. No hydrolysis by trypsin as determined by extraction of azo dye was noted. This indicated that inhibition of trypsin activity by the diazonium salt or its stabilizer had occurred, though this inhibition did not occur in the histochemical system. Preliminary experiments to demonstrate competitive inhibition by the method of Benditt and Arase[9] revealed inhibition by N^α-benzoyl-*l*-arginine amide hydrochloride, a substrate rapidly hydrolysed by trypsin but not by chymotrypsin. Tissues of rat, rabbit, guinea pig, mouse, dog and human were examined for evidence of hydrolysis of N^{α}-benzoyl-*dl*-arginine-β-naphthylamide hydrochloride by mast cells and only the latter two revealed enzymatic activity.

It is evident from the above results that the species-specific enzyme in mast cells demonstrated using N^{α}-benzoyl-*dl*-arginine-β-naphthylamide hydrochloride as substrate has properties that relate it to, but do not identify it with, trypsin. The mast cell enzyme requires no apparent activation, is irreversibly inhibited by di*iso*propylfluorophosphate and competitively inhibited by N^{α}-benzoyl-*l*-arginine amide hydrochloride, but is not inhibited by soybean trypsin inhibitor or specific diazonium salts[6,7]. It differs from the enzyme described by Benditt in its apparent absence from rodent mast cells and its inhibition by a specific diazonium salt[8]. The competitive inhibition of N^{α}-benzoyl-*dl*-arginine-β-naphthylamide hydrochloride by N^{α}-benzoyl-*l*-arginine amide hydrochloride is indicative, but not definitive evidence of its dissimilarity from the chymotrypsin-like enzyme. The fact that N^{α}-benzoyl-*dl*-arginine-β-naphthylamide hydrochloride is not a substrate for α-chymotrypsin further substantiates this distinction. Inhibition of the trypsin-like enzyme by di*iso*propylfluorophosphate and lack of inhibition by cyanide distinguishes it from the aminopeptidase-like enzyme described in mast cells[10].

The physiological function of this trypsin-like enzyme in mast cells of certain species is not known, but it may possibly act to liberate secretory granule substance. It has been shown that lysis of mast cell granules is, in fact, proteolysis[11] and that activation of a trypsin-like enzyme (present in an inactive state in guinea pig mast cells) produces in these cells a hydrolysis of protein and release of histamine[12]. It has further been demonstrated that heparin is bound to protein at the time of its release from mast cells and that its release is dependent upon proteolysis[13]. It is therefore conceivable that as the result of a variety of injurious stimuli, a trypsin-like enzyme is either activated (rodents) or released from *in situ* inhibition (humans and dogs) within the mast cell cytoplasm. The incident intracytoplasmic proteolytic action of this enzyme may then liberate secretory granule substance[14].

ANIMAL PHYSIOLOGY

Excretion of Rose Bengal in Bile

THE metabolism of rose bengal has been investigated by us in humans as well as in experimental conditions in animals. When we examined the dye by one-dimensional paper chromatography using 25 per cent ethanol and 5 per cent ammonia (1 : 1) as a solvent[1], we found it contained several components.

When a commercial preparation of rose bengal (Hopkins and Williams) was examined in ethanol–ammonia at least six components were distinguished in visible light, five red or orange-red (*R*1–*R*6) and one yellow (*Y*). The biggest spot was a red component (*R*3) with an R_F-value of about 0·50. Two other red components with R_F-values of 0·62 (*R*4) and 0·70 (*R*5) were second and third, respectively, in size. The other components appeared less prominent. In ultra-violet light all the above-mentioned components were seen fluorescing, the yellow spot having the brightest fluorescence. At least four faintly fluorescing spots (*F*1–*F*4), which could not be detected in visible light, were seen in ultra-violet light. In addition, radioactive preparations of rose bengal (Abbott) labelled with iodine-131 have been examined, and the distribution of radioactivity on the chromatogram estimated by scintillation counting and autoradiography. Some 51 per cent of the radioactivity was found localized to the spot *R*3. The *R*4 and *R*5 components contained 38 and 9 per cent respectively of the total radioactivity. We have found that there are great variations of the distribution of the radioactivity in the components *R*3–*R*5 of different batches of radioactive rose bengal, but the sum of radioactivity of *R*3–*R*5 usually amounts to more than 90 per cent of the total radioactivity. A slight blackening corresponding to the yellow spot was seen on the autoradiogram. Other details are seen in Fig. 1.

After intravenous injection into rats of the radioactive rose bengal together with a suitable amount of carrier, bile was collected and the excreted dye was extracted in ether after acidification of the bile. The ether-extracted rose bengal was subjected to paper chromatography in ethanol–ammonia. All components of the injected dye were recovered and

Chromatography of rose bengal in ethanol–ammonia. *S*, starting point ; *F*, solvent front. *R*1–*R*6, red components, and *Y*, yellow component, seen in visible light ; *F*1–*F*4, fluorescing components only seen in ultra-violet light of the stable dye. *ARG* 1, autoradiogram of a chromatogram of a radioactive stock solution of rose bengal. *ARG* 2, autoradiogram of a chromatogram of radioactive rose bengal recovered from bile. The diagram shows the distribution of radioactivity on the chromatogram

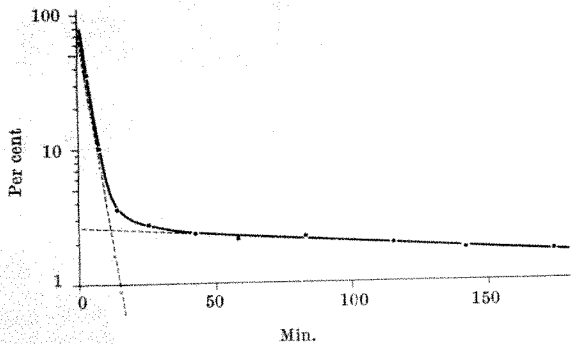

Fig. 2. Blood disappearance curve of radioactive rose bengal in the rat

in about the same proportions. Even the yellow component was excreted in the bile (Fig. 1).

The blood disappearance curve of rose bengal in the rat after injection of an iodine-131 labelled dye could be expressed as an approximate bi-exponential function. The disappearance rate of one phase was very slow; that of the other rather fast. When extrapolated to zero, the slow phase did not amount to more than 4 per cent of the dose injected (Fig. 2).

In accordance with Lima and Pieroni[2], we have found that rose bengal is not a pure compound but a mixture of several chemical substances. The explanation of the bi-exponential blood disappearance curve, however, can scarcely be based on this fact because the liver, as indicated above, is capable of removing all components of rose bengal from the blood. Furthermore, since the proportions between the components are roughly the same in the bile as in the injected material, no other organ seems to be responsible for a specific removal of any of the components. There is still a possibility that the liver might remove one of the small components of rose bengal from the blood at the slower rate. Thus we injected large amounts of radioactive rose bengal into rats. When the blood disappearance curve had reached its 'tail' portion the animals were killed and blood serum collected. When this radioactive serum was injected into rats the usual bi-exponential blood disappearance curve of rose bengal appeared.

The bi-exponential curve can be explained by assuming that there is a back-flow into the blood of a fraction of the amount of rose bengal in the liver cells. It then appears as if the percentage of the dye eliminated from blood will diminish in time and reach a low value.

We have observed that a back-flow to the blood of the rose bengal of the liver cells really can occur; for example, when rose bengal is injected 15 min. after bile obstruction the usual initial fall in the blood curve is followed by an increase in the blood radioactivity.

Inhibitory Actions of γ-Aminobutyrylcholine

Since the existence of γ-aminobutyrylcholine in the mammalian brain and the possibility of its being a neurotransmitter have been reported[1], new findings on this substance have been reported by several investigators. Takahashi *et al.*[2] noticed its inhibitory effect on the electrical activity of the brain. McLennan[3] found that the second active ingredient of his factor 1 can be accounted for by this compound biologically but not chromatographically; and Kewitz[4] claims to have isolated γ-aminobutyrylcholine in crystalline form from the brain of the pig. In view of its anticholinergic and antihistaminic activities[1], we thought it worth while to study further its inhibitory properties on some other preparations.

The isolated heart of a clam, *Meretrix lusoria* Röding[4], reacted to γ-aminobutyrylcholine with decrease of tonus and the amplitude of beats. This action could be observed at a concentration of 10^{-2} *M* but not at 10^{-3} *M*. Washing removed all the effect. Similar action was exhibited by another choline ester of amino-acid like glycylcholine which was even more potent than γ-aminobutyrylcholine in this respect, and was active at the concentration of 10^{-4} *M* but not at lower concentrations. Unlike γ-aminobutyrylcholine, γ-aminobutyric acid caused short lasting tonic contraction of the heart at 10^{-1} *M*, but it was inactive at 10^{-2} *M*.

In the crayfish intestine, inhibitory potency of γ-aminobutyric acid and of γ-aminobutyrylcholine was about the same, both being effective up to 10^{-4} *M* but not effective at 10^{-5} *M*.

On the neuromuscular preparation of the crayfish claw[5], γ-aminobutyric acid and γ-aminobutyrylcholine elicited qualitatively similar action, inhibiting contraction of the indirectly stimulated closer muscle. After injection of either one, the height of its contraction showed a continuous decrease, but their effect was removed by washing with pure crayfish solution. γ-Aminobutyric acid was more potent; at 10^{-1}–10^{-3} *M* it caused complete block of the contraction and at 10^{-4} *M* the inhibitory action was still distinctly noticeable. γ-Aminobutyrylcholine also caused complete loss of contractility at 10^{-3} *M*, but not at lower concentrations, though its inhibitory effect was still noted at 10^{-4} *M*. Butyrylcholine was less potent than γ-aminobutyrylcholine in this inhibitory action, and glycylcholine was much less active.

Thus, there are some differences in potency and quality of their inhibitory actions, depending upon preparations used for study.

The most pronounced effect was observed on the cat's sciatic-gastrocnemius preparation of Brown. Following intra-arterial injection of 0·02 μgm. of γ-aminobutyrylcholine, the muscular contraction by indirect stimulation decreased in height rapidly, then disappeared, but resumed later (Fig. 1). With higher dose (20·0 μgm.), increase of the tonus set in. With

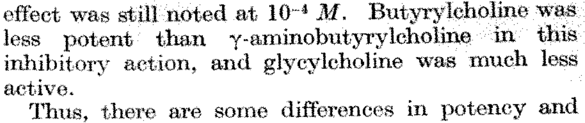

Fig. 1. Kymograph record of the contraction of cat's gastrocnemius muscle stimulated through the sciatic nerve with square wave stimulator. γ-Aminobutyrylcholine, 0·02 μgm. At the point indicated, it was injected intra-arterially in the dose of 0·02 μgm.

much higher dose (200·0 μgm.), the muscle reacted with irregular fibrillary twitches, instead of normal contraction, to the stimulation of the nerve, and after a while it became quite unresponsive. Such an extreme potency of γ-aminobutyrylcholine on the mammalian neuromuscular transmission is noteworthy. Besides, this property is dissimilar from that of the inhibitory factor of McLennan, which is reported not to affect this preparation[6]. Glycyl-, propionyl-, and butyryl-choline were also inactive at doses of 0·4, 4·0, and 40·0 μgm., except that 40·0 μgm. of propionylcholine caused temporary fall of the size of contraction.

Thus, γ-aminobutyrylcholine exerts a definite inhibition on various activities. A part of it may be due to its anticholinergic activity already reported[1]. However, since it has other properties such as antihistaminic action in addition, its inhibitory activity should not be ascribed solely to competition at the acetylcholine receptor. Further studies are necessary for understanding the mechanism of its inhibitory actions.

Fracture Healing by Vitamin K

THE aim of this short communication is to report on the pronounced effect of vitamin K in speeding up the rate of bone healing. Some clinical observations (Bouckaert, A., and Hart Kliniek, H., personal communication) and preliminary experiments (Bouckaert, J. H., and Oyaert, W., personal communication) indicated that vitamin K had a real effect on all collagen tissues and especially bone tissue.

Adult male and female rabbits and rats were used in this study. Complete transverse fractures of the left tibia were produced by an open operation under ether anæsthesia. In the case of rabbits intramedullary pins were used to fix the fractured ends of the bone. In rats the fractures were supported by maintaining the fibulæ intact. The operation wound, which was thereafter closed with catgut, healed uneventfully in nearly all cases. All animals were kept under the same dietary conditions on a well-balanced ration, fed and watered *ad libitum*. Various groups of animals received vitamin K while others served as controls.

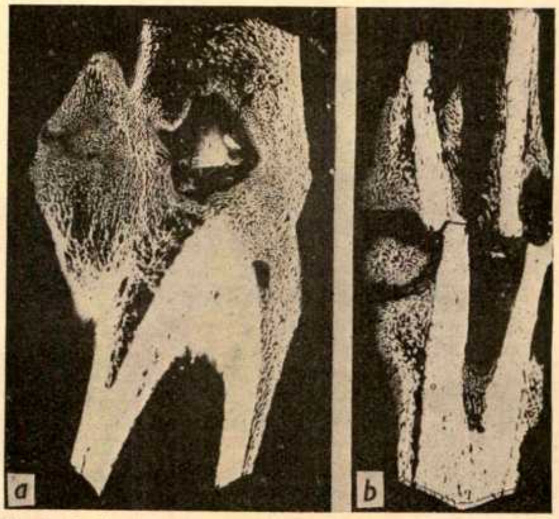

Fig. 1. Radiomicrographs from fractured tibiæ of *a*, an animal receiving vitamin K ; *b*, a control animal

Fig. 1*a* is a radiomicrograph of a fractured rabbit tibia after treatment with vitamin K. It shows a well-developed periosteal callus and the interfragmentary space woven with primary bone in a comparatively high degree of mineralization. Fig. 1*b* is a radiomicrograph of a control animal which received no medicaments. Here the periosteal callus is not complete. The space between the fractured ends is occupied with tissues devoid of any mineral deposition. Ordinary radiographs showed a complete continuity of the fractured bone of the treated animal in contrast to persistence of the fracture site in the control.

Full details about the further steps in our study with vitamin K singly or combined with other therapeutics as well as its exact mode of action will appear elsewhere.

Effect of Fœtal Hypophysectomy on the Fœtal Liver Fat in the Rabbit

ANGEVINE[1], in his study of the pituitary and adrenals of 20 human anencephalic fœtuses, noted that in practically every case the subcutaneous pannus of fat was unusually thick especially over the shoulders and thorax. This observation has been confirmed in a number of full-term or near full-term anencephalics which are now being studied. Jost[2] has recently shown that fœtal thyroidectomy in the rabbit results in an increase in total fat (determined by ether–alcohol extraction), which does not occur if thyroxine is injected into the fœtus at the time of the thyroidectomy. This raises the possibility that the increase in fat in the human abnormality is due to a fœtal hormonal disturbance, and this view is supported by the knowledge that the pituitary of anencephalics is reduced in size and that secondary to this the adrenals are extremely small[1]. It is therefore possible that the hypofunction of the pituitary either directly, or indirectly by affecting other endocrine glands, determines the increase in fat found in the human anencephalic monster.

To study this aspect of anencephaly further it was decided to investigate the effect of removing the

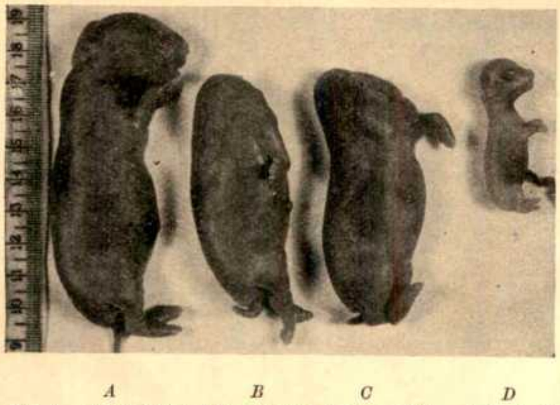

Fig. 1. Effect of fœtal decapitation in the rabbit. *A*, Control fœtus, 28 days old; *B* and *C*, fœtuses decapitated at 21 days and developed *in utero* to 28 days; *D*, a 21-day rabbit fœtus, showing the size of the fœtus at the time of the operation

fœtal pituitary in the rabbit on the total fat content of the fœtal liver.

Five rabbit fœtuses were decapitated (using the method described by Jost[3]) to remove the fœtal pituitary gland. The operation was performed between the twentieth and twenty-first day after mating, and the headless fœtuses were left within the uterus to continue growing. After a further seven to eight days of intrauterine development the fœtuses and the litter mates were removed by Cæsarian section, giving a total of five decapitated fœtuses and fifteen litter mate controls for study. The weights of the operated fœtuses were determined and compared with the headless weights of the control fœtuses.

The liver was dissected from all fœtuses and the fats extracted with ether and expressed as a percentage of the dry weight of the liver.

It was found that although the decapitated fœtuses were very slightly smaller by weight than the headless controls, this difference was not significant. Fig. 1 shows two 28-day fœtuses which were decapitated at 21 days, compared with a 28-day litter mate control; the small fœtus is 21 days old and shows the size at the time of decapitation.

Table 1 shows the results of the estimation of liver fat.

Table 1. TOTAL FAT OF LIVER OF DECAPITATED AND CONTROL RABBIT FŒTUSES

Fœtuses	Age at death	No.	Total liver fat (per cent of dry weight)	± *S.E.*
Controls	28–29 days	15	41·3*	± 1·5
Decapitated (at 20–21 days)	28–29 days	5	49·4*	± 2·3

* This difference is significant. $P < 0{\cdot}01$.

These results demonstrate that the operated rabbit fœtus had a significantly greater content of fat in the liver than the controls. This effect is likely to be due to the removal of the fœtal pituitary, and the work of Jost[2] suggests that the effect may be mediated secondarily through the fœtal thyroid.

These findings, together with those of Jost[2], suggest that the increase in fat noted by Angevine[1] in the human anencephalic fœtus and confirmed in this investigation is an endocrine effect resulting from the hypofunction of the fœtal pituitary and possibly other endocrine glands.

It is of interest in this connexion to note that a recent investigation[4] showed that the thyroids of two anencephalics showed the ability to concentrate iodine and make thyroxine.

I am indebted to Profs. E. W. Walls and A. Jost for help and advice in this investigation.

A Neurohypophyseal Principle in the Elasmobranch Pituitary

THE elasmobranch pituitary gland consists of three distinct and largely separate regions (Fig. 1). Two of these, the rostral and ventral lobes, appear to represent the pars anterior of higher vertebrates, while the third, the so-called neurointermediate lobe, consists of intimately interdigitated neural and intermediate tissue[1]. Scharrer[2] has described a pre-optico-hypophyseal system in *Scyliorhinus stellare*, and our own unpublished histological studies on this system in *S. caniculus* have demonstrated the presence of material which is Gomori-positive, aldehyde–fuchsin-positive and stains by the performic acid–alcian blue technique of Adams and Sloper[3]. However, in spite of the undoubted existence of a neurohypophyseal system in elasmobranchs, evidence for the existence of the oxytocic and vasopressor principles characteristically present in the mammalian neurohypophysis is conflicting[4-8]. The investigation reported here attempts to resolve the discrepancy between the morphological and physiological findings.

Pituitary glands were removed from freshly killed *Squalus acanthias*, *Scyliorhinus caniculus*, *Raia clavata*, *R. batis* and *R. naevus*, separated into their constituent lobes, and dried in acetone. The resulting powders were extracted with 0·25 per cent acetic acid by the standard method for ox posterior lobe pituitary, and assayed against international standard posterior lobe pituitary powder, 'Pitocin', or 'Pitressin' (Parke Davis), for oxytocic activity, by the rat uterus and milk ejection methods of Holton[9] and Cross and Van Dyke[10] respectively, for antidiuretic activity[11], and for vasopressor activity[12]. By these means oxytocic, milk ejection and antidiuretic activities were found

Fig. 1. *Scyliorhinus caniculus*. Table 1. OXYTOCIC AND ANTIDIURETIC ACTIVITIES OF ELASMOBRANCH NEUROINTERMEDIATE LOBE EXPRESSED AS M.U./MGM. ACETONE-DRIED POWDER

Species	Oxytocic activity (isolated rat uterus)	Oxytocic activity (rabbit milk ejection)	Antidiuretic activity (conscious rat)	Milk ejection oxytocic activity expressed as a percentage of rat uterus oxytocic activity	Antidiuretic activity expressed as a percentage of oxytocic activity	
					Rat uterus	Milk ejection
Squalus acanthias (pregnant ♀♀)	17·0	45	1·3	265	7·6	2·8
Scyliorhinus caniculus	13·2 ± 1·0	60	0·5	450	3·8	0·8
Raia clavata	17·0	60	0·13	353	0·7	0·2
R. batis	7·7 ± 0·5	35	0·6	454	7·7	1·7
R. naevus	10·0	—	0·5	—	5·0	—

to be present and were preferentially distributed in the neurointermediate lobe. No pressor effects were obtained from the amounts of material injected. Table 1 gives a brief summary of some representative results drawn from an extensive series of assays. It is evident from this that:

(1) The potencies, expressed in m.u./mgm. of dried powder, are low compared with international standard posterior lobe pituitary powder. These low figures are largely accounted for by the fact that elasmobranch neurointermediate lobe is composed mainly of intermedia tissue (Fig. 1).

(2) Very little antidiuretic activity is present in any of the elasmobranch powders. This confirms the earlier pioneer work of Heller[7] on dogfish and skate. Values are always below 9 per cent (average 5·1 per cent) of the rat uterus oxytocic figures, and below 2·8 per cent (average 1·2 per cent) of the corresponding milk ejection potency.

(3) The oxytocic activity of neurointermediate lobe powder is always approximately three times as high when measured by the rabbit milk ejection method as when measured by the rat uterus method.

The pharmacological properties of elasmobranch neurohypophyseal extracts have been studied in detail and have been shown to correspond closely to those of their mammalian counterparts. For example: All activities are stable in an acetone-dried powder, and as extracts in 0·25 per cent acetic acid; the oxytocic activity is unaffected by crystalline pepsin, crystalline trypsin, or atropine; the oxytocic and antidiuretic activities are destroyed by 0·01 *M* sodium thioglycollate at room temperature, by warming with 0·1 *N* sodium hydroxide, and by ultraviolet light; the oxytocic activity is destroyed by crystalline chymotrypsin. In 'four-point' rat uterus assays there is no significant deviation from parallelism between the assessed dose response curves for the elasmobranch agent and 'Pitocin'. In contrast to acetylcholine, and extracts of elasmobranch indifferent brain and hypothalamus, and in common with beef oxytocin, the elasmobranch neurointermediate lobe extract shows a long latency of action on the isolated rat uterus.

By definition, the ratios between milk ejection activity, rat uterus oxytocic activity and antidiuretic activity of international standard posterior lobe pituitary powder are 1 : 1 : 1. Analysis of all our results shows that these ratios in the elasmobranch material approximate to 3·5 : 1 : 0·05. A survey of the relevant literature demonstrates that this low titre of antidiuretic hormone relative to oxytocin is unique among the vertebrates so far examined. It seems unlikely that these discrepant ratios in elasmobranchs are due to contaminating inhibitors or activators since both 'Pitressin' and 'Pitocin', when added to elasmobranch neurointermediate lobe extracts inactivated by ultra-violet light, assay at their normal value, and there is the same high degree of destruction of all the activities by the various treatments described above. Recent work on oxytocin analogues has shown that single amino-acid substitutions alter the biological properties of the molecule, and analogues have already been synthesized which are more potent in releasing milk than in causing the rat uterus to contract when assayed against posterior lobe pituitary powder[13].

The antidiuretic activity of the elasmobranch materials examined is approximately 5·0 and 1·2 per cent of the corresponding values for oxytocic activity obtained by rat uterus and milk ejection assays respectively; these percentages approach the intrinsic antidiuretic activity of synthetic oxytocin. In the light of the low antidiuretic potency of the elasmobranch extracts and the discrepant oxytocic activity ratios, it is suggested that the neurointermediate lobe of the elasmobranch pituitary, so far as it is possible to generalize from five species, is exceptional in containing no discrete vasopressor/antidiuretic principle, though an oxytocic substance, not identical with beef oxytocin, is undoubtedly present. Recent work of Pickering and Heller[14], and Sawyer, Munsick and van Dyke[15], has demonstrated the presence of two oxytocin-like substances in the neurohypophyses of a variety of lower vertebrates (not elasmobranchs). Our range of assays is insufficient to say whether or not a similar situation obtains also in elasmobranchs, though if this is afterwards shown to be the case, it does not affect our submission that a modified type of oxytocin occurs in the elasmobranch neurohypophysis and that the vasopressor/antidiuretic hormone is absent.

This work, a detailed report of which will be published elsewhere, was supported by a generous grant from the Nuffield Foundation.

HÆMATOLOGY

Paradoxical Effect of Magnesium Ions on Blood Coagulation

We have recently reported on the delay of whole-blood thrombin generation *in vitro* and *in vivo* which occurs when the concentration of magnesium is raised[1,2]. These results might have been thought to contradict the fact that addition of magnesium is known to enhance clotting of blood of which the calcium content has been lowered by previous passage through a suitable ion exchange column[3].

The inhibitory effect of magnesium on untreated blood has been explained on the basis of a competition between magnesium and calcium in processes where calcium is the more efficient catalyst[4]. We want to suggest that the present apparent contradiction can also be explained on similar lines because the outcome of the competition will depend on the concentration of either ion.

In decalcified plasma, magnesium alone will not restore coagulability. However, when sub-optimal amounts of calcium are added, magnesium will then enhance clotting. This can be understood if one assumes that some part or parts of the clotting mechanism can be activated by calcium alone, and that others can utilize magnesium though as a less efficient catalyst. Thus, if the amount of calcium is sub-optimal magnesium will be calcium-sparing; but if enough calcium is available to serve all clotting processes, added magnesium can then only displace the more efficient catalyst, and its effect will therefore be to retard clotting. Hence, the effect of a given concentration of magnesium on clotting will depend on the calcium concentration. Table 1 shows that with a calcium concentration of 5 m.equiv. per l., 10 m.equiv. per l. of magnesium is inhibitory, and with 2 m.equiv. per l. of calcium, 10 m.equiv. per l. of magnesium activates.

Table 1. Clotting Times (min.) of De-ionized Plasma diluted 10 : 1 with Additive

Ca⁺⁺ (m.equiv. per litre)	Mg⁺⁺ (m.equiv. per litre)			
	—	2	4	10
2	>60	11	12	32·5
3	15			
4	8·5			
5	7·5	7	8	11
6	7			
8	7			
10	7			
15	7	7	8	10
20	7·5			
30	9·5			
40	15			
50	>60			

Blood was taken into an ion exchange blood pack (Fenwall Laboratories, U.S.A.). Plasma was prepared by centrifuging at 1,500 r.p.m. for 20 min. 1 ml. of plasma added to 1 ml. additive in 8 × 75 ml. glass tubes incubated in a 37° C. water-bath. Clotting end-point was taken as the time when tubes could first be inverted without spilling (checked at ½-min. intervals).

As one might expect, with increasing quantities of magnesium the activating effect becomes less, and the inhibitory effect more pronounced. 2 m.equiv. per l. of magnesium will restore the clotting time of a calcium-poor plasma (2 m.equiv. calcium per l.) almost to normal, but will not inhibit the clotting of plasma containing normal amounts of calcium. On the other hand, 10 m.equiv. per l. of magnesium shows only little activation of the calcium-poor plasma, but marked inhibition at physiological levels. Furthermore, with the larger amount of magnesium the inhibition is diminished when calcium is present in high concentrations—bordering on those where calcium itself starts to become an inhibitor. This again illustrates the competition which exists between calcium and magnesium for clotting factors.

(This self-inhibitory effect of high calcium concentration is well-known, and has been explained[4] on a mechanical basis. The divalent calcium ion supposed to link two protein molecules will fail to form this bridge when it is in excess because too many of these molecules will have a calcium atom of their own.)

Electrophoretic Patterns of Haptoglobins in Apes

The haptoglobin serum groups are Mendelian characteristics of normal people as are blood groups. Two common genes, Hp^1 and Hp^2, have been found and their frequencies in all white peoples studied have been about 0·4 and 0·6 respectively[1-7]. Gene Hp^2 seems to be much rarer in Negroes than in Whites[1,5].

The sera of most mammalian species seem to contain haptoglobin, but the only electrophoretic pattern that we have found in domestic and laboratory animals studied resembles closely that of Hp^1Hp^1 (Hp 1–1) people. On account of this observation we have studied blood samples of different primates listed below with the starch gel electrophoresis method described earlier[6].

Macacus rhesus	17 specimens
Macacus radiata	10 ,,
Papio hamadryas	1 ,,
Cercopithecus aethiops	1 ,,
Pan traglotydes	2 ,,

Sera of all apes studied gave the pattern *C* of Fig. 1, which closely resembles the pattern *D* (human Hp 1–1).

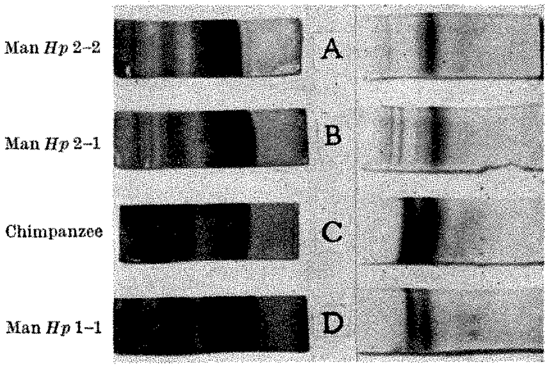

Fig. 1

It thus seems that if there is any haptoglobin polymorphism among *M. rhesus* or *M. radiata* demonstrable by starch gel electrophoresis, the gene giving *Hp* 1–1 like pattern is predominant.

Serum Chromatography on Columns connected to a Common Source of Buffer Gradients

Recently there has been much progress in the separation of serum proteins by column chromatography. The best resolution of the protein components is theoretically obtained by the application of buffer and salt gradients to the column[1]. This principle has been applied during the elution of human serum from modified cellulose anion exchange columns when large numbers of chromatographic peaks were observed[2]. However, this technique is time-consuming, and it is difficult to produce an identical sequence of buffer gradients for each experiment. A modification using a single buffer gradient has been described for the separation of serum components of clinical interest[3], but this method reveals fewer components than the original technique. To overcome these difficulties a method with high resolving power for the simultaneous comparison of sera using the same system of buffer gradients has been developed and investigated.

A chromatographic comparison of human and animal serum on diethylaminoethyl cellulose under the same experimental conditions has not been reported. It was of interest during experiments with bovine serum to compare the results with the behaviour of human serum under identical conditions which were obtained by the simultaneous application to two columns of buffer gradients from the same source.

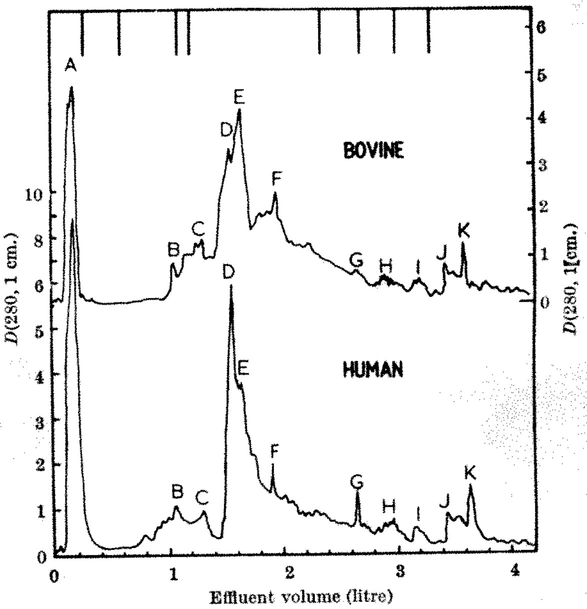

Fig. 1. Elution curves of two sera on diethylaminoethyl cellulose columns connected to the same buffer gradient source. Human serum (lower curve, left-hand ordinate) and bovine serum (upper curve, right-hand ordinate). The ordinates refer to the optical densities of a 1-cm. layer of the column effluent measured at 280 millimicrons wave-length (*D*(280, 1 cm.)). The positions of buffer changes are shown by the upper vertical lines. On both curves there are peaks emerging at similar effluent volumes. These corresponding peaks are labelled alphabetically in order of their elution

Experimental details were as follows: two columns (60 cm. × 2·5 cm.) were packed to a height of 25 cm. with diethylaminoethyl cellulose which contained 0·77 m.equiv. of ionizing groups per gm. They were mounted at different positions above an automatic fraction collector in a 4° C. room. The proteins of pooled bovine serum (100 ml.) and pooled human serum (100 ml.) were separated by gradient elution chromatography on separate columns essentially as in the original method[2], but common buffer gradients were generated for both columns in the same 2-l. reservoir connected to a 250-ml. conical flask with magnetic stirrer as mixing chamber. The common solution feed-tube was divided into separate inlet tubes for each column by a Y-shaped glass tube. Eluting solutions were forced through this system under regulated air pressure to give a flow through each column of about 20 ml./hr. Solutions used in the buffer reservoir were (*a*) 0·005 *M* sodium phosphate of *p*H 7; (*b*) 0·02 *M* sodium dihydrogen phosphate; (*c*) 0·03 *M* sodium dihydrogen phosphate; (*d*) 0·05 *M* sodium dihydrogen phosphate containing 0·02 *M* sodium chloride; (*e*) 0·05 *M* sodium dihydrogen phosphate containing 0·05 *M* sodium chloride; (*f*) 0·05 *M* sodium dihydrogen phosphate containing 0·1 *M* sodium chloride, and (*g*) 0·05 *M* sodium dihydrogen phosphate containing 0·5 *M* sodium chloride. Effluent fractions of about 10 ml. were collected. The volumes were accurately measured, and the ultra-violet absorption in a 1-cm. cell at 280 mμ was determined for each fraction.

Fig. 1 shows the elution curves of human and bovine serum. During the initial buffer gradient the sharp γ-globulin peak (*A*) emerged. It was followed by a large number of peaks which could be classified into 10 groups (*B*–*K*) each containing chromatographically distinct peaks.

Freeze-dried protein from each fraction was dissolved to give a 2 per cent solution which was examined by paper electrophoresis in 0·075 ionic strength veronal buffer of *p*H 8·6 followed by protein staining with bromphenol blue dye. As previously noted by Sober *et al.*[2], some difficulty was encountered in attempting to classify the results solely on the basis of mobilities. However, the patterns of the different groups showed the following distinct features: (*A*) protein only in the γ position, (*B*) protein in the β and γ regions, (*C*) protein in the γ position, (*D*) and (*E*) protein in the α and albumin regions, (*F*) major protein in the albumin region, (*G*) and (*H*) protein in the α, β and albumin positions, (*I*), (*J*) and (*K*) protein in the α and β regions. In addition, all the fractions showed some protein in the γ-globulin area of the paper strips. It was noticed that corresponding peaks had similar electrophoretic composition and emerged at the same effluent volumes from both sera.

This suggests the possible identity of the components from both sera and shows the reproducibility obtained on two columns by this method. The differences in the heights of corresponding peaks of the two sera probably reflect the known species differences in the electrophoretic composition of these sera.

The results suggest that this method may be useful for the comparison of different samples of animal sera. These sera are commercially important in the production of antibodies and as tissue-culture nutrients. Large-scale separation of these proteins on a battery of columns connected to the same buffer source may have advantages over single large-column operation, since the homogeneous packing, handling, regeneration, thermal and mechanical stability, and vertical space requirements may be better in the former case. Analytical applications for the comparison of pathological sera with a normal control serum may also be of interest, as modified cellulose columns have recently been described for the separation of myeloma proteins[3], rheumatoid factor[4], and lupus erythematosus factor[5] from human serum.

The present work is part of a project on the chromatography of high molecular weight substances. The help and support of the Director of the Commonwealth Serum Laboratories during this work is gratefully acknowledged.

Decrease of the Copper Bands of *Helix pomatia* Hæmocyanin

A study of the absorption spectra of α- and β-hæmocyanin of *Helix pomatia* indicated that the copper bands of α-hæmocyanin, with their maxima at 346 and 580 mμ, are not quite reproducible[1]. As a continuous decrease of the copper-bands was liable to occur, the extinction of hæmocyanin preparations has been followed over several months.

The blood of several snails was collected and centrifuged during 20 min. at 10,000 r.p.m. in a water-cooled Pirouette (Phywe, Göttingen, Germany). Samples were treated as quickly as possible in various ways and stored at 4° under toluene in well-stoppered flasks. Care was taken to ensure full saturation with toluene during the whole procedure. The extinctions were measured in a Beckman *DU* spectrophotometer at 346 and 278 mμ on aliquots, immediately after dilution with a saturated borax buffer of *p*H 9·18. At this *p*H the contribution of light scattering to the total extinction is practically negligible[2].

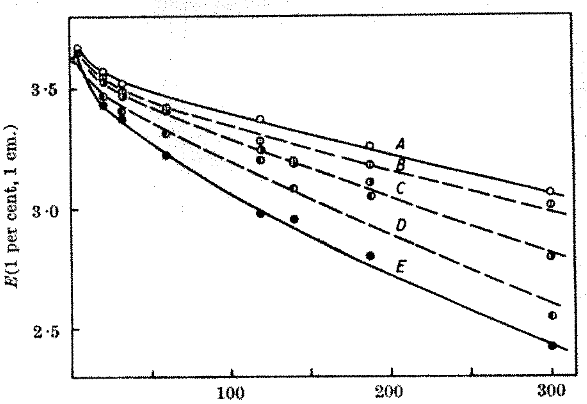

Fig. 1. The decrease during storage of the specific extinction coefficient of *Helix pomatia* hæmocyanin at 346 mμ

The specific extinction coefficients were calculated for the copper band at 346 mμ as a function of *E*(1 per cent, 1 cm.) = 14·16 at 278 mμ. As Fig. 1 shows, the extinctions gradually fall off, starting from the same value. The decrease is most pronounced for blood precipitated three times with ammonium sulphate (*p*H 5·3). The precipitate was dissolved in 0·1 *M* sodium acetate buffer, *p*H 5·7, after the first and the second precipitation. The third time it was stored with the supernatant solution (*E*). The drop of the extinction is smaller when this triple precipitation is followed by dialysis during one night against water at 4°, the precipitate having been dissolved in 0·1 *M* NaOAc, *p*H 5·7 (*C*). The protection is rather good after filtration of 100 ml. of blood on 10 gm. of activated charcoal ('Norit') (*B*) and very small after extraction with 1 volume of chloroform (*D*). Two ultracentrifugations (Spinco Model *L*, rotor No. 30, 2½ hr., 4°, 78,410*g*), followed by dialysis during 48 hr. against water (*A*), yielded good protection, comparable to the charcoal treatment (*B*).

The general shape of the copper bands remains unchanged, as indicated by a comparison of freshly prepared blood with some samples after 300 days storage. It is to be noted further that the extinction coefficients at 580 mμ follow exactly the corresponding values at 346 mμ (Table 1).

Table 1. RELATIONSHIP BETWEEN THE SPECIFIC EXTINCTION COEFFICIENTS OF THE COPPER BANDS AFTER 300 DAYS STORAGE (DILUTION WITH A SATURATED BORAX BUFFER, *p*H 9·18, 20° C.)

Treatment	*E*(1 per cent, 1 cm.) 346 mμ	*E*(1 per cent, 1 cm.) 580 mμ	E_{346}/E_{580}
D	2·55	0·154	16·5
C	2·79	0·171	16·4
B	3·01	0·179	16·8
A	3·06	0·185	16·5

In order to see if α- and β-hæmocyanin behave in a similar way, preparations of total hæmocyanin, made from blood collected during different years and stored under toluene at 4° as an ammonium sulphate precipitate for varying periods, were separated into the two proteins. Extinction coefficients at 346 mμ, determined at *p*H 9·18, are given in Table 2. For β-hæmocyanin four values out of five are very near 2·89. A high value of 3·30 was obtained on a β-preparation, prepared as quickly as possible from fresh blood. The extinction coefficients of some α-hæmocyanin preparations, stored under similar conditions, range from 1·78 to 2·61.

Table 2 SPECIFIC EXTINCTION COEFFICIENTS OF THE COPPER BAND AT 346 Mμ (PURIFIED PREPARATIONS, DILUTED WITH A SATURATED BORAX BUFFER, *p*H 9·18, 20° C.)

Preparation	Year of collection	Protein concentration (per cent (w/v))	*E*(1 per cent, 1 cm.)
β-Hæmocyanin	1952	0·1060	2·98
	1956	0·321	2·88
	1957	0·0563	2·90
(very fresh)	1957	0·0399	3·30
	1959	0·281	2·79
α-Hæmocyanin	1952	0·240	1·78
	1956	0·397	2·20
	1956	0·334	2·58
	1957	0·100	2·60
	1957	0·202	2·07
	1958	0·236	2·61
	1959	0·194	2·21
	1959	0·156	2·10

These observations clearly establish the parallel decrease of the copper bands of *Helix pomatia* hæmocyanin under ordinary storage conditions, β-hæmocyanin changing more slowly than α-hæmocyanin. To explain the decrease a bacterial action may well be ruled out, as the effect is highest in the presence of half-saturated ammonium sulphate. An organic substance, possibly aromatic, which is salted out by ammonium sulphate, could be responsible for this spectral decrease. Evidence has indeed been given for the presence of phenolic amines, for example tyramine, in the blood of some cephalopods[3].

Related observations have been made on the oxygen binding of hæmocyanins. A preparation of *Limulus polyphemus*, stored for several months under half-saturated ammonium sulphate, showed a 30 per cent decrease of the absorption band in the visible, which was accompanied by a 26 per cent lowering of the oxygen-binding capacity[4]. The hæmocyanin of *Helix pomatia* has further been reported to show during storage at − 10° a change from the sigmoid oxygenation curve to a rectangular hyperbola[5].

The ratio, however, of α- and β-hæmocyanin was completely normal in the preparations *A* to *E* after 300 days storage, as determined by dissociation tests in a Spinco ultracentrifuge model *E* and *M* sodium chloride at *p*H 5·8.

The antigenicity moreover of some hæmocyanin solutions, kept under toluene at 4°, did not undergo any noticeable change after ten years[6].

In conclusion it may well be stressed that the usual way of storing hæmocyanins as an ammonium sulphate precipitate, without any other treatment, proves to be the least satisfactory, if properties connected with the oxygen-binding sites are to be studied.

We wish to thank the Nationaal Fonds voor Wetenschappelijk Onderzoek for a postdoctorate fellowship to one of us (K. H.) and for several grants towards the expenses of this investigation.

PLANT PHYSIOLOGY

Vitamin E and Flowering of *Fragaria vesca* L. var. *semperflorens* Duch.

THE development of *Fragaria vesca* L. var. *semperflorens* Duch. is very sensitive to day-length[1]. In short-day conditions the plants do not reach the reproductive stage. Days more than 12 hr. long are required. Short-day treatment also inhibits flower formation of *Fragaria vesca* plants which have previously reached the flowering stage in long-day conditions. During a season in the open field, the number of flowers found on such flowering plants varies according to the day-length as shown in Fig. 1. A maximum of flowers is found in the inflorescences growing during August–October, which have been initiated during June–July, in the longest days.

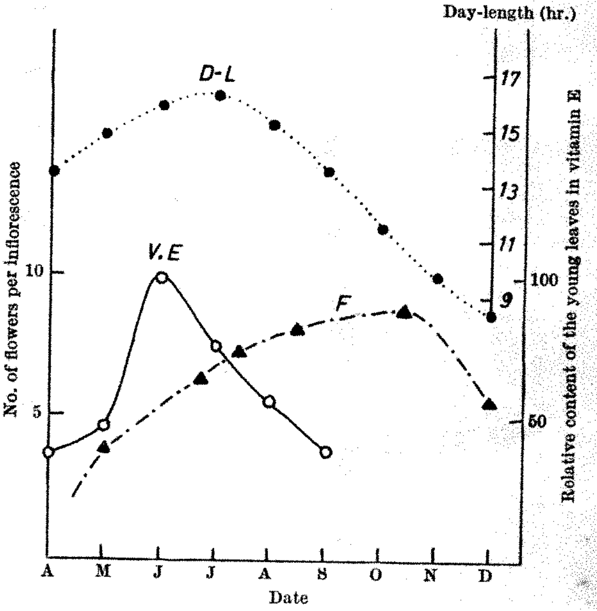

Fig. 1. Relations between day-length, number of flowers per inflorescence and vitamin E content of the young leaves in flowering plants of *Fragaria vesca* L. var. *semperflorens* Duch. (for explanations, see the text; *D-L*, day-length; *V.E.*, vitamin E content; *F*, number of flowers per inflorescence)

On the other hand, in some experimental conditions, runner plants of *Fragaria vesca* have been shown to improve their flowering capacity when vitamin E is applied externally to the leaves in low concentration[1]. It seemed, therefore, interesting to investigate the two following points: (1) Is the vitamin E content of *Fragaria vesca* plants grown in 8-hr. day (remaining vegetative) different from that of plants grown in 16-hr. day (beginning to form flowers)? (2) Is the vitamin E content of flowering plants related in some way to their flowering intensity?

Vitamin E was measured by the method of Meunier and Vinet[2] in the unsaponifiable fraction of the leaves extracted as described by Sironval[1]. The separation of the vitamin was obtained on 'Floridin *XS*' prepared following Kjölhede's method[3].

Table 1, measurements 1–3, answers the first question. The measurements were made in adult leaves of *Fragaria vesca* plants grown in 8-hr. days (remaining vegetative) or in 16-hr. days (beginning to form their first flowers). The temperature was maintained constant (20° C.) for measurement 1. Measure-

Table 1. Effect of Day-Length on the Vitamin E Content of the Adult Leaves of *Fragaria vesca* L. var. *semperflorens* Duch. (per γ in 100 mgm. of the Unsaponifiable Fraction)

Measurement No.	Temperature	8-hr. day	16-hr. day
1	20° C. constant	219	430
2	variable	255	490
3	variable	202	480
4	variable	185*	420

* This series has first been grown in long-days. It was transferred to short-days at the flowering stage. The measurement is done 2 months after the transfer (see text).

ments 2 and 3 were made on plants grown in the open field. It appears from Table 1 that the content of vitamin E per 100 mgm. of the unsaponifiable fraction is regularly about twice as high in long-days than in short-days. Calculated on a dry-weight basis, the recorded difference is still more marked.

Measurement 4 of Table 1 is concerned with the second question. Flowering plants grown in 16-hr. day were transferred to 8-hr. day. They were compared to the control remaining in 16-hr. day. After the transfer to short-day the flowering intensity strongly diminished, in accordance with previous observations[1]. Within two months after the transfer, the vitamin E content of the adult leaves of the transferred plants dropped to about half, while the content of the control remained constant.

Another observation concerned with the second question is recorded in Fig. 1, which gives for flowering plants in the field the normal variations of the vitamin E content of the young leaves near the apex (4 cm. high) during the year 1958. These variations are compared with the variations of the flowering intensity and those of day-length. It is seen that the vitamin E content is first low at the beginning of the spring; it rises rapidly until June, and falls after that. The maximum in June corresponds approximately to the maximum of day-length. It appears just before the maximum rate of flower initiation, at the moment of the rapid increase of the number of flowers per inflorescence. This has been found also during the year 1957 (Table 2). However, as shown in Table 2, the seasonal variations of the content in vitamin E is less evident in adult and old leaves than in young ones. The content drops with the ageing of the leaves, as we see when considering the underlined figures of Table 2, which are concerned approximately with the same set of ageing leaves.

It is concluded that the vitamin E content of *Fragaria vesca* leaves is very sensitive to day-length, and that this feature is related in some way to the action of day-length on flower formation. Normal flower formation seems to require a high vitamin E content in the leaves. This is seen not only in experiments with extreme day-length (8-hr. and 16-hr.), but also in ordinary culture in the field. In this last case, the occurrence of a high content in vitamin E in the young leaves surrounding the apex, at the moment of the active increase of flower initiation in June, strongly supports the idea that the vitamin plays a part in the promotion of flowering.

Table 2. Variations of the Vitamin E Content of the Leaves of Flowering *Fragaria vesca* L. cultivated in the Field during the Years 1957 and 1958 (100 for 1957, 62γ per 100 mgm. dry weight; for 1958, 71γ per 100 mgm. dry weight)

Chlorogenic Acid of Lettuce Seeds

The high concentration of chlorogenic acid in lettuce seed has not previously been reported. Fig. 1 compares the ultra-violet absorption spectrum of a methanol solution of chlorogenic acid, 0·02 gm./l., with that of a methanol extract of 1 gm. of lettuce seed made up to 1 litre. The lettuce seed had been extracted continuously with methanol for 16 hr. in a Soxhlet apparatus. Paper chromatography of the extract showed the predominant fluorescent component to be chlorogenic acid. Several other fluorescent components which after elution show the same ultra-violet absorption spectra as chlorogenic acid are also present on the chromatograms. These are probably isomers of chlorogenic acid, but could be other depsides of caffeic acid. Caffeic acid itself is not a major component. Assuming that the compounds which have the same absorption spectrum as chlorogenic acid are isomers and have the same molecular extinction coefficient at 330 mμ, 2 per cent of the weight of the dry seed is chlorogenic acid and its isomers.

In order to investigate the possible role of this large amount of chlorogenic acid, lettuce seeds were germinated for as long as two weeks and the seedlings from 1 gm. of seeds were extracted with methanol.

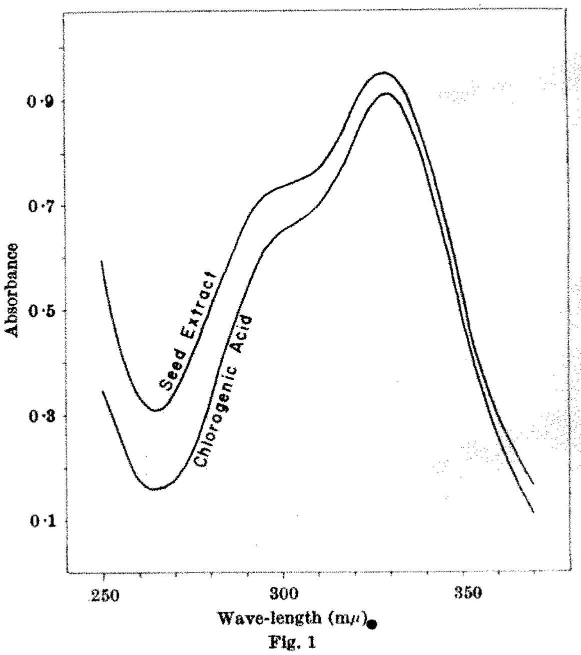

Fig. 1

The total amount of chlorogenic acid did not change during germination. By separating the cotyledons from the seedlings it was shown that the chlorogenic acid remained in the cotyledons of the seedlings with very little, if any, being translocated into the stem or roots. The possibility that chlorogenic acid was actively turning over cannot be ruled out. However, the apparent lack of utilization suggests that chlorogenic acid in lettuce seed may be an end-product which accumulates to a high concentration in the seed, but serves no metabolic function.

The lettuce seed also contains an active polyphenol oxidase as Mayer[1] has shown. Thus, the chlorogenic acid exists in the seed along with a polyphenol oxidase without interacting even in the wet, imbibed seed where metabolic processes are occurring. Mason[2] has suggested theoretically that polyphenol oxidases act as hydroxylating enzymes *in vivo* and assume their oxidase activity only when the cell is broken. According to this view the polyphenol oxidase which destroys the chlorogenic acid when the cell is broken might be involved in its formation and accumulation in the seed.

Nitrogen Feeding of Apple Trees by Post-Harvest Urea Sprays

In the early post-bloom period it is common to spray apple trees with a 0·5 per cent urea solution which, when repeated several times, results in a clear increase of leaf chlorophyll and leaf total nitrogen in comparison with leaves of unsprayed trees[1]. Higher concentrations may cause leaf injury. It seems unlikely that this injury caused in the late autumn would reduce to any extent the total amount photosynthesized during the passing season. This would permit the use of comparatively concentrated spray solutions at that time. The absorption of nitrogen may be proportional to the concentration of the urea solution[2].

Prior to abscission some 40–50 per cent of the total nitrogen of the leaves is re-absorbed by the tree[3]. This nitrogen makes up the whole, or a part, of the nitrogenous reserves which are utilized the following growing season. Apart from securing the normal nitrogen needs of the tree, a large reserve may effect early starting of growth in the spring in comparison with trees of low reserves[4].

As is shown in Fig. 1, a spray in the middle of October with a 4 per cent urea solution has increased the total organic nitrogen content of the leaves by 51 per cent within two days after application. When attention was first directed to urea sprays as a means of supplying apple trees with nitrogen, the registered increase in leaf nitrogen was approximately 15 per cent after four applications[5]. Fig. 1 shows further that absorbed nitrogen has migrated from the leaves into the tree. By the time of leaf fall (November 12) the sprayed trees had spurs, with developed blossom buds, containing 31 per cent more nitrogen than spurs of unsprayed trees. The corresponding figure for terminal shoots is 16 per cent.

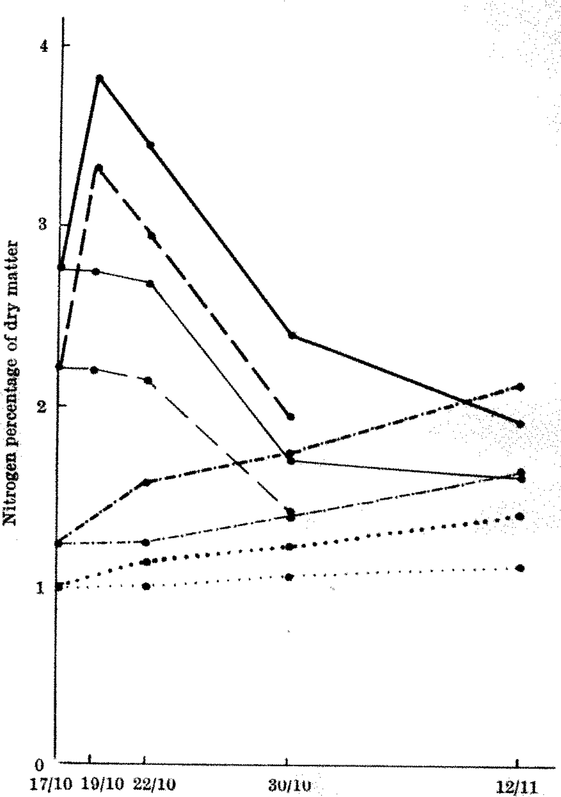

Fig. 1. Nitrogen content of different parts of apple trees sprayed with a 4 per cent urea solution on October 17 (heavy lines), and unsprayed control trees (thin lines). Shoot leaves, ———; spur leaves, — — —; shoots, ...; and spurs, -·-·-·-. All plant parts were washed thoroughly before drying and analysis

The leaf injury caused by the 4 per cent urea spray was some marginal browning of spur leaves and basal shoot leaves, while leaves at the tips of the shoots appeared unaltered.

It is suggested that the amount of nitrogen absorbed by the trees from a single spray might compare to a net intake of 30–40 kgm. nitrogen per hectare. (The amount of leaves in an established orchard is assumed to be of the order of magnitude of 3,000 kgm. dry weight per hectare.) This amount of nitrogen is well above what the trees may be expected to make profitable use of, besides the nitrogen supplied by a normal organic matter metabolism of the soil.

We lack knowledge concerning the responses of apple trees to nitrogen fertilization[6], which is at least partly due to the sources of errors in the experiments carried out. The experience gained during the past autumn, in experiments with the suggested method of nitrogen feeding, seems to promise that accurately known amounts of nitrogen may be introduced into the trees by post-harvest urea sprays. As large effects can be obtained, it would serve profitably in studies on the importance of nitrogenous reserves, as well as in studies on nitrogen metabolism.

RADIOBIOLOGY

Reduction of the Radioactive Content of Milk by a Feeding Procedure

A METHOD for reducing the fall-out content of milk has been investigated. This is a preliminary report on the results obtained in a short-term study in this area. There are to-day commercially available 'grass incubators' which hydroponically germinate various grains to be used as a substitute for fresh pasturage. It is claimed that the product of these incubators fed to cattle on dry lot maintains the cows in a high production of superior-quality milk to an extent which makes the purchase of such incubators economically desirable. The increased use of these feeding systems in this area raised the question to us concerning the effect this substituted diet may have on the radioactive content of milk.

In the experimental work a total of twenty dairy cows was used, all of which had been under the same conditions for several weeks prior to the experiment. The cows were divided into two groups of ten animals each; the control group was kept on natural pasture during the experiment while the experimental group was confined in dry lot and had only incubator-germinated oats as their source of green pasturage. These oats were allowed to germinate for 6 days in the incubators under hydroponic culture and then were fed as intact mats of seed and shoot to the cows. Cultivation was according to the manufacturer's directions (Buckeye Incubator Co., Springfield, Ohio). Each cow in the experimental group was fed 20 lb. of incubator feed daily. Both groups were fed their usual hay and grain diet. Equal aliquots of milk were taken from each cow at each milking and pooled into a weekly sample for each group. Thus the analyses for radioactive content were made on weekly aliquots of pooled samples from each of the two groups. The total volume of each sample was measured and a 4-l. aliquot evaporated to 2 l. in a sand-bath. The residual liquid was counted for cæsium-137 and potassium-40 content. The counting was performed with an 8 in. × 4 in. sodium iodide (Tl) crystal feeding into a 256 channel analyser (Vanderbilt University Low Level Whole Body Counting Facility supported by: United States Atomic Energy Commission Grant No. *AT* (40-1)-240 and Contract No. *DA*-49-007-*MD*-995 with the Army Medical Research and Development Command). The samples were counted for 1 hr., which made possible net counts for cæsium-137 and potassium-40 in the range 500-3,000 counts. The results are given in Table 1 as net counts which are the gross counts less background. Background was run on a solution of 12·5 gm. potassium chloride in 2,200 ml. distilled water, to approximate the potassium content of milk.

The cæsium-137 counts in all of the seven weekly groups were significantly lower (more than twice the standard error of the difference) than the controls, with an average reduction of 38 per cent. The potassium-40 counts were significantly different only in the first and third weekly samples and fail to show a consistent trend.

The differences in the cæsium-137 counts between the control and the experimental groups becomes more significant when we consider that the substituted incubator feed comprises only a part of the total diet. A more detailed study is proposed.

We are indebted to Mr. George Ivey, of Little River Farms, Alpharetta, Georgia, for supplying the cattle and dairy facilities for this pilot study. Also, we wish to express our appreciation to Dr. George R. Menelly and Dr. Robert T. Lagermann for use of the 'Low Level Whole Body Counting Facility' at Vanderbilt University and to Mr. William Van Willis for his technical assistance.

Radiosensitivity of the Pre-irradiated Yoshida Sarcoma

ACQUIRED radioresistance of cancer has been discussed clinically and experimentally by several authors[1-5]. The various opinions concerning its mechanism may be summarized as follows: (1) selection of cancer cells; (2) induction of mutation and its adaptation; (3) connective tissue response or tumour bed response. Experimental confirmations are less pronounced than clinical observations. One[1,2] of the recent experiments showed development of radioresistance using repeated frequent X-ray irradiations of intramuscular implantation of Ehrlich carcinoma, whereas others[3] noticed no change of radiosensitivity following frequent whole-body γ-ray irradiations of mice bearing Ehrlich ascites carcinoma. The results of the latter may be due to insufficient dose to develop a radioresistance.

It seemed, therefore, of interest to conduct an experimental study of radiosensitivity on the hypothesis that the most suitable way to induce radioresistance is to expose tumour cells to such a dose of irradiation that only a few cells could survive. By repeating this procedure to successive generations radioresistance might be obtained.

The experiment was initiated in 1955 using the Yoshida sarcoma. Mixed-bred rats weighing about 100 gm. were used. For the first transfer generation, 5×10^6 tumour cells were transplanted into the peritoneal cavity, and 4 days later this tumour-bearing rat received a whole-body X-irradiation of 1,000 r. Physical factors were 185 kVp., 6 m.amp., half-value layer 0·76 mm. of copper, focus-peritoneal cavity distance 23 cm. and dose-rate 74·1 r./min. in air. 1 hr. later, the same number of tumour cells was transplanted from this rat into the peritoneal cavity of the other rats to make the 2nd generation. After the proliferation of tumour cells at the 2nd generation had occurred in the peritoneal cavity, whole-body irradiation was repeated. 1 hr. later the same number of tumour cells from the 2nd generation rat was transplanted intraperitoneally, making the 3rd generation. Thus, repeated irradiations were carried out up to the 94th transfer generation. The dose was 1,000 r. each for the tumour-bearing rats of the 1st to 31st generation, and 2,000 r. each for those of the 32nd to 94th generation. The tumour cells of the pre-irradiated line were given an integral dose of 87,480 r.

X-ray irradiation of 2,000 r. appeared to be an almost lethal dose for the tumour cells of this type. Five to fifteen rats were used for each transplantation following irradiation. Those transplantations frequently failed. When successful, 7–18 days were required for tumour cell proliferation in the peritoneal cavity after transplantation. In the non-treated control line, on the other hand, 3–4 days were sufficient for the proliferation. Judging from the results[6] of a single cell inoculation of the Yoshida sarcoma into the peritoneal cavity, it is assumed that a few tumour cells remain to proliferate after X-irradiation of 2,000 r.

In order to compare the radiosensitivity of the tumour cells of the pre-irradiated line with that of the non-irradiated line, the cells of both sublines were transplanted subcutaneously in the right shoulder of rats. The tumour regression of both lines following local irradiation with 1,000 r. was studied. The factors of the irradiation were 185 kVp., 6 m.amp., half-value layer 0·76 mm. of copper, focus-tumour distance 13 cm., radiation field 4 cm. in diameter and dose rate 232 r./min. in air. The growth-rate of the tumours was studied by measuring size of tumours, regarding them as ellipsoids in shape. No difference was observed between two sublines. The grade of tumour-regression was higher for the pre-irradiated line than for the non-irradiated line following local irradiation with 1,000 r. This characteristic remained unaltered for 4 months without being exposed to X-rays. The mean values of the tumour size of both lines are shown in Fig. 1. Regression curves were statistically determined and significant difference was found between both sublines. The rate of cure of the subcutaneously transplanted tumours of the pre-irradiated line following local irradiation was significantly higher than that of the non-irradiated line.

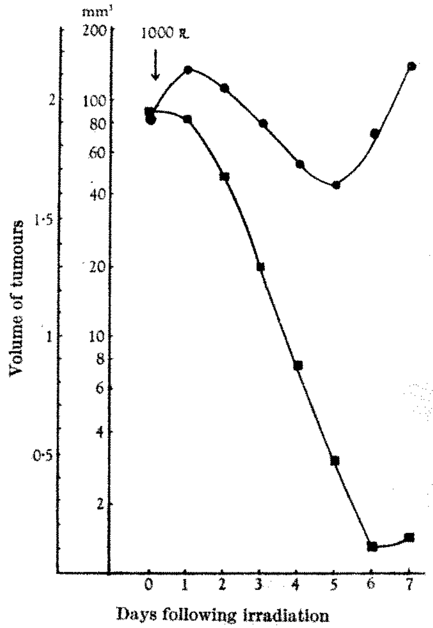

Fig. 1. Changes in volume of subcutaneously implanted tumours following local irradiation with 1,000 r. ●—●, Non-irradiated control line ($y = 1{\cdot}73514 - 0{\cdot}200679\,(x - \bar{x}) + 0{\cdot}00752355\,(x - \bar{x})^2 + 0{\cdot}0159303\,(x - \bar{x})^3$). ■—■, Pre-irradiated line ($y = 0{\cdot}860190 - 0{\cdot}459041\,(x - \bar{x}) + 0{\cdot}0155764\,(x - \bar{x})^2 + 0{\cdot}0178113\,(x - \bar{x})^3$)

From these results, it might be concluded that the pre-irradiated line is not more radioresistant, but more radiosensitive, than the control. It is quite conceivable that irradiation itself induces a mutation which increases the radiosensitivity of tumour cells. From the results of this experiment, it may be inferred that some of the homogeneous population of tumour cells may probably have undergone some mutational changes during the repeated heavy irradiations with X-rays and that these mutant cells proliferate as altered stem-cells. One of the biological characteristics of the pre-irradiated line is that tumour cells involved are more radiosensitive than those in the original line. The fact that selection of tumour cells was not observed may indicate that the individual tumour cell is almost equal in radiosensitivity in the Yoshida sarcoma.

BIOLOGY

Transfer of Germ-Cells in *Xenopus laevis*

THE work of Bounoure[1] and Blackler[2] on three anuran species has shown that, in fixed and sectioned material, and after the application of suitable stains, the embryonic sites that contain primordial germ-cells may be recognized at all developmental stages from the fertilized egg to the tadpole. A technique for the transfer of the gonocytes between one embryo and another has been devised as a first step in a genetical analysis of abnormal embryos produced in this department by the transplantation of somatic nuclei into unfertilized eggs of *Xenopus*.

Three stages of development offer the most likely chances of successful transfer. The first of these is at the late blastula stage, in which the primordial germ-cells are localized in the superficial blastocœl floor. Second, at neurula stages, where the cells can be found in the ventral part of the posterior endoderm, and finally, at the stage 40 tadpole (Nieuwkoop and Faber's table[3]) in which the gonocytes are situated at the dorsal crest of the endoderm. Most successful transfers have so far been achieved at neurula stages.

The technique involves the attempted sterilization of the host embryo (though complete sterilization is not absolutely necessary for our purposes) by removal of its germ-cell site, and the replacement of this by the identical site from a donor embryo. Of course it is necessary to ensure that there is no possibility of confusing graft cells with any host germ-cells remaining after an unsuccessful or only partially successful sterilization. In this respect the use of the Oxford nuclear marker, discovered by Elsdale, Fischberg and Smith[4], has proved invaluable. In normal *Xenopus* embryos the nuclei of both somatic and germ-line cells possess potentially two nucleoli, though in some of the cells these nucleoli may be fused. Embryos bearing the mutation affecting nucleolar number possess but a single nucleolus in all nuclei. Thus when normal germ-cells are grafted into 1-nucleolate embryos and the host embryonic gonads later examined in microscopical sections, any cell present the nucleus of which bears two nucleoli must necessarily be of graft origin.

The method of transfer consists in decapsulating host and donor neurulæ in Niu and Twitty solution, excising the posterior endoderm of the host ventral to the archenteric cavity (together with its overlying ventral mesoderm and ectoderm) and replacing it by the same region taken from the donor embryo. The complete obliteration of the wound cuts by ectodermal overgrowth takes a variable time but operated embryos may eventually be transferred to 0·1 Niu and Twitty, in which solution they can be left for a couple of days. About 40 per cent of the operations are successful in that the graft heals in and the host embryo does not develop abnormally.

Results achieved so far have demonstrated clearly the presence in host gonads of grafted germ-cells, though the marker does not allow any conclusion to be reached in terms of 1-nucleolate germ-cells, which may be of host or graft origin. The latest stages to which these results apply at present are metamorphosed frogs in which, in females, the process of oocyte growth has begun.

Thus primordial germ-cells can be successfully grafted from one individual to another. However, it is not sufficient to prove only this point in establishing the technique, for the method is only of practical use if the grafted germ-cells are capable of giving rise to definitive and functional sex-cells. But if they do, then a central question inherent in the germ-cell problem in vertebrates will be settled, namely, as to whether or not primordial germ-cells give rise to definitive gametes. Such a result would be even more unassailable than the striking indications of germ-cell continuity arising from Mintz and Russell's[5] work on mouse embryos. Host animals are at present being reared to sexual maturity with the view of analysing the transfers by breeding, and it is hoped to publish a full account of the technique at a later date.

I wish to thank Dr. M. Fischberg for determining the nucleolarity of the embryos used. The work is being supported by a grant from the British Empire Cancer Campaign.

Dermal Surface of Sheep-skin

In the dermal surface of sheep-skin a natural feature has been noticed, which is the origin of a defect in the appearance of some gloving leathers. During manufacture of leather the epidermis is removed, the exposed surface becoming the 'grain' of the leather, and small dark spots, scattered several mm. apart, occur on the grain surface of some leathers. A spot is illustrated in Fig. 1 (top), which shows the surface of a leather made from an Abyssinian sheep-skin. The rows of dark regions represent

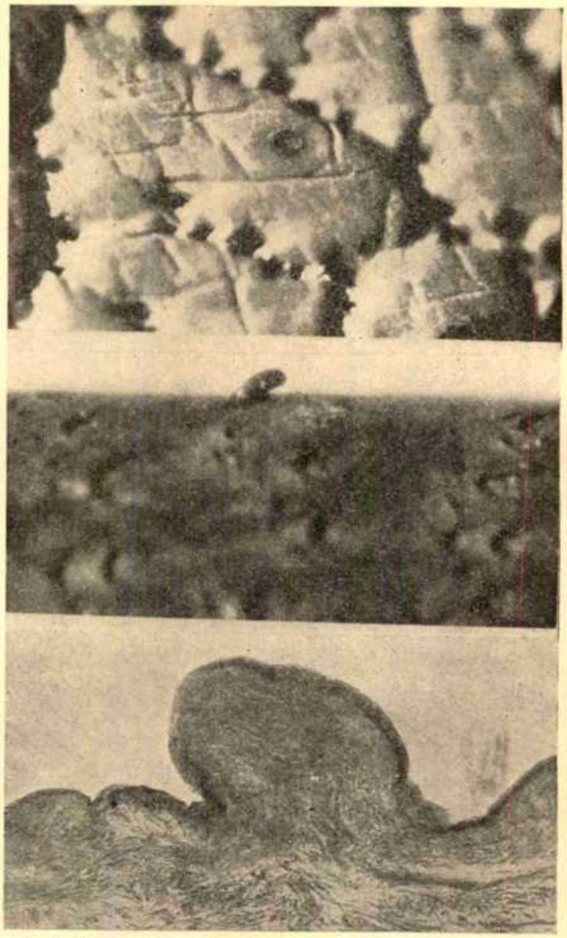

Fig. 1, Top, grain surface of gloving leather showing defective spot between two rows of hair follicle mouths (× *c*. 30); middle, 'tongue' rising from the grain surface of gloving leather (× *c*. 27); bottom, section of the base of a 'tongue' showing it to be a fibrous continuation of the dermis (× *c*. 188) the mouths of hair follicles and an offending spot lies between two such rows. Microscopical examination of cross-sections showed that the spot was not due to diseased or scar tissue, but that the surface connective tissue fibres had been damaged and were, in the leather, stuck together to give a glassy appearance to the spot. The examination of some other leathers of similar type, the origin of which was, however, not precisely known, gave a lead as to the cause of the spots. Fig. 1 (middle) shows a small tongue of tissue rising from the grain surface: the camera is looking along the grain surface so that the tongue is seen in profile. Fig. 1 (bottom) shows the base of a tongue in cross-section: it is fibrous and continuous with the general fibrous tissue of the dermis. The distribution of tongues was similar to that of the spots, and it seems reasonable to conclude that they rub off during processing, leaving the unsightly spots.

Similar spots or tongues have been observed, so far, in leathers from Abyssinian, Cape, Welsh Hill and Australian Merino sheep-skins.

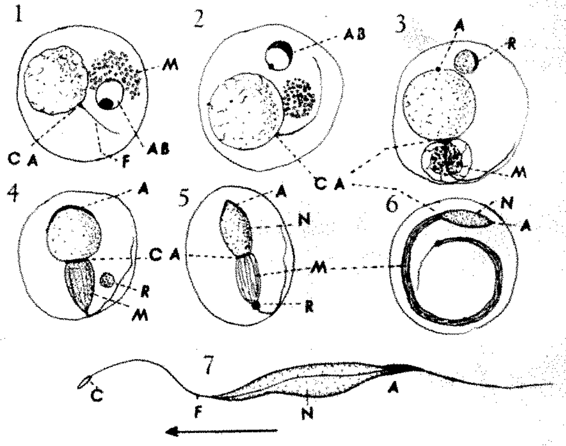
Position of the Proximal Centriole in Flagellate Spermatozoa

What must be one of the most remarkable spermatozoa of Insecta is that of *Lepisma*, as reported by Bowen[1], Nath and Bhatia[2], and Nath[3]. In Fig. 7, this spermatozoon is shown with a centriole (*C*) as its anterior end, connected by a flagellum (*F*), across the nucleus (*N*) to another body (*A*) said to be the acrosome, from which passes back the tail of the spermatozoon. With the acrosome in such a peculiar position, it is difficult to understand how this spermatozoon gets into the egg, always assuming that the acrosome of *Lepisma* takes the usual part in this process. It would seem also that the centriole lies in an unsheltered position, assuming again that this centriole is necessary for initiating the fertilization spindle of *Lepisma*.

We have recently studied the spermiogenesis of another thysanuran, *Petrobius maritimus*, and again are unable to support the interpretation given by Bowen and Nath. Nor do we believe that two insects so closely allied could have spermatozoa basically different in construction. In *Petrobius*, the acroblast (*AB*, Fig. 1) swells up in the early spermatid, producing the acrosome (*A*, Fig. 3), and afterwards flows down as the reject (*R*), which becomes attached for a time to the base of the mitochondrial nebenkern (*M*, Fig. 5). In Fig. 1 the flagellum (*F*) arises from a centriole-like body (*CA*) and curls around inside the cell; the body (*CA*) later forms a flat stainable plate (*CA*) between the nucleus and the mitochondrial middle piece (Fig. 4). This we believe to consist of an anterior centriole, and the centriole adjunct or neck body packing. The acrosome (*A*) lies in its normal position at the head end of the ripening spermatozoon (Fig. 6 *A*). No movement of the centriole forwards has been seen to occur in *Petrobius*. The question of the nature of the plate (*CA*) cannot be solved in such small cells by optical microscopy,



but the formation of the acrosome shown in Figs. 1–3 is quite normal, is within the powers of optical microscopy, and conforms to what has previously been seen in insect spermiogenesis. In some of our preparations, the nucleus between stage Figs. 4 and 5 appeared to have a lateral fold which we were unable to interpret, but which may be Bowen's supposed forward continuation of the flagellum (*F*, Fig. 7). Thus we consider that in Fig. 7, after Bowen and Nath, the anterior bead (*C*) is not the centriole, but is the acrosome (whole or part), whereas the body (*A*) is the adjunct plus the centriole, as has recently been shown to be the case in Orthoptera and Coleoptera by Gatenby and Tahmisian[4], who used the higher powers of the electron microscope.

In stages of spermiogenesis later than Fig. 6, the ripening sperm is seen to have double spiral threads passing down around the flagellum. The sperm is very small; but we could not find any reason to believe, as did Nath, that this spermatozoon is bereft of mitochondrial substance.

In his useful review on the cytology of spermatogenesis, Nath[3] discusses various "atypic flagellate sperms with centriole at the anterior tip". All such cases need re-investigation with the electron microscope, and until this has been carried out, we are inclined to believe that such "atypic flagellate spermatozoa" have no existence in the animal kingdom. Another statement which we find nowadays difficult to accept is that the acroblast directly metamorphoses into the acrosome, that is, "the direct method of acrosome formation" according to Nath and a few previous authors.

So far as we are able to understand, all recent work with the electron microscope supports the view that the acroblast is a pile of lamellæ (or more rarely a series of lamellated vesicles) which in some way concentrates the material included in the acrosome. It does not seem easy to believe that this pile of lamellæ changes into a globular electron translucent acrosome. On the contrary, the lamellæ always seem to be rejected as the Golgi remnant.

References to a centriole at the anterior end of the spermatozoon occur sporadically in the immense literature of the optical microscopy of animal spermiogenesis; but such recent electron microscopists as Burgos and Fawcett[6], Grassé, Carasso and Favard[7], Afzelius[8], Yasuzumi and Tanaka[9], Gatenby and Dalton[10], Gatenby and Tahmisian[4], who worked on mammals, molluscs, insects, oligochætes or seaurchins, all found the proximal centriole in its normal post-nuclear position in the neck of the spermatozoon.

Mitochondria of Goldfish, *Carassius auratus*

The metabolism of mitochondria of poikilotherms acclimatized at different temperatures has not been studied, though such studies have been made on rats[1,2]. The mechanisms of adaptation to cold and warm temperatures in a poikilotherm may be different from those of a homoitherm due to the presence of a temperature-regulating centre in the latter. Hence, mitochondria from livers of goldfish, *Carassius auratus*, acclimatized at 10° and 30° C. were isolated to study their oxidative phosphorylation. The following account gives the method of isolation and the structure of mitochondria of the liver of unacclimatized goldfish.

The liver was placed in ice-cold 0·25 *M* sucrose solution immediately after its removal from the goldfish. All the following steps for the isolation of mitochondria were conducted at 0°–2° C. 2 gm. of the liver were homogenized in 10 c.c. of 0·25 *M* sucrose (buffered at *p*H 7·4 with *tris* buffer and containing 0·001 *M* versene) by fifteen up-and-down strokes of a Potter–Elvehjem homogenizer driven at 300 r.p.m. The homogenate was centrifuged at 700*g* for 10 min. in a refrigerated centrifuge to remove the cellular debris and nuclei. Then the supernatant was pipetted out and centrifuged at 14,000*g* for 10 min. to sediment the mitochondria.

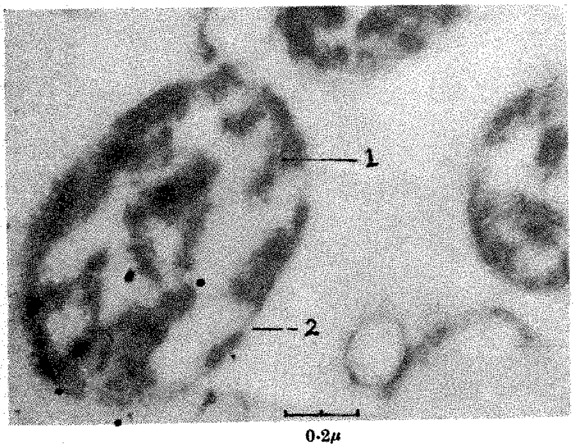

Fig. 1. Electronmicrograph of liver mitochondria of goldfish. 1, Cristæ; 2, double membrane. (× 40,000)

Electronmicrographs of the mitochondrial pellets showed that the mitochondria of the liver of goldfish obtained by the above method were intact (Fig. 1). They were oval in shape, 0·8–1·0μ in length and 0·5–0·6μ in breadth. They had a double membrane and cristæ as in rat liver mitochondria. These mitochondria stained well with janus green.

Oxidative phosphorylation of the liver mitochondria of goldfish acclimatized at 10° and 30° C. will be discussed elsewhere. I am grateful to Prof. C. L. Prosser, Department of Physiology, University of Illinois, for his guidance.

Spread of the Ascidian, *Styela mammiculata* Carlisle

Carlisle[1] described a new species of ascidian, *Styela mammiculata*, which was first taken in 1953, near Plymouth. If, as Carlisle suggested, this is an introduced species, it may be expected to spread. The discovery of numerous specimens on various submerged surfaces and in dredged material in Langston Harbour, Hampshire, during the summer of 1959, is therefore of interest. The species appears to be extending its range rapidly along the south coast of England, and increasing in numbers where already established. We expect it to spread to other sheltered and warm areas of the British and continental coast, either by natural means or by transport on the hulls of ships.

FOREST PRODUCTS

Effect of Moisture Changes on Creep in Wood

During studies on creep in wood under various types of loading over periods of up to several years, it became apparent that changes in the moisture content of the wood while under load markedly influenced both creep-rate and total creep.

To explore this further, small beams of ¾-in. square cross-section were cut from billets of three species, namely, *Eucalyptus regnans* (a hardwood prone to collapse of the cell wall during seasoning), *Eucalyptus pilularis* (a hardwood with very little tendency to collapse), and *Pinus radiata* (a softwood with negligible tendency to collapse). Three moisture conditions were studied, namely, green material maintained in the green state during test, initially green material allowed to dry while under load, and material air-dried to 12 per cent moisture content before loading and maintained at approximately that value during test.

The tests were conducted in a temperature-controlled atmosphere at 25° C. The beams were simply supported and subjected to four-point loading for a period of approximately two weeks. During this time the moisture content of the wood that was allowed to dry had reached a reasonably constant value. Unloaded beams of matched material were used as controls at each moisture condition. The maximum deflexions of the beams relative to the points of support, and the strains in the extreme fibres on the compression and tension faces near the centre of the span, were measured at intervals during test.

The results showed that the relative creep in wood allowed to dry while under load was at least twice that occurring in wood maintained at constant moisture content. Relative creep is defined as the ratio of creep deformation to initial deformation. Further, the relative creep was approximately the same in wood maintained at constant moisture content irrespective of whether it was green or dry. The strains in the extreme fibres were, for all three moisture conditions, much greater on the compression faces of the beams than on the tension faces, the maximum values of extreme fibre strains in both compression and tension being obtained for material drying under load. Similar results were obtained for each of the species tested.

Exploratory experiments have indicated that creep also increases markedly in wood subject to increasing moisture content during test, and that the effect of moisture changes on stress relaxation in beams held at constant deflexion show similar trends (P. U. A. Grossman, personal communication).

In the case of green wood drying while under load a marked difference in total creep and creep-rate has been observed in geometrically similar beams of different sizes. The average drying-rates for the sizes tested differed considerably and it would be expected that the restraints due to moisture gradients in the beams would have been different. Experiments are in progress to determine to what extent the rate of loss or gain of moisture affects the creep-rate and total creep.

In addition, tests have been commenced to determine the effect on creep of small changes in the moisture content of dry wood.

PATHOLOGY

Urinary Selenium and Dental Caries

The suggested direct relationship between urinary selenium concentrations and the prevalence of dental caries in American children[1,2] is not substantiated by an investigation in New Zealand. Until recently, studies on the physiological effects of selenium have been concerned with its toxicity. Later evidence suggests that for some animals, and at certain levels, the element may be classified as essential[3]. Although selenium has not been demonstrated to be essential in man, its suspected role in electron transport may suggest a possible modification of the calcified structures. In New Zealand, the marked improvement in health, weight gain, and reduction of muscular dystrophy in sheep ('white muscle disease') by dosing with selenium[4], suggests there is a minimum level of available selenium in many areas of New Zealand. This evidence warranted an investigation of the supposed selenium–caries relationship.

Analytical data obtained in this investigation, and other work to be published elsewhere, indicate the low levels of available selenium.

The investigation was carried out in two rural areas of the South Island. Both areas are of different soil types, one being of yellow-grey and the other of yellow-brown earths. In neither district has selenium deficiency been reported in farm animals.

In South Otago, 39 school boys 5–14 years old were examined for dental conditions, and 31 of similar ages were examined in North Canterbury. The children were life-time residents of their districts.

All dental examinations were carried out by the one examiner (P. B. C.), and were supplemented by bitewing radiographs. 24-hr. samples of urine were collected under parental supervision, from the children concerned. Samples were collected in polythene bottles containing toluene as a preservative. Every practicable care was taken to ensure the reliability of the samples.

Selenium analysis was carried out by a modification of the colorimetric diamino-benzedine method of Luke[5]. Recoveries were of the order of 94 per cent. Readings were made on Beckman model *DU* spectrophotometer.

Selenium was present in all urine samples. In Table 1 the mean values of urinary selenium-levels for both groups are lower than those in the four areas investigated by Hadjimarkos[1,2], and are believed to be indicative of low selenium availability. The difference of the means for the districts is significant at the 99 per cent level of confidence.

Table 1. Distribution of Urinary Selenium-Levels

Urinary selenium (p.p.m.)	Number of male subjects 5–14 years old in :	
	South Otago	North Canterbury
0·00–0·09	2	0
0·10–0·19	18	3
0·20–0·29	13	11
0·30–0·39	5	15
0·40–0·49	1	2
Totals :	39	31
Means :	0·021 p.p.m.	0·030 p.p.m.
Standard deviation :	± 0·009	± 0·008

It has been shown that the rate of urinary excretion is relatively constant, and is quite independent of urinary volume[6]. As the concentration of selenium is a function of the volume excreted, the volume being subject to climate, fluid intake, and other factors, it is felt that a more reliable basis of comparison may be given by the total urinary selenium excreted in 24 hr.

Table 2 gives the amount of selenium excreted by subjects in the two districts in terms of µgm./24 hr. The mean excretions in each district are significantly different at the 98–99 per cent level of confidence.

The percentage of available tooth surfaces decayed and filled was 22·6 at South Otago and 18·8 at North Canterbury. The difference of 3·8 has a standard error of 9·8. Therefore, the difference is not significant.

There was no correlation between the proportion of available tooth surfaces decayed and filled and the total urinary selenium excreted in 24 hr. (Correlation coefficients were plus 0·019 for South Otago, and plus 0·06 for North Canterbury. Standard errors of the correlation coefficients were 0·16 and 0·16, respectively).

Table 2. SELENIUM EXCRETED IN μGM./24 HR.

Selenium (μgm./24 hr.)	Number of male subjects 5–14 years old in: South Otago	North Canterbury
0–9	5	1
9·1–18	21	10
18·1–27	9	11
27·1–36	3	6
36·1–45	0	1
45·1–54	0	0
54·1–63	1	2
Totals	39	31
Means	17·0 μgm.	23·7 μgm.
Standard deviation	± 9·8	± 12·2

In this investigation the significant difference in selenium excretion between groups was not associated with any significant difference in caries prevalence.

This investigation was carried out as a project of the dental research unit of the Medical Research Council of New Zealand. The assistance and advice of Captain F. L. Losee (D.C.), U.S.N., is gratefully acknowledged.

Cementing Substances in Metastasizing and Non-Metastasizing Transplantable Tumours in Mice

VERY little is known about whether, or how far, the condition of intercellular cementing substances as present in the tissue of a growth may be responsible for local invasion and for metastasis[1,2]. The situation is all the more complex as neoplastic cells may even themselves produce polysaccharides[3], which are considered to be the fundamental chemical constituents of the intercellular cement. The condition of the cementing substances in 13 transplantable tumours in mice have been studied in this laboratory. Results are summarized in Table 1.

Primary tumours were fixed in fluids containing alcohol, formalin and picric and acetic acids, preferably at low temperature (Duboscq–Brasil and Gendre). Particular emphasis was placed on selecting non-necrotic portions for microscopical study. Several staining and histochemical procedures for identifying mucopolysaccharides were used, the most useful being the Hale[4,5] and the periodic acid–Schiff reactions. Phloxine and hæmalum were also occasionally used for cytoplasmic and nuclear counterstaining. The latter removes, however, the Hale-positive cement of epitheliomas and should not be employed in neoplasms of this type.

(1) *The ground substance in eight transplantable sarcomas.* The greatest quantity of the Hale-positive material was present in the ground substance of non-metastasizing tumours (see Table 1, 1–4). There was in these tumours also a great amount of alcian-blue-positive material (not given in Table 1). On the other hand, the Hale-positive material was absent in highly and moderately metastasizing tumours (Table 1, 7 and 8); the quantity was intermediate in slightly metastasizing tumours (Table 1, 5 and 6). In other words, metastatic capacity increases when Hale-positive material diminishes. By contrast, the periodic acid–Schiff-positive material was absent in most of non-metastasizing tumours (Table 1, 1, 2 and 3) and present in most of metastasizing tumours (Table 1, 5, 6 and 8). But there were definite exceptions from this rule (Table 1, 4 and 7). These exceptions are most probably due to the technique, which does not prevent a certain degree of extraction of the more soluble components of periodic acid–Schiff.

Digestion by hyaluronidase and metachromatic staining tend decidedly to favour the assumption that Hale-positive material is chemically related to mucopolysaccharides, at least in certain non-metastasizing sarcomata.

(2) *The intercellular cementing substances in five epitheliomas.* The antimetastatic influence of Hale-positive material was again fully evident in epitheliomas (Table 1, 9–13). On the other hand, metastatic capacity was the more pronounced the greater the quantity of periodic acid–Schiff (compare Table 1, 9 with 10–13). A moderate amount of a similar

substance could also be seen in the stroma of the more invasive epitheliomas (not mentioned in Table 1), a phenomenon already described by Gersh and Catchpole[2].

(3) *Intracytoplasmic Hale- and periodic acid–Schiff-positive material.* Hale-positive material was in general present in the cells of slightly and non-metastasizing tumours (Table 1, 1, 2, 9 and 12′); it was absent or less abundant in the cells of other metastatic tumours (exception Table 1, 10 and 11). The intracytoplasmic periodic acid–Schiff was observed in diffuse form in all cells, and as granules in some. The granules were apparently absent in tumours 2, 9, 10 and 11.

Cytoplasmic Hale-positive material frequently occupied a concavity of the nucleus (Golgi zone). This is probably the site of synthesis of Hale-positive material, especially in the ascitic form of *Pch* (Table 1, 12′). The concentration of mitochondria around this region is in favour of this assumption, as likewise various morphological signs of metabolic activity of the nucleus: digitations of its membrane and a greater concentration of the chromatin adjacent to the Golgi zone.

In several tumours (Table 1, 1, 2, 9, 10, 11 and 12′) cytoplasmic Hale-positive material seemed to be continuous with that present in the intercellular spaces. A similar continuity of periodic acid–Schiff material was observed only occasionally and irregularly.

Certain observations suggest that the cementing substances are synthesized and secreted rather than absorbed by the tumour cells. This assumption is supported by the extension of the cytoplasmic Hale-positive material from the nuclear indentation to the cell wall, and finally to intercellular spaces, as observed in our tumour 12′ growing intraperitoneally. This may possibly explain why tumours differ as to local invasiveness and metastatic behaviour, both depending seemingly on the quantity and nature of the cementing substances originating in the tumour cells themselves.

This work was supported by grants from the Damon Runyon Memorial Fund (*DRG*-403 *B*) and the Rockefeller Foundation (*RF* 56150).

Relation of Leydig Cells in the Human Testicle to the Tubules and Testicular Function

GROUPS of Leydig cells have been found in the spermatic cords in 23 of 30 consecutive necropsies. The groups of Leydig cells most commonly occur in the 3 cm. of cord immediately above the upper pole of the testes, but they may be found up to 10 cm. above the globus major, with considerable variation in distribution, both in numbers present and numbers of levels. The cells are constantly distributed in the loose areolar tissue around nerve sheaths and usually infiltrate the nerve bundle, disorganizing the characteristic wavy pattern of nerve fibres. Such cells show all the morphological features characteristic of Leydig cells, crystalloids of Reinke and hyaline bodies occasionally being evident. Infiltration of the nerves by Leydig cells has been described, but not explained, by various authors[1-4]. Some thirty years ago this peculiar association occasioned discussion as to the nature of the cells[5,6]. The relation to nerves can be accounted for either (*a*) by migration along nerve fibres at the embryonic period when nerve fibres grow into testicular parenchyma, or (*b*) by traction of cells from the formed parenchyma during descent of the testicle. The first explanation can be discounted by the similarity of the trabecular pattern of capillaries in normal nerves and the trabecular pattern shown by the infiltrative cells before their continued proliferation disrupts the organized appearance of the nerve.

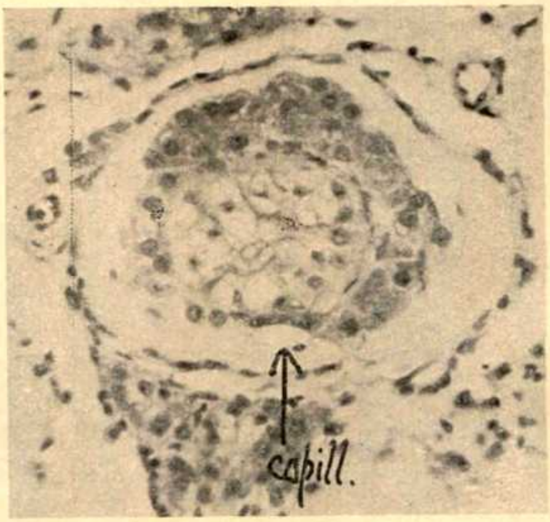

Fig. 1. Hyaline thickening of tubule with residual germinal epithelium and intact inner lamella surrounded by Leydig cells, and with empty capillary spaces at 6 o'clock. (Hæmatoxylin and eosin. × 250)

A similar infiltrative proliferation is seen in hyaline change of the tubular substantia propria where histological detail is clearer, and where active changes take place at the inner lamella, to which are applied thin-walled capillaries. In ordinary paraffin preparations such capillaries are one cell thick and similar to those inside nerve bundles. From the earliest phases of hyaline thickening of the tubule wall, varying numbers of Leydig cells have been seen within the substantia often continuous with groups outside the tubule. In advanced thickening, Leydig cells are typically applied to the inner lamella (Fig. 1). Leydig cells are generally regarded as being an endocrine epithelium and intimate application to thin-walled capillaries is to be anticipated. This association in sites that are abnormal by conventional anatomical standards may be of general biological significance.

In the testes, the intertubular tissue is of scant cellularity, with most of the capillaries present, either in Leydig cell groups or closely applied to the tubule wall. Thus, there are few available capillaries of optimum size along which Leydig cells may proliferate, and the immediate explanation of this infiltrative activity probably is that the capillaries of the invaded structures are the only ones available. This raises the questions (*a*) why, in Leydig cell proliferation, adequate numbers of new capillaries are not formed, and (*b*) what factors limit growth along the existing vascular tree.

In (*a*) a recent preliminary report[7] on the possible reduction in the number of small blood vessels in the seminal vessels of the castrate rat is in part suggestive that the local action of Leydig cell secretion may effect capillary proliferation. However, the process of infiltration of the hyaline substantia is usually diffusely distributed. In (*b*) if it is assumed that endocrine epithelium must have a thin-walled capillary blood supply, it follows that limitation of proliferation along the capillary bed, away from the tubular capillaries, will be effected by increasing thickness of the vessel wall, be it arteriole or venule. The point of importance in these observations is that the same capillary supplies Leydig cells and tubule.

Because of the extreme tortuosity of the tubules and the close application of many of the Leydig cells to the tubular wall, it is difficult to demonstrate clearly on which side of the tubular capillary bed the Leydig cells are situated. In the spermatic cord the Leydig cells are situated close to the arterioles and the same relations probably exist within the testicular parenchyma.

On the basis of these findings, I advance the hypothesis that Leydig cells are situated between the arterioles and the testicular tubules and have the same capillary blood supply as the tubules. This hypothesis may usefully be applied to several aspects of testicular function, notably the gonadotrophic effect of steroid hormones and their varying effect at different dosage-levels, the irregular segmental distribution of atrophic changes in mature testes, pubertal development and abnormal segmental development as in cryptorchidism, as well as possible mechanisms in male infertility and its therapy.

HISTOLOGY

Histochemical Demonstration of Succinic Dehydrogenase Activity in Osteoclasts

A REVIEW of the literature has revealed but few studies on enzyme characteristics of osteoclasts. None of these, however, related to dehydrogenase activity.

In the present work frozen sections of rat and hamster knee joints and jaws, 8–10μ thick, were prepared according to the Adamstone–Taylor cold knife technique and mounted on glass microscope slides. In addition, pieces of calvarium from new-born hamsters were also employed. Slides and specimens were then incubated for 60–90 min. in the succinic dehydrogenase substrate solution as described by Pearson[1]. This contained nitroneotetrazolium. Representative sections were also incubated in a substrate solution containing nitro blue tetrazolium[2] as described by Nachlas *et al.* With both substrates an intense selective staining reaction was observed in osteoclasts (Fig. 1). Sections incubated in tetrazole without the co-factor (succinate) were unstained, as were heat-treated sections. Sodium malonate was inhibitory. The staining of osteoclasts associated with the remodelling resorption of the jaws was particularly striking. Osteoblasts by contrast showed little if any reaction.

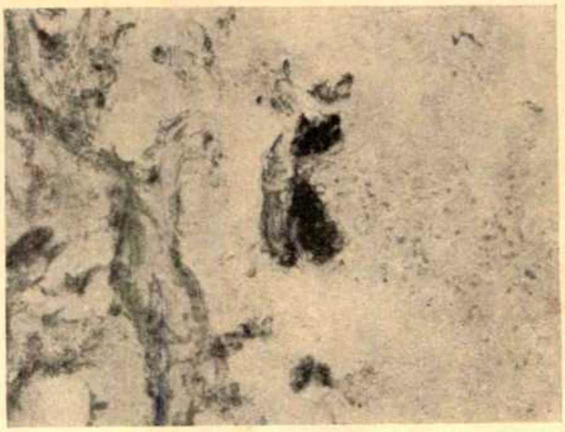

Fig. 1. Succinic dehydrogenase activity of osteoclasts (knee joint from 2-day-old hamster). (× *c*. 214)

Osteoclasts associated with both intramembranous and intracartilagenous bone resorption showed a similar reaction. The cytoplasm was evenly stained, and it was difficult to assess any mitochondrial reaction.

Osteoclasts have also been observed to exhibit high acid phosphatase[3] and aminopeptidase activity[4]. The present study would further tend to confirm the hypothesis that these cells exhibit high metabolic activity. Localization of succinic dehydrogenase to osteoclasts may be considered as presumptive evidence that the Krebs cycle is involved in the resorptive process.

Histochemical Localization of Oxidase Activity in the Mitochondria of the Heart in Some Lower Vertebrates

WITH the aid of some new methods[1-3] the histochemical localization of oxidase activity was investigated in the mitochondria of the heart in some lower vertebrates, namely, the viviparous cyprinodonts, *Lebistes reticulatus*, *Xiphophorus helleri* and *Xiphophorus maculatus*, the carp, *Cyprinus carpio*, the frog, *Rana temporaria*, the toad, *Bufo calamita* and the lizard, *Lacerta agilis*.

To permit a satisfactory comparison with the results of Burstone[3] obtained with the mitochondria of the human heart, we applied the corresponding histological technique. Immediately after death by decapitation, 8-μ thick sections of frozen heart muscle were prepared according to the cold-knife method of Adamstone–Taylor, after which they were mounted on chemically clean glass microscope slides. The incubation, which was carried out at 24° C. and lasted ½ hr., was in a substrate solution containing 10 mgm. of variamine blue *B* base or *p*-methoxy-N-phenyl-*p*-phenylenediamine (Carbic Color and Chemical Co., New York) and 10 mgm. of *p*-aminodiphenylamine or N-phenyl-*p*-phenylenediamine (British Drug Houses, Poole, England). At first the substrates were placed in a 50·0-ml. Erlenmeyer flask and dissolved in 0·5 ml. of ethanol reagent. After adding 35·0 ml. of distilled water and 15·0 ml. of 0·2 *M tris* buffer *p*H 7·4 the solution was shaken and filtered through folded filter paper into a Coplin jar. Incubating solutions containing 0·001 *M* sodium sulphide as well as 0·001 *M* potassium cyanide were also used. In addition, the effect of adding per Coplin jar 20·0 mgm. of cytochrome *c* (Sigma Chemical Co., St. Louis, Mo.) to the substrate solution was studied. Some sections were pretreated with physiological saline for half an hour prior to the incubation. Afterwards the sections were incubated in substrate solutions with and without cytochrome *c*. After incubation the slides were stored for 1 hr. in a 10 per cent solution of cobaltous acetate in 10 per cent formalin containing 5·0 ml. 0·2 *M p*H 5·2 acetate buffer. Then the slides were washed for about 5 min. in running water and mounted in polyvinyl pyrrolidone[4] or glycerol-gelatin.

The distribution of the dye with routine incubations appeared to correspond to that found with the classical mitochondrial stains such as the Regaud stain. Just as in the human heart[3] the localization corresponded exactly to those observed for heart sarcomes or mitochondria by Cleland and Slater[5] when using the mitochondrial method of Altmann. Also in our cases the distribution of the staining corresponded very well with the sarcoma pattern as observed under the electron microscope[6]. Some areas showed a perinuclear staining corresponding to the localization of the perinuclear sarcomes.

When the reaction was completely inhibited by addition of sulphide and cyanide, as effected by pre-incubation in physiological saline, it was completely restored in the saline-treated sections by addition of cytochrome *c* to the substrate solution. Moreover, the staining intensity could be augmented to some degree by adding cytochrome *c* to the routine incubation solutions. Consequently, the cytochrome oxidase is believed to be associated with the mitochondria. Just as in the human heart[3], on the strength of the localization of the staining reaction to the mitochondria, the results of the sulphide and cyanide inhibition and the cytochrome *c* tests, one can conclude that cytochrome oxidase occurs in the heart of the lower vertebrates investigated.

ENTOMOLOGY

Nocturnal Detection of Tsetse Flies in Nigeria with Ultra-Violet Light

Jewell[1,2], in Tanganyika, showed that tsetse flies marked with fluorescent paint can be located at night by means of ultra-violet light resting on leaves. A portable petrol generator was his current supply (personal communication). Because such equipment is cumbersome, other workers[3] have used a hand torch to search for flies painted with reflective glass beads mixed with glue.

The ultra-violet method has been used at the West African Institute for Trypanosomiasis Research to study the nocturnal resting sites of *Glossina palpalis* R.-D. and *G. submorsitans* Newst. in Northern Nigeria. A portable, fairly compact, battery-powered current supply is used. In the case of *G. palpalis*, the information so obtained will form the basis of an experiment on the selective spraying of residual insecticide during the dry season.

The apparatus was supplied by Electric and Musical Industries, Limited, Hayes, Middlesex. A 12-V. car battery feeds d.c. current to a 'Valradio 12/150*B*' convertor which produces a.c. current at 250 volts. After passing through special control gear and the necessary chokes and condensers, this voltage powers two 80-watt ultra-violet bulbs, each in a parabolic reflector on 100 ft. of flex. The entire machine, in a wooden case, fits into a car boot. If no road exists to the study area, the equipment can be broken into two 50-lb. loads, one of which is the battery. These are easily head-carried by labourers. The pigment, a non-radioactive, luminescent powder, was supplied by Barber Medico-electronic Laboratories, Ltd., Weston-super-Mare, Somerset. It adheres well to the thorax of the fly if mixed with thin gum arabic office glue to which has been added a trace of detergent. In the laboratory, painted flies survive as well as unpainted controls. Four colours (blue, yellow, white, orange) are used, permitting sex, time of marking and hunger stage to be identified if desired.

The quantity of light varies with individual bulbs, the best of which concentrate a central beam of ultra-violet sufficient for detecting flies at a distance of 25–30 ft. Sufficient light in the visual range is produced to enable the operator to move about without a torch. The light is attractive to flies disturbed by the operator's movements, and some will fly into the reflector. These can be shaken out and if the lamp is directed away from them, will come to rest nearby. Undisturbed flies, however, do not leave their perches to come to the light, nor does closer inspection with a hand torch disturb them. Some confusion is caused by fireflies (Lampyridae), but these can be identified by their regular flashing. Certain arachnids and fungi fluoresce under ultra-violet, but never as brightly as the painted flies.

Many trials with the riverine species, *G. palpalis*, have revealed that about half the flies rest during the night within 12 in. of the ground, on leaves or small twigs, but never on tree trunks or branches. There appears to be no difference between the sexes in resting height preference at night. Flies released in the morning are rarely found on the night of the same day, having dispersed up- and down-stream in search of food. The best method is to catch the flies in the afternoon, then mark and drop them into a large cage with a removable top. At dusk the cage top is removed, and those flies that fly out are considered uninjured by handling and marking. 10–25 per cent of marked *G. palpalis* come to rest within the 125-ft. searching radius of the machine, the great majority of them alighting very close to the point of release.

Approximately 50 recoveries of marked specimens of the open woodland species, *G. submorsitans*, in a forest-island breeding site, revealed the flies resting on twigs, leaves and small creepers at heights ranging from 1 to 15 ft., with the majority above 7 ft. It would appear, then, that this species' daytime resting preference for tree trunks, at least when gorged[4], should be considered when planning control by residual insecticides.

Both species' habit of resting on leaves and twigs at night might be a means of avoiding predators such as ants and jumping spiders, the vibration of the predator's approach serving to alert the fly, whereas a branch or tree trunk daytime habitat would permit maximum visibility in the fly's search for a host.

Sex-limited DDT-Resistance in House-flies

A NEW mechanism of inheritance of DDT-resistance has been investigated in a selected strain of house-flies (*Musca domestica* L.) wherein resistance is manifest only in males. Genetic tests have shown that the resistance is transmitted by males but not by females. It is therefore determined either directly by a *Y*-chromosome factor or, like sex in *Drosophila*, by the balance between the unpaired parts of *X* and *Y* and the rest of the chromosome set.

Evidence for the existence of this patrilineal inheritance dates back to 1954 when an attempt was first made to derive a homogeneous susceptible strain from the Canberra laboratory colony[1] which, although bred since 1939 in isolation from insecticides, had been found to contain a DDT-resistance factor in a small proportion of both males and females. Selection for early maturation (giving strain *E*) eliminated resistant females by the sixth generation, but the strain continued to produce some resistant males which, during a further 68 generations, increased in proportion to about 75 per cent of males produced.

At this stage a complete separation of resistant and susceptible males was effected in a single selection by breeding, on one hand, from males which survived a topically applied dose of 32·0 μgm. DDT/gm. body-weight, and, on the other hand, from males which when tested later were killed by a dose of 11·2 μgm. DDT/gm. The two strains so obtained were designated *EY* (early, with resistance involving *Y*) and *ES* (early, susceptible).

Males and females of *ES* and females of *EY* constitute three similar and apparently homogeneous populations in respect to their tolerances to DDT, which lie between 2·0 and 11·2 μgm./gm. *EY* males are consistently about eight times as resistant, their tolerances ranging from 16·0 to 128·0 μgm./gm.

Strain *EY* has bred true without any applied pressure since the initial selection. All its males are specifically DDT-resistant and all its females non-resistant. It contrasts markedly with previously described strains of houseflies, for in these resistance to DDT has been found to be autosomally determined and not sex-linked or sex-limited[2-4]. A fuller account of this work will be published elsewhere.

BACTERIOLOGY

Intermediary Metabolism of Nitrobenzoic Acids by Bacteria

KE *et al.*[1] have recently reported that the aerobic degradation of *o*-nitrobenzoic acid by a *Flavobacterium* involves the *o*-nitroso and *o*-hydroxylamino compounds. The corresponding amino-derivative, anthranilic acid, was not oxidized, their paper implying on the basis solely of manometric data that it was not a potential metabolite of *o*-nitrobenzoic acid although they found that cells grown on anthranilic acid could oxidize both it and salicylic acid. We wish to direct attention to the fact that although the aminobenzoates may not always be directly concerned in aerobic degradation of nitrobenzoic acids, they are nevertheless important intermediary metabolites.

We had previously recorded identical responses to those reported by Ke *et al.*, with *p*-nitrobenzoic acid and its derivatives, using cells of *Nocardia erythropolis* grown in the presence of *p*-nitrobenzoic acid, and with *o*-nitrobenzoic acid using cells of *N. opaca*, grown in a medium containing *o*-nitrobenzoic acid[2]. Although the aminobenzoic acid in both cases was not appreciably oxidized, it nevertheless accumulated in culture media. Work with cell-free extracts has shown that in addition to oxidation of the substrate, *N. erythropolis*, at least, carries out an appreciable, simultaneous reduction of the *para*-isomer to *p*-aminobenzoic acid by a pathway involving *p*-nitrosobenzoic and *p*-hydroxylaminobenzoic acids[3].

In contrast to Durham's earlier work[4,5] and the recent report of Ke *et al* [1], no further oxidation of the aminobenzoates through the corresponding hydroxybenzoates has been found with our species of *Nocardia*. Cells of *N. opaca* grown on anthranilic acid failed to oxidize salicylate and growth of *N. erythropolis* was not maintained on *p*-aminobenzoic acid[6]. The use of desiccator-dried preparations of *N. opaca* showed that permeability factors were not responsible for absence of activity in that particular case.

The scheme of Ke *et al.*[1] whereby *o*-hydroxylaminobenzoic acid is metabolized to cellular material without passing through anthranilic acid is interesting in view of some results we obtained with *N. erythropolis*, which oxidizes *p*-nitrobenzoic acid through *p*-hydroxybenzoic acid to protocatechuic acid, also without the mediation of the amino-compound.

Table 1. PRODUCTION OF PROTOCATECHUIC ACID FROM *p*-NITROBENZOIC ACID AND ITS REDUCTION PRODUCTS BY *N. erythropolis*

Substrate	Protocatechuic acid produced		
	Exp. 1*	Exp. 2*	Exp. 3*
p-Nitrobenzoic acid	++++	++++	+++
p-Nitrosobenzoic acid	±	±	–
p-Hydroxylaminobenzoic acid	+++	+++	+
p-Aminobenzoic acid	–	–	–
None	–	–	–

–, ±, +, ++, etc., Intensity of protocatechuic acid spots estimated visually.

* Identical sheets were marked in the areas corresponding to protocatechuic acid, the areas cut out, eluted and a full spectrum read (210–320 mμ).

Experiment 1 was made with 24-hr. grown cells; experiment 2 with 48-hr. grown cells and experiment 3 with cells grown for 7 days, on *p*-nitrobenzoate.

Washed cell suspensions of *N. erythropolis* (grown on *p*-nitrobenzoate medium) in *tris* buffer with low aeration rates (see Cartwright and Cain[2] for full experimental details of this and all other methods used) produced appreciable amounts of protocatechuic acid from both *p*-nitro and *p*-hydroxylaminobenzoic acids, but much smaller amounts from *p*-nitrosobenzoic acid and none from the amino-compound. It was detected chromatographically in three solvent systems, identified spectrophotometrically (Table 1) and also isolated in pure form from a *p*-nitrobenzoate incubation mixture. The *p*-hydroxylaminobenzoic acid sample used was recrystallized several times from water prior to use and was shown to be quite free of nitro-compound by paper chromatography.

The results would suggest a pathway from *p*-hydroxylaminobenzoic acid to protocatechuic acid and terminal oxidation products lacking an intermediate amino-stage and support the results of Ke *et al.* with the *ortho*-isomer. Although *p*-nitro, *p*-nitroso and *p*-hydroxylaminobenzoic acids were oxidized at similar rates by cells grown on *p*-nitrobenzoic acid, the effects of inhibitors (particularly 1 m*M* nitrite) and other findings[2] still lead us to maintain that, with *Nocardia*, nitrite is the immediate nitrogenous product and that rapid reduction to ammonia is achieved by nitrite reductase activity. This reflects, as Ke *et al.*[1] have pointed out, the great diversity of pathways by which different micro-organisms may degrade the same substrate, but we must advocate the necessity for carrying out concomitant chemical studies with adaptation results of this kind. Our own results have shown that although *p*-aminobenzoic acid is not a direct intermediate in the primary aerobic, energy-producing pathway of *p*-nitrobenzoic acid degradation, it is eventually metabolized both in *p*-nitrobenzoate cultures and after incubation with washed cells of *N. erythropolis* grown on *p*-nitrobenzoate[3]. We have since identified further aminophenyl compounds produced in cultures from *p*-nitrobenzoate and from *o*-nitrobenzoate together with the corresponding hydroxynitrobenzoic acids (Table 2) and detected at least six other unidentified phenolic compounds from the former, none of which is oxidized by the organisms. Recent work (which will be reported in full elsewhere) on anthranilic acid metabolism by *N. opaca* confirms the multiplicity of compounds to which this aminobenzoate may be converted in cultures. This, we think, serves to emphasize the imprudence of eliminating a compound as a major metabolite merely from adaptation results based on manometric studies. If not involved in aerobic pathways, it may well be important in others.

Table 2. SOME AMINOPHENYL AND RELATED METABOLITES PRODUCED BY *Nocardia* SPP. FROM NITROBENZOIC ACIDS

Substrate	Species	Metabolites identified	First appears in cultures (days)
p-Nitrobenzoic acid	*Nocardia erythropolis*	*p*-aminobenzoic acid	1
		3-hydroxy-4-nitrobenzoic acid	3
		3-hydroxy-4-aminobenzoic acid	3
o-Nitrobenzoic acid	*N. opaca*	3-hydroxy-2-nitrobenzoic acid	3
		3-hydroxyanthranilic acid	3
		anthranilic acid	½
		o-aminophenol	3–4

These metabolites were found both in cultures of the two species and in incubation mixtures of washed cells of the respective species in 0·05 *M tris* or phosphate buffer, *p*H 7·2, with *p*- or *o*-nitrobenzoic acid at 0·01 *M*. Incubation temperature in both cases was 30°.

Intrastrain Transduction in *Proteus mirabilis*

A NUMBER of bacteriophage-mediated transduction systems have been described[1]. Intrastrain transduction was originally described for *Salmonella typhimurium* by Zinder and Lederberg[2] and recently Loutit has described a similar situation in *Pseudomonas aeruginosa*[3].

In an attempt to discover transducing systems in the genus *Proteus* for use in genetic transfer between *vulgaris* and *mirabilis* species, lysogeny in this genus was investigated[4]. Two of the temperate phages isolated[5] have been successfully employed in intrastrain transductions. The first was present in the supernatant of 10-day-old cultures of *Proteus mirabilis* strain 34[6] and formed turbid plaques on *Proteus mirabilis* strain 13; it is named phage 34/13. Phage 12/57 was obtained after ultra-violet irradiation[5] of *Proteus mirabilis* strain 12; it forms turbid plaques on *Proteus mirabilis* strain 57. The two transducing systems are analogous and as results are very similar only the one employing phage 12/57 will be described.

Streptomycin-resistant mutants (57/*S*) of the wild type 57 were obtained by plating about 10^{11} cells on a MacConkey-type agar[7] containing 1,000 μgm. streptomycin sulphate/ml. Colonies which arose were picked off and purified by re-streaking on a streptomycin medium.

Phage 12/57 does not produce clearing of broth cultures of 57 or 57/*S*, and in order to obtain high-titre lysates, recourse was taken to the modification of the confluent plaque method of Hershey *et al.*[8] described by Adams[9]. Successful experiments produced lysates of 57 or 57/*S* with plaque titres of 10^{10}/ml. as estimated by the agar layer method[10]. Lysates were centrifuged to clarity and rendered bacteriologically sterile by addition of chloroform.

Transduction experiments were conducted in a 37° C. water-bath and consisted of mixing 2 ml. of a 57/*S* lysate (about 2×10^{10} plaque-forming particles) with a deposit of about 6×10^{8} wild type 57 cells obtained by centrifuging 1 ml. of an aerated overnight culture. The experiments were duplicated using a lysate of the wild type 57 of identical titre. No visible clearing occurs, and 15 min. after mixing, 0·1 ml. volumes were spread on a number of Difco *SS* agar plates. At 30-min. intervals 0·1 ml. volumes were spread on MacConkey agar containing 1,000 μgm. streptomycin sulphate/ml. After overnight incubation the *SS* plates were replicated[11] on to MacConkey agar containing 1,000 μgm. streptomycin sulphate/ml. An organism control (6×10^{8} wild-type 57 in 2 ml. broth) and a lysate sterility control (2 ml. of the lysate) were similarly treated.

Replica plates of the *SS* agar in experiments using lysate from 57/*S* usually yielded about 100 colonies per plate, while those in experiments using the lysate from wild 57 were always sterile. Replica plates from organism controls were usually barren but occasionally showed 1 or 2 colonies per experiment. Lysate controls invariably confirmed their bacteriological sterility.

In experiments using lysates from 57/*S* the half-hourly direct platings on MacConkey agar containing 1,000 μgm. streptomycin sulphate/ml. first yielded colonies 2 hr. after mixing organisms and lysate. The corresponding plates in experiments using lysates of wild 57, and in the organism and lysate controls, never showed growth.

The transducing activity of 57/*S* lysates is not impaired by treatment with deoxyribonuclease (40 μgm. per ml. for 2 hr. at 37° C.) but is totally inhibited by phage 12/57 rabbit antiserum, which reduces the plaque titre from 10^{10} to 10^{4}/ml. The addition of a similar volume of normal rabbit serum to the lysate has no such effect.

Results outlined place this experiment in the class of bacteriophage-transmitted intrastrain genetic exchange.

The streptomycin resistance marker has been the only one employed to date. The high mutation-rate of wild 57 and wild 13 to sodium azide resistance precludes the use of this property as a marker. No biochemical or nutritional mutants have yet been recovered.

The transduction frequency per phage particle is about 10^{-7}, and is comparable with rates encountered in common transduction systems[12]. There appears to be a delay in phenotypic expression of transduced streptomycin resistance. This delay has also been encountered with the transduction of streptomycin resistance in the *Salmonella typhimurium* system[13]. As in the latter system no abortive transductions have been detected.

Study of the transduced organisms has proved that the streptomycin resistance is a stable characteristic. These organisms do not differ biochemically from the wild type. None of the colonies tested to date adsorbs phage present in either 57 or 57/*S* lysates. Mutants of wild 57 resistant to phage present in lysates of 57 are not resistant to streptomycin. The mechanism by which the streptomycin-resistant transductants of 57 become resistant to phage is being investigated.

This work was aided by grants from the South African Council of Scientific and Industrial Research.

Characteristics of *Thiobacillus thioparus*

DURING investigations of the bacterial decomposition of thiosulphate and thiocyanate in effluents from gasworks, it became necessary to identify the organisms responsible. These were *Thiobacilli*, and one in particular, organism *G*, appeared identical with *T. thioparus* as described in Bergey[1]. To confirm this, its behaviour was compared with various *Thiobacilli* from the National Collection of Industrial Bacteria. As a result of this comparison it was discovered that the type species, *T. thioparus* (NCIB 8370), did not correspond with Bergey's classification on two important points: it grew on nutrient agar, and it grew anaerobically on thiosulphate containing potassium nitrate. To check this a further specimen of the organism was obtained, and although this was again a pure culture it showed precisely the same characteristics.

After discussion with a member of the staff of the National Chemical Laboratory, it was concluded that due to difficulties associated with the culture originally given to the Collection, NCIB 8370 was probably not *T. thioparus*.

The matter is of some importance, as strain NCIB 8370 was used by De Kruyff *et al.*[2] to show that *T. thioparus* and *T. thiocyanoxidans* are identical; as it seems not to be *T. thioparus* their conclusions would appear to be invalid.

We wish to thank the Joint Research Committee of the Gas Council and the University of Leeds for permission to publish this communication.

FORTHCOMING EVENTS

(*Meeting marked with an asterisk * is open to the public*)

Monday, March 21

Society of Chemical Industry, Pesticides Group (at 14 Belgrave Square, London, S.W.1), at 5.30 p.m.—Dr. E. K. Woodford and Mr. L. Kasasian: "Some New Herbicides and Developments in Chemical Weed Control 1958–60".

Manchester Literary and Philosophical Society (in the Reynolds Hall, Manchester College of Science and Technology, Sackville Street, Manchester), at 5.45 p.m.—Mr. C. E. Young: "The Growing Importance of Metallo-Organic Compounds" (Presidential Address).

Institution of Mechanical Engineers, Industrial Administration and Engineering Production Group (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Informal Discussion on "The Computer in Production".

Institution of Electrical Engineers, London Graduate and Student Section (at Savoy Place, London, W.C 2), at 6.30 p.m.—Dr. F. A. Benson: "Developments in Lighting".

Royal Geographical Society (at 1 Kensington Gore, London, S.W.7), at 8.30 p.m.—Mr. Martin W. Holdgate: "Islands of Western Patagonia".

Tuesday, March 22

British Museum (Natural History) (in the Lecture Hall, Cromwell Road, London, S.W.7), at 4.30 p.m.—Prof. Charles G. Sibley (Cornell University): "Genes, Proteins and Evolution—The Phylogeny of Birds as indicated by Molecular Structure".*

Institute of Physics, Electronics Group (at 47 Belgrave Square, London, S W.1), at 5.30 p.m.—Annual General Meeting, followed by Mr. P. O. Hawkins: "Neutron Sources".

Institution of Chemical Engineers (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. R. L. Brown and Mr. J. C. Richardson. "Profile of Flow of Granules Through Apertures".

Tuesday, March 22—Thursday, March 24

Royal Institution of Naval Architects (in the Weir Lecture Hall, 10 Upper Belgrave Street, London, S.W.1), at 10.15 a.m. daily —Spring Meeting.

Wednesday, March 23

Institute of Fuel (at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 5 30 p.m.—Mr. H. R. Gregory: "A New Method of Briquetting Coal without a Binder".

Institution of Electrical Engineers, Electronics and Communications Section (at Savoy Place, London, W.C.2), at 5.30 p.m. —Mr. G. Millington: "The Challenge of the Propagation Medium to the Radio Engineer".

Royal Photographic Society, Scientific and Technical Group (joint meeting with the Colour Group of the Physical Society, in the Lecture Theatre of the Science Museum, South Kensington, London, S.W.7), at 5.30 p.m.—Mr. M. H. Wilson: "Two-colour Projection Phenomena".

Society of Chemical Industry, Food Group (at the Courtauld Hall, Queen Elizabeth College, Campden Hill Road, London, W.8), at 6 p.m.—Scientific Papers (Eighth Young Members' Meeting).

British Psychological Society, Medical and Social Psychology Sections (at the Royal Society of Medicine, 1 Wimpole Street, London, W.1), at 8.30 p.m.—Dr. R. Money-Kyrle and Dr. Marie Jahoda: "Prejudice".

Thursday, March 24

Royal Society (at Burlington House, Piccadilly, London, W 1), at 4.15 p.m.—Meeting for the Election of Fellows. Mr. A. G. Swallow and Miss Mary R. Truter: "The Stereochemistry of β-Diketo Complexes with Trimethylplatinum IV. I: The Crystal Structure of Trimethyl 4 : 6-Dioxononylplatinum"; Mr. A. C. Hazell and Miss Mary R. Truter: "The Stereochemistry of β-Diketo Complexes with Trimethylplatinum IV. II: The Crystal Structure of Ethyl (Trimethylplatini-)acetoacetate".

Institution of Mechanical Engineers, Applied Mechanics Group (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m. —Discussion on "A Replica Technique for Measuring Static Strains".

Royal Aeronautical Society (at the Institution of Mechanical Engineers, 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m. —Dr. R. R. Jamison and Mr. R. J. Lane: "Engines for Supersonic Air Liners".

Thursday, March 24—Friday, March 25

National Association for Mental Health (at Church House, Westminster, London, S.W.1)—Annual Conference—"Mental Health at Home and Abroad".

Friday, March 25

Royal Aeronautical Society (at 4 Hamilton Place, London, W.1), at 7 p.m.—Mr. D. Perkins: "Aerodynamics of Man Powered Flight, with special reference to Inflatable Wings".

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Prof. Ronald King: "Tyndall, The Teacher".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Cowburn Research Fellow, to undertake research on certain aspects of immunology in relation to cancer—The Secretary, King's College Hospital Medical School, Denmark Hill, London, S.E.5 (April 2).

Assistant Experimental Officer (with a science degree preferably including bacteriology and chemistry, and some experience in bacteriological work) in the Bacteriology Department—The Secretary, Hannah Dairy Research Institute, Kirkhill, Ayr (April 4).

Assistant Lecturer in Physiology or Pharmacology—The Registrar, The University, Nottingham (April 4).

Senior Lecturer in Applied Thermodynamics; a Senior Lecturer in Fluid Mechanics; a Senior Lecturer in Mechanics of Machines; a Senior Lecturer in Strengths of Materials; a Senior Lecturer in Production Technology; and a Lecturer in Mechanical Engineering—The Registrar, Royal Technical College, Salford 5, Lancs (April 4).

Assistant (preferably with special interests in the biochemistry or micro-organisms, or in physical biochemistry) in Biochemistry —The Secretary of University Court, The University, Glasgow (April 8).

Assistant (with a degree in agriculture, horticulture or economics) to the Horticultural Liaison Officer in the Department of Agricultural Economics—The Registrar, The University, Nottingham (April 9).

Assistant Lecturer (preferably with a knowledge of some branch of comparative physiology, especially neurophysiology) in the Department of Zoology—The Registrar, University College of Wales, Aberystwyth (April 9).

Lecturer (with a good honours degree in electrical engineering or the equivalent, and ability to participate effectively in research work in this field) in the Department of Electrical Engineering, with special reference to the transmission and distribution of electric power—Prof. A. Tustin, Department of Electrical Engineering, Imperial College of Science and Technology, London, S W.7 (April 9).

Senior Lecturer in Virology, to be responsible for the organization of virology and for teaching in the Department of Pathology —The Secretary, Medical College of St. Bartholomew's Hospital, West Smithfield, London, E.C.1 (April 9).

Lecturer in Agricultural Chemistry—The Secretary of University Court, The University, Glasgow (April 11).

Lecturer in Astronomy in St. Salvator's College—Joint Clerk to the University Court, College Gate, St. Andrews, Fife (April 16).

University Lecturers (2) (one with special reference to mycology and plant pathology and the other to ecology) in Botany—Dr. C. B. Goodhart, Museum of Zoology, The University, Downing Street, Cambridge (April 18).

Cancer Research Fellow (with training in cytology), for duties mainly in connexion with the study of human chromosomes in patients with leukæmia and associated diseases—The Registrar, The University, Liverpool, quoting Ref CV/N (April 19).

Chair of Zoology in the University College of Ghana—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (April 20).

Senior Lecturer or Lecturer in Anatomy; and a Senior Lecturer or Lecturer in Physiology at the University of Khartoum—The Registrar, University of Khartoum, c/o Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (April 20).

Lecturer/Senior Lecturer (with either travel or field experience in Greece and Italy or the Near East) in Classical or Near Eastern Archæology, at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, April 22).

Assistant Lecturer (with special qualifications in physical chemistry) in Chemistry—The Secretary, The Royal College of Science and Technology, George Street, Glasgow, C.1 (April 23)

Assistant Lecturer or Lecturer (preferably with a special interest in some group of fossils common to the lower Palæozoic rocks) in Palæontology—The Registrar, University College of Wales, Aberystwyth (April 25)

Imperial Chemical Industries Research Fellows in Biochemistry, Chemistry, Chemotherapy, Engineering, Metallurgy, Pharmacology or Physics—The Academic Registrar, University of London, Senate House, London, W.C.1 (April 30).

Lecturer (graduate in science) in Microbiology—The Secretary, The Queen's University, Belfast (April 30).

Lecturer in Inorganic Chemistry—The Registrar, The University, Manchester 13 (April 30).

Research Assistant (with an honours degree in mathematics or a related subject, and preferably experience in the use of digital computers) in the Computing Laboratory—The Secretary of University Court, The University, Glasgow (April 30).

Senior Lecturer in Physics; and a Lecturer in Physics at the University of Natal, Pietermaritzburg, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (South Africa and London, April 30).

Turner and Newell Research Fellow in Engineering, Inorganic Chemistry or Physics—The Academic Registrar, University of London, Senate House, London, W.C.1 (April 30).

University Students and Fellows, for experimental or theoretical research in nuclear and elementary particle physics—The Professor of Natural Philosophy, The University, Glasgow (April 30).

Chair of Chemistry in the University of Hong Kong—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Hong Kong and London, May 30).

Biochemist (interested in biological assay work) for Endocrinology Laboratory, working in connexion with cancer research—The House Governor, Royal Marsden Hospital, Fulham Road, London, S.W.3.

Biochemist (preferably with previous hospital experience) in the Pathological Laboratory—The Secretary, Highlands General Hospital, Winchmore Hill, London, N.21.

CHEMIST or AGRICULTURAL CHEMIST (with an honours degree in science or equivalent qualification, and preferably postgraduate research experience to Ph.D. level, and a knowledge of agriculture), to undertake research on the quality of protein in animal feeding stuffs for non-ruminants—The Secretary, The Rowett Research Institute, Bucksburn, Aberdeen.

CYTOLOGIST (Scientific or Senior Scientific Officer grade) AT THE WELSH PLANT BREEDING STATION—The Registrar, University College of Wales, Aberystwyth.

DARWIN RESEARCH FELLOW (with suitable qualifications in science or medicine), for research in the field of human population genetics with special reference to the range of human variability—The Eugenics Society, 69 Eccleston Square, London, S.W.1.

EDITOR (chemist, with editorial experience) OF *Chemistry and Industry*—The General Secretary, Society of Chemical Industry, 14 Belgrave Square, London, S.W.1, marking envelope "Personal".

LECTURER (with good academic qualifications and either experience of, or special interest in, nuclear physics) IN PHYSICS, at Bournemouth Municipal College of Technology and Commerce, to help with the development of courses in nuclear and reactor physics and teach physics to Grad.Inst.P., H.N.C. applied physics and B.Sc. (General) levels—Chief Education Officer, Town Hall, Bournemouth.

MASTER TO TEACH CHEMISTRY throughout the School—The Headmaster, Malvern College, Malvern.

MICROBIOLOGIST (with research experience), for work on radiation-induced mutations in microbial populations—The Administrator, Radiobiological Research Unit, Medical Research Council, Harwell, Berks.

PHYSICISTS (with doctorate degree, and preferably a fair knowledge of French)—Le Directeur, Departement de Physique, Université de Montréal, Canada.

RESEARCH ASSISTANT (graduate), to join a group working on problems of cancer research in the border-line fields of biology and chemistry—The Administrative Officer, Mount Vernon Hospital, Northwood, Middlesex.

RESEARCH POST IN THE RADIOASTRONOMY GROUP, to participate in an expanding programme of research in upper atmosphere physics, including investigations of meteors, auroræ and solar-terrestrial relations—Dr. T. R. Kaiser, Department of Physics, The University, Sheffield 10.

TECHNICIAN or JUNIOR TECHNICIAN (interested in biochemistry), for biochemical and biological assay work in the ENDOCRINOLOGY LABORATORY—The House Governor, Royal Marsden Hospital, Fulham Road, London, S.W.3.

IN THE SERVICE OF YOUTH

THE second[*] of two recently published reports concerned with the way in which the State should assist in the service of youth has met with much more sympathetic public response than the first[†]. The Committee was set up by the Minister of Education just over a year ago, under the chairmanship of the Countess of Albemarle, and has completed its inquiry with exemplary promptness. Invited to "review the contribution which the Youth Service of England and Wales can make in assisting young people to play their part in the life of the community, in the light of changing social and industrial conditions and of current trends in other branches of the education service ; and to advise according to what priorities best value can be obtained for the money spent", the Committee quickly realized that it had been convened none too soon and that speedy action would be required if the Youth Service were to flourish. It is not surprising to learn from the Report that the Committee was always aware that it was working against time and that the recommendations made should be regarded as in the nature of a blood transfusion. Side by side with the Committee's proposals for immediate adoption come proposals which would ensure sustained and continued nourishment if the blood transfusion succeeds in restoring the health of a sickly and dispirited child.

The main factor contributing to the sense of urgency which governed the Committee's inquiry is, of course, the 'bulge'. For every five young people between the ages of fifteen and twenty in Britain to-day there will be, in 1964, six young people. Although the increase will not be spread evenly across the country as a whole, all areas and each kind of area will show some increase ; in some new towns the increase may be as much as five-fold. Between 1964 and 1970 the total number will decline gradually, but will still remain substantially higher than that of to-day. From 1970 there is again the probability of a gradual increase. The inadequate facilities which are available in the Youth Service to-day are quantitatively insufficient to meet demands which are already upon us. Measures taken to meet the impact of the 'bulge' in the schools and technical colleges and the universities have not been matched with similar provision to prepare the Youth Service for the needs of the increased population. The Committee quickly recognized that unless action is taken at once the 'bulge' generations will leave school only to find a Youth Service inadequate to cope even with its earlier responsibilities.

The effects of the 'bulge' will be reinforced by the cessation of National Service. During the past few years military commitments have kept about 200,000 young men between the ages of eighteen and twenty out of civilian life. Its gradual abandonment during the next two or three years will leave this number of young men available for civilian employment and leisure pursuits. Despite sincere beliefs that National Service has had a wholly unsatisfactory effect upon the lives and characters of many young men in leading to excessive drinking and sexual promiscuity, it is generally accepted that it has provided the majority of those serving with challenge and adventure suitable to their age and needs. The nation, and the young men themselves, will be the poorer unless the Youth Service can provide, in relevant civilian terms, opportunities to match those which come through National Service. The cessation of National Service and the arrival of the 'bulge' will make the Youth Service responsible for about a million more young people in 1964 than it had to cater for in 1958.

A third factor which strengthened the Albemarle Committee's belief that the Youth Service needed immediate support is the unfortunate emergence of a new climate of crime and delinquency. Without wishing to exaggerate the incidence of delinquency, which still involves in any one year only about 2 per cent of boys aged fourteen and less than twenty-one and only 0·2 per cent of girls of the same age group, it is still the fact that, of the total number of persons found guilty of indictable offences in 1957, about 50 per cent were less than twenty-one, and 30 per cent were aged 14–20 inclusive. Whether the figures are large or small in relation to the total population, the crime problem is largely a youth problem, and one in which the public can reasonably expect the Youth Service to play a considerable part in its solution.

To meet the challenge of the 'bulge' and the opportunities provided by the cessation of National Service, as well as to serve the nation in helping to combat the incidence of delinquency among young people, demands a Youth Service made up of virile and enthusiastic men and women dedicated to their calling. This was scarcely the position which confronted the members of the Albemarle Committee during their investigations. Instead, the Committee found leadership suffering from shortage of money and lack of encouragement. Leaders, feeling unsupported and unappreciated, have looked for some sign that their work is nationally recognized as important. They find it neither in official expressions of policy nor in the rewards of a salary scale for those who are full-time which would put the work on a level with cognate professions. They seem to themselves to be in danger of becoming cut off from the march of social and educational advance, and it is neither surprising that the total number of full-time youth leaders is declining nor that full-time posts are failing to attract applicants with the desired qualities.

---

[*] Ministry of Education. The Youth Service in England and Wales; Report of the Committee Appointed by the Minister of Education in November, 1958. Pp. iv+136. (Cmnd. 929.) (London: H.M. Stationery Office, 1960.) 6s. net.

[†] Ministry of Education. 15 to 18: A Report of the Central Advisory Council for Education (England). Vol. 1: Report. Pp. xxxi+519. (London: H.M. Stationery Office, 1959.) 12s. 6d. See also *Nature*, February 6, p. 341.

For the running down of the Youth Service and the decline in morale of its leadership, the main responsibility must be pinned on the door of the Ministry of Education. The high hopes raised in 1939 by the issue of Circular 1486 by the Board of Education, which was commended (see *Nature*, 146, 627; 1940) as an imaginative act by the Government, have been dashed by subsequent performance. During the ten years up to the end of 1958, the Ministry has not issued a single circular devoted solely to the Youth Service. During the same period there have been ten circulars having some bearing on the Youth Service and seven of them imposed restrictions. The Select Committee on Estimates, in its Report of July 1957, referred to this discouraging effect and put it down to "lack of interest on the part of the Ministry of Education in the present state of the Service and the apathy about its future"*.

In view of the Ministry discouragements, it is not surprising that many local education authorities have shown quixotic attitudes towards the Youth Service. It may seem incredible, but some so-called progressive authorities have no youth committee and no youth officer. Even authorities which value the Service show surprising variations in their practical approaches to its methods of organization and administration and, as a result, there is no accepted minimum standard of services which voluntary bodies of standing can expect from every authority as a matter of course.

It is, indeed, a tribute to the voluntary organizations—and of the voluntary principle which permeates the Youth Service—that the Youth Service has continued to remain in being at all. Apart from the time and devotion given to the Service by so many voluntary helpers—which may include members of local authorities in their official capacities as well as unpaid representatives of voluntary organizations—the taxpayers and ratepayers are usually surprised to learn that the financial weight of the Youth Service falls mainly upon the voluntary organizations. The Standing Conference of National Voluntary Youth Organizations has stated that it is not unusual for its member organizations to have to raise from private and voluntary sources 90 per cent of its total yearly expenditure on headquarters administration, the provision of regional organizers and the training of leaders. Against this, the total sum spent on the Youth Service from the Ministry of Education and local education authority funds in 1957–58 amounted to the not very grand total of £2¾ million; of every pound spent on education, about 1*d*. went to the Youth Service. Where the Ministry can fairly be charged with dereliction of duty is brought home by the Committee's finding that, during the twelve years up to and including 1957–58, direct expenditure by the Ministry on the Youth Service in terms of real money has fallen by a quarter. It is little wonder that many voluntary workers have lost heart and grown weary of working in the dingy, dilapidated buildings with insufficient equipment which have become the trade mark of so many youth clubs.

Much of the Albemarle Report is rightly given to this analysis of why the Youth Service has failed to march with the times; public opinion should see that, in the national interest, central and local government should not again fail in their duty. To give a clear and unequivocal lead, the Committee makes certain minimum recommendations for immediate action which the Government could ill afford to ignore. Sir David Eccles is to be congratulated for accepting this and for the unparalleled action of asking the House of Commons to accept, in principle, all the recommendations in the Report on the day of its publication.

The main proposal is that the Minister should initiate a ten-year development programme, divided into two stages of five years each. During the first five years advances should be made in each sector of the Youth Service to "catch up with a situation already upon us". During the second five-year period the permanent structure should be securely established. Throughout the period of development, the Minister should have at his disposal the best possible advice and help. The Committee wisely recommends the appointment of a Youth Service Development Council which will be little concerned with administration and far more with inquiry, with the sharing of ideas and the promotion of new activities; on occasions, it may serve to rejuvenate a flagging Minister. This Council has, in fact, now been formed and consists of: the Countess of Albemarle (for a period of one year); Mr. Richard Hoggart, a member of the Albemarle Committee and author of "The Uses of Literacy"; Mr. Christopher Brasher, athlete and journalist; Dr. W. Watson, sociologist from the University of Manchester; Miss M. E. Keatley, Staffordshire head mistress; Mr. Edward Lewis, chairman of Decca; Mr. Timothy Raison, journalist; Miss Ellen McCullough, National Woman Officer of the Transport and General Workers' Union; Councillor Alfred Blake, a member of the Portsmouth City Council; Mr. G. S. Bessey, director of education for Cumberland; Miss P. C. Colson, secretary of the Central Council for Physical Recreation; Mrs. Glyn Roberts, former senior mistress in a secondary modern school in Wales; Mr. Huw Wheldon, broadcaster. The Minister of Education himself will be chairman.

As an immediate step, the Report asks the Minister to put in hand arrangements for training 'professional' youth leaders, both for the emergency and the long term. The full-time youth leader force should be increased from the present total of 700 to a provisional one of 1,300 by 1966. To bring this about, an emergency training college should be opened by the autumn of 1961; Sir David Eccles has already indicated that this will be in Leicester. To anticipate legitimate criticisms about the methods of training youth leaders, a working syllabus has been devised which bears close relationship to those used for training teachers. Much here depends upon the choice of the principal, and it is to be hoped that the over-regimentation found in some of the emergency teachers' training colleges set up after the War may be avoided.

---

* Seventh Report from the Select Committee on Estimates. "The Youth Employment Service and Youth Service Grants." (London: H.M. Stationery Office, 1957.)

Besides recommendations to ensure that salary scales are commensurate with the responsibilities of the job, and that money is spent in providing building and equipment which give young people who leave school at fifteen or sixteen indoor and outdoor facilities at least equal to those enjoyed by the more privileged who remain in full-time education until they reach years of maturity, the Committee makes two recommendations which deserve close attention.

The first is that the Youth Service should be available for all young people aged 14–20 inclusive. However inadvertent, the proposal to lower the statutory age limit from fifteen to fourteen is a striking comment on one of the fundamental recommendations put forward by the Crowther Committee. This was the unhappy proposal to develop county colleges on a nation-wide scale in about twenty years time. The Albemarle Committee reports how impressed it has been "by the abundance of evidence about the earlier maturity and at least superficial sophistication of many young people in the last school year at the secondary modern school. We know that they are restless and critical then and anxious to move out of the childish world into the freedoms of adolescence. We have been equally impressed by the failure of many children's organizations to hold their members at precisely this age, and by the need all clubs and movements feel to build a bridge between school and life in the world before the boy or girl has actually left school".

No better case for the county colleges has been made out, and the Albemarle Committee is to be complimented for its realistic attitude to the problems of the less intellectually privileged in their last year at school. This minor reform to the Youth Service, however, can in no way be regarded as a substitute for what still remains as the fundamental feature in building a real service of youth. County colleges will not only serve to make earlier transition between school and work and between immaturity and maturity, but will also be the rock around which all the Youth Service should be built.

The second recommendation could easily escape general notice. It is that, during the ten-year period of development, a sub-committee of the local education committee authority (not a sub-committee of a sub-committee) should be charged with responsibility for the Youth Service. The Albemarle Committee recommends that this sub-committee should have the advice of an advisory committee with full representation from voluntary organizations. Now that the Minister has signified his acceptance of the Report, he should see to it that local authorities do not evade their responsibilities for this recommendation. The youth sub-committees should be small and executive in character, and composed of men and women not directly concerned with any youth organizations but enthusiastic about their work. It should not be regarded as yet another committee for politically elected representatives to local councils. To the charge that, with authority to plan and administer the Youth Service, should go responsibility to the electors for public funds should come the reply that the youth committee would be directly responsible to the education committee in recommending expenditure of public monies. If this proposal is adopted, the Albemarle Committee may not only have made a most effective contribution to the establishment of a more virile Youth Service in Britain, but also the beginnings of a reform in local government, which has long been creaking in many joints.

The Countess of Albemarle and her committee are to be warmly praised for the promptitude with which they have discharged their task, and for putting forward a minimum set of practical proposals which the Government would have found difficult not to accept.

CHANCE AND PROVIDENCE

Chance and Providence

God's Action in a World Governed by Scientific Law. By Dr. William G. Pollard. Pp. 190. (London: Faber and Faber, Ltd., 1959.) 16*s*. net.

Dr. W. G. POLLARD is the executive director of the Oak Ridge Institute of Nuclear Studies in Tennessee and has also, since 1952, been a priest of the American Episcopal Church. In entering the Christian ministry from an already established career as a physicist, the greatest intellectual problem with which he was faced—a more difficult and decisive question than that of the existence of God—was, as he himself tells us, the problem of reconciling the empirico-causal attitude of science with belief in the providence of God. The present work is the result of eight years of thought about this question.

It soon became clear to Dr. Pollard that it would not do simply to seek for some residual domain of experience which was inaccessible to science and in which divine action might be located. This is the 'God in the gaps' expedient, which has suffered from the successive elimination of more and more of the gaps as scientific discovery has advanced. What he did, however, come to recognize was that the statistical character of scientific law, which has so markedly characterized the modern quantum theory, was in fact really basic even to classical physics, though this was unrecognized owing to the fact that the most tractable, and so the most fully developed, branches of science were those in which this character was scarcely evident. Illuminating examples are given from the realms of fluid dynamics (the problem of turbulent flow), ballistics and the early history of the solar system. (It may be remarked in passing that Dr. Pollard's argument has little in common with the argument by which, in the *British Journal of the Philosophy of Science* for 1950, Dr. K. R. Popper defended a quite different indeterminism in classical physics, an indeterminism which is better described as unpredictability.)

Dr. Pollard then goes on to stress the point that in history, as distinct from science, it is always the individual events that are significant; it is the *facts* that the Egyptians were drowned in the Red Sea and that Washington beat Cornwallis at Yorktown that have radically affected the subsequent course of the world's history, not the probabilities that those events would happen given the particular circumstances. This point is amplified by a discussion of the difference between scientific time, in which the origin of the time-coordinate is quite arbitrary, and historical time, in which the contrast between the unalterable past and the (as yet) undetermined future is fundamental, though it is also remarked that, with quantum theory, historical time has invaded the domain of science itself. It is also emphasized that miracle, as properly understood, is in no way contradictory to scientific explanation, for it should be thought of not as an interference with or a suspension of scientific law, but as a (scientifically) highly improbable correlation of natural causes, none of which violates any known scientific law: and, as regards allegedly unique events, such as the Creation, the Incarnation and the Resurrection, no question of chance or probability arises, for it is only in the case of events which are in principle indefinitely repeatable that the concept of probability can be applied. The book concludes with a discussion of freedom and providence, in which it is suggested that something similar to, though not identical with, the principle of complementarity in physics may be needed in other fields of science in order to remove the elements of historical time from the systems which are the object of scientific study, and the conception of the twofold nature of reality is further illustrated by the use of Dr. Martin Buber's distinction between 'I-it' and 'I-thou' relationships.

This is an important, if not entirely an easy book, and it is particularly to be commended for its author's thorough grasp of both the realms with which he is concerned—those of science and of theology—and not, as so often is the case in books on this subject, with only one of them, and for his determination to think the problems through to the end and not to be content with superficial or makeshift solutions. E. L. MASCALL

RADIOISOTOPES IN MEDICAL AND BIOLOGICAL RESEARCH

Radioisotopes in Scientific Research

Proceedings of the International Conference held in Paris in September 1957, under the auspices of the United Nations Educational, Scientific and Cultural Organization. Edited by Prof. R. C. Extermann. Vol. 3: Research with Radioisotopes in Human and Animal Biology and Medicine. Pp. xxi+763. Vol. 4: Research with Radioisotopes in Plant Biology and some General Problems. Pp. xxi+690. (London and New York: Pergamon Press, 1958.) 140s. net each.

ON looking through the voluminous publication on "Research with Radioisotopes in Plant Biology" (Vol. 4) and in "Human and Animal Biology and Medicine" (Vol. 3), one could argue whether it is useful to compile so much heterogeneous material from diverse fields of biology, only because the same technique is applied.

However, when reading the two volumes under discussion, these doubts are dispelled, for in the case of research with isotopes the common tie is not only a special technique but also a typical point of view. We might call this a new kind of dynamic biology, which only began with the introduction of the tracer techniques, and the results of which have nowhere been laid down more impressively than in these collective volumes.

The dynamic state of certain constituents of organisms is continuously being subjected to a kinetic analysis, regardless whether one examines the transport of electrolytes through the cell membrane and other general permeability phenomena, the effect of fertilizers, the synthesis of protein and nucleic acid, raw products of plants such as rubber, or the turnover of the most vital constituents of the healthy or pathological organism. The study of work in fields unfamiliar to the reader therefore acts as a stimulus for new ideas and the devising of new techniques in his own work.

Vol. 4, which is devoted to "Plant Biology and some General Problems", also comprises a series of specialized work in the field of animal physiology, so that zoologists and medical men for this reason should consult also both volumes.

It is very commendable that several papers are produced with many more useful details than were contained in the original lectures, and that techniques in particular are discussed at great length and many useful illustrations are added. OTTO HUG

PETROLEUM GEOLOGY

Geochemical Methods of Prospecting and Exploration for Petroleum and Natural Gas.

By A. A. Kartsev, Z. A. Tabasaranskii, M. I. Subbota and G. A. Mogilevskii. English translation edited by Paul A. Witherspoon and William D. Romey. Pp. xxiii+349. (Berkeley and Los Angeles: University of California Press; London: Cambridge University Press, 1959.) 94s. net.

THIS book presents a comprehensive survey of the geochemical methods of petroleum and natural gas prospecting and exploration being used in the U.S.S.R. in 1954 and reflects the large scale of the Russian effort in this field. The authors in a preface state that the changes which have taken place between publication of the Russian and American editions are mainly a matter of emphasis. However, it is probable that some of the analytical techniques have by now been modified or superseded and that methods which are briefly mentioned as being developed are now established techniques.

The standard of the translation is high but the lack of exact English equivalents for some of the Russian technical terms and the differences in Russian and English syntax has, on occasion, caused some difficulties. There are more typographical errors than should be expected in a technical book of this character, and the maps and figures, as in so many Russian publications, are often far from clear. In particular, no scales are given for the maps.

The first three chapters deal with the basic concept underlying the subject and include a more than adequate description of the geochemistry of oil formations and of gases. The remaining chapters consider geochemical methods which have proved to have a definite practical application. These include gas and core gas surveys, oil and gas logging, bitumen, bitumen luminescence, hydrochemical, radioactive, soil salt, oxidation reduction potential and microbiological methods. Various other methods which have been mentioned in the Russian literature, but which were not adjudged by a conference on geochemical methods of prospecting for petroleum and natural gas (Neftyanoye Khozyaistvo, 1955) to be of proved usefulness, are not considered.

Each method is described in the logical order of theoretical basis, field procedure, analytical techniques and interpretation of results. The equipment for various alternative sampling and analytical techniques is described in detail. Although, in general, more comment on the relative merits of the methods and techniques would have been appreciated, the authors do not hesitate to criticize those methods, whether Russian or American, with which they do not agree on theoretical grounds.

Mention is made on a number of occasions of the difficulties of distinguishing true anomalies from false anomalies resulting from biological activity and other causes. The interpretation of leakage dispersion patterns is dependent on a considerable number of variables, yet this aspect of the subject is only relatively briefly discussed. The inclusion of additional case histories presenting all the data, their interpretation and the results of subsequent drilling would have been of great interest.

The authors consistently emphasize the necessity for correlating the data from different types of geochemical methods and the results of these methods with geophysical and geological information. Geochemical methods of prospecting and exploration are not a universal panacea but are additional tools in the hands of the geologist. The geochemical prospecting methods described in this book are considered to have proved their worth under certain conditions but, as with all methods of prospecting, their application is limited to those areas where conditions are favourable.

Despite some few shortcomings, this book gives a well-balanced picture of the application of geochemical techniques and is recommended to petroleum geologists interested in obtaining a knowledge of these new and rapidly developing methods, which may give valuable additional information in the search for oil deposits. JOHN S. TOOMS

GROWTH OF PRIMARY EDUCATION

Primary Education

Suggestions for the Consideration of Teachers and Others concerned with the Work of Primary Schools. Pp. xiii+334. (London: H.M. Stationery Office, 1959.) 10*s*. net.

THE development of efficient methods of teaching in primary schools, improved organization of the schools themselves, and a markedly greater degree of achievement by the children have resulted from a widespread and quickening interest in primary work by teachers and the general public. This is well brought out in this Ministry of Education publication, which shows that the rise in children's achievements has not come about suddenly or by mechanical application of any special methods or practice, but because teachers, from their experience and from the growing body of research available to them, have come to understand better the ways in which children learn, and have applied their knowledge to good purpose.

The book is in effect an anthology of the ideas and practices which present-day teachers are successfully developing in the schools.

Twenty years ago junior schools were only tentatively striking out towards what is now common practice. Less than half the children between eight and twelve years of age were in schools separate from those containing older children also. Now, more than nine-tenths of school children up to eleven years of age are in separate infants schools, separate junior schools, or schools for children between five and eleven only.

'Primary Education' calls for a more critical consideration by teachers of the quality and substance of what is offered to the children for their learning, and for a firmer realization that children's capacities, whether small or great, should be exercised to the full.

For the man of science, one of the most interesting sections is that concerned with the teaching of mathematics. There is little doubt that deficiencies in the primary school must bear considerable responsibility for subsequent failures in mathematics. Teachers in primary schools can do much to prevent the positive dislike of mathematics which is so common in older children. It is to be hoped that the new three-year training college courses will produce primary school teachers who can get away from teaching mathematics by rote and will be able to teach young children in a meaningful way.

CONURBATIONS OF GREAT BRITAIN

The Conurbations of Great Britain

By T. W. Freeman. With a chapter on the Scottish Conurbations by Catherine P. Snodgrass. Pp. xii+393 (66 maps). (Manchester: The University Press, 1959.) 37*s*. 6*d*. net.

PATRICK GEDDES' term 'conurbation', more narrowly defined by Fawcett, is a vitally important but vague geographical concept that calls for searching analysis of criteria and their cartographic representation. For this reason we turn to this book with special interest.

As to content, Chaps. 1 and 12 should be read first. Then those of the intervening chapters about the conurbations (or the ensemble of minor conurbations) of most interest should be read. For the book is heavy in topographical detail that becomes irksome in spite of the aid of maps. The sectional treatment of each conurbation includes physical features, historical growth, distribution and movements of population, and, a main feature, the growth of the patterns of administrative areas. The work depends on geographical and historical studies as well as on the interesting data contained in reports of past commissioners and the census reports. It contains 66 maps, 25 of which show the changing patterns of the administrative areas in each conurbation.

Freeman, following Fawcett, has attempted to define every conurbation by the extent of its built-up area. There are seven major conurbations, each of which receives a separate chapter in the book. Fourteen minor conurbations have 250,000–750,000 inhabitants. These include several 'clusters' of special interest—the South Wales valleys, Sheffield–Rotherham (Geddes' South Riding), the Lancashire Coalfield (Wigan–St. Helens), and the Potteries. Some of these areas already form more extensive and almost contiguous clusters, as envisaged by Geddes. The whole South Wales area (Geddes' Waleston) has 1·1 million people. Nottingham and Derby are also linked with 850,000. The Sheffield and Barnsley areas are virtually one. Manchester and Liverpool are interconnected through the Lancashire coalfield area (Geddes' Lancaston). The smaller conurbations (50,000–250,000), 75 in number, are treated in two chapters. Portrayals are necessarily brief and encyclopædic.

This book is essentially a descriptive compilation. This is how Freeman chose to write it; but the approach will not advance geography as a research discipline or as a contributor to planning. He does not formulate and systematically develop any geographical concepts with regard to urban growth, an approach that would necessitate a complete reorganization of the book, but would yield more worth-while results. Geographers need to concentrate on particular problems in the spatial structure of our urban society, some of which are sandwiched in the pages of this book. Here are involved questions of criteria, cartographic analysis, and interpretation that cry out for investigation, and are especially fitted to the expertize of the geographer. The defects of this book point to this need, and it is to be hoped that Freeman and his colleagues will apply themselves to it.

R. E. DICKINSON

STUDIES IN RHEOLOGY

Transactions of the Society of Rheology

Vol. 2. Edited by R. D. Andrews. Pp. ii+314. (New York: Interscience Publishers, Inc.; London: Interscience Publishers, Ltd., 1959.) 64*s*.

Rheology of Disperse Systems

Proceedings of a Conference organized by the British Society of Rheology, and held at the University College of Swansea, September 1957. Edited by C. C. Mill. Pp. vii + 223. (London and New York: Pergamon Press, 1959.) 60*s*. net.

THE "Transactions of the Society of Rheology" constitute the proceedings of the annual conferences of the American Society. In 1957, the conference was held in the Textile Research Institute, Princeton, New Jersey. The second of these volumes contains sixteen complete papers and a number of abstracts.

The organizers are to be congratulated on the excellent balance of the programme. It would be tempting to give a heavy preponderance to papers dealing with work in the one or two industries which now employ a high proportion of rheologists; but this has not been done. Theory and practice over a wide field are discussed.

In an introductory paper, A. S. Nowick outlines the career of C. M. Zener, who received the Bingham Medal. Dr. Zener is distinguished in other fields, and it is estimated that his rheological work constitutes less than half his scientific output.

On the more academic side, the subjects treated include work on viscosity–concentration relations in suspensions, relaxation spectra distributions of high polymers, equations for the interconversion of relaxation and retardation spectra and a general study of capillary viscometry.

Papers on applied rheology range over a wide field: the peeling of adhesive tapes, liquid flow in roll nips, creep of snow, mechanical breakdown of bundles of fibres and a fair number of articles on high polymers.

The paper by A. B. Metzner and M. Whitlock is worthy of special mention. Since Osborne Reynolds published his classical work, it has been well known that certain pastes and suspensions become firmer on shearing. All such phenomena have tended to be classed as 'dilatancy', it being assumed that closely packed particles must first pass into open packing before the system can flow, thus producing an increase in volume. This paper confirms what has long been suspected, that the increase in consistency is not necessarily associated with dilatancy at all and often happens at concentrations not corresponding to close packing. The true explanation remains an outstanding problem for rheologists.

The 'Transactions' will certainly provide an excellent annual survey of the progress of rheology in the United States. It is a pity only that this particular volume has taken so long to appear.

It is difficult to review a collection of eleven papers which, though they are all concerned with dispersed systems (must one omit the grammatically required 's' ?), cover so wide a range of subjects and materials. Yet it is fair to say that, though the standard of the articles differs considerably, the general level is remarkably high.

Prof. J. G. Oldroyd's presidential address deals with the mathematics of 'complicated rheological properties', because, as he points out, simple properties are of little interest to the mathematician. This is fortunate, in view of the complexity of the materials generally studied by practical rheologists.

S. G. Mason and W. Bartok contribute a paper of considerable theoretical interest on the hydrodynamics of suspensions and emulsions, and R. L. Whitmore gives some reasons why, on theoretical grounds, suspensions flowing through capillaries fail to obey Poiseuille's fourth-power law, applying his theory to the very important problems of the flow of blood. Since this paper was read, it has stimulated considerable further work. Also N. Casson's and E. Bantoft's contributions, in which they propose a very simple but hitherto unused equation to relate shear stress to rate of shear, has been followed by the publication of descriptions of a number of applications to materials other than varnishes and inks, including blood and molten chocolate. The latter forms the subject of an article by E. H. Steiner, but it was after the conference that he discovered the usefulness of Casson's equation for this material.

A. Jobling and J. E. Roberts, using Weissenberg's deformable membrane technique, describe complex dilatancy effects in certain suspensions which still elude any mechanical explanation and yield a strong incentive to further study. Other papers deal with high polymers, adhesive sealing compositions ('lutings'), starch-clay mixtures and gaseous fluidized beds. This is clearly a conference which immediately activated further research, thus fulfilling the prime purpose of all such gatherings.

The publishers are to be congratulated on the excellent production of the book. A welcome appendix gives the addresses of all authors and contributors to the discussions.

G. W. SCOTT BLAIR

TERCENTENARY CELEBRATIONS OF THE ROYAL SOCIETY

THE programme of events which are to comprise the tercentenary celebrations of the Royal Society, due to take place during July 18–26, indicates that not only is the historical importance of the event to be appropriately marked but also that those who are to take part will have a good opportunity to become acquainted with active research work now being carried out in Great Britain.

Formal participation in the full programme will be limited to Fellows and Foreign Members of the Society and to those already invited to represent at the celebrations national academies of science, selected universities throughout the world, and appropriate international scientific organizations. The majority of the Foreign Members of the Society have already notified their intention of being present, and other distinguished men of science are among those who are coming from some fifty different countries. The British Commonwealth will be particularly well represented by large numbers, many of whom are Fellows of the Royal Society. The presence in London of so many leading scientists promises to make the occasion an outstanding scientific event.

In addition to the formal participants and their accompanying relatives, for whom the full programme of events has been principally devised, there will be a number of events to which others will be invited, notably the formal opening ceremony on the afternoon of July 19, which is to take place in the Royal Albert Hall. The ceremony will take the form of a few short speeches and the presentation of formal congratulatory messages by selected representatives attending the celebrations. For the occasion, Sir Arthur Bliss, Master of the Queen's Musick, is composing a "Salute to the Royal Society", and this will be played by Dr. G. Thalben-Ball on the organ together with the trumpeters and other musicians from the Royal Military School of Music, Kneller Hall. After an interval for tea the Society's president, Sir Cyril Hinshelwood, will deliver the tercentenary address.

In honour of the occasion the Universities of Oxford, Cambridge and London will have special honorary degree ceremonies, when degrees will be conferred on distinguished scientists attending the celebrations.

The Oxford and Cambridge ceremonies will take place on July 21 and July 25, respectively, during visits to these Universities. While in Oxford, visits will be paid to the Colleges which will receive the Royal Society visitors at lunch. The conferment of honorary degrees will take place in the Sheldonian Theatre, the architect of which was Sir Christopher Wren, former president of the Royal Society, and this will be followed by a garden party at Wadham College, where meetings of importance in relation to the foundation of the Society took place. John Wilkins, Bishop of Chester and Warden of Wadham, was one of the Society's first secretaries. The visit to Cambridge will have a similar pattern, and in both Universities special exhibits relating to former Fellows of the Society are being specially arranged.

The University of London ceremony will take place in the Royal Festival Hall on July 22, where H.M. Queen Elizabeth the Queen Mother as Chancellor of the University will confer honorary degrees.

The following lectures will be delivered during the period of the celebrations in the Royal Institution, the Royal College of Surgeons, and the Beveridge Hall of the University of London: "Genetics and the Structure of Biology", by Prof. C. D. Darlington; "Trends in Aeronautical Science and Engineering", by Sir Arnold Hall; "The Evolution of Nuclear Power Plant Design", by Sir Christopher Hinton; "The Physics and Chemistry of Nervous Conduction", by Prof. A. L. Hodgkin; "Molecules in Crystals", by Dr. Dorothy Hodgkin; "The Investigation of the Universe by Radio Astronomy", by Prof. A. C. B. Lovell; "The Problems of Transplantation", by Prof. P. B. Medawar; "The Study of Nuclear Interactions at Very Great Energies", by Prof. C. F. Powell; "New Horizons in Organic Chemistry", by Sir Alexander Todd; "The Metamorphosis of Insects", by Prof. V. B. Wigglesworth.

The programme includes visits to university, government and industrial research laboratories which are or have been associated with the work of Fellows of the Society. In addition to visits to the Universities of Oxford and Cambridge, there are formally organized visits to the Imperial College of Science and Technology and University College in London, as well as informal visits privately arranged. The National Physical Laboratory, the Royal Botanic Gardens, Kew, the National Institutes for Medical Research, for Research in Nuclear Science and for Research in Dairying, as well as the Royal Aircraft Establishment, the Atomic Energy Research Establishment, the Geological Survey and Museum, and the Radio Research Station and Road Research Laboratory (Department of Scientific and Industrial Research) are among the national research institutions to be visited. The British Museum (Natural History) and the Science Museum are arranging special visits. The Associated Electrical Industries, Ltd., Research Laboratory at Aldermaston, the British Petroleum Research Centre, the General Electric Co. Research Laboratories, the Glaxo Research Laboratories, Imperial Chemical Industries, Ltd. (Plastics Division), the Wellcome Research Laboratories, and several research association laboratories provide a quota of industrial research visits.

Other events or visits recall the historical associations of the Society. The foundation of the Society in Gresham College near Guildhall in the City of London will be commemorated not only by two City receptions, one by the Lord Mayor in Guildhall and the other by the twelve great City Companies in the Mercers' Hall, but also on Sunday, July 24, by a sermon relating to Sir Christopher Wren, to be preached in St. Paul's Cathedral, of which he was the architect. One of the tours will re-visit the present-day Gresham College and also the other former homes of the Society in Crane Court off Fleet Street and Somerset House. Visits to Greenwich, where King Charles II instituted the Royal Greenwich Observatory, and the Chelsea Royal Hospital, built by Wren on a site once briefly owned by the Royal Society, are direct links with the Society's Royal founder. The Royal Mint, where Newton presided as master for many years, and Newton's birthplace at Woolsthorpe are also included in the places to be visited.

The Shell International Petroleum Company is making a special film for the occasion. This will be shown in the Royal Festival Hall on July 22, in a programme which will also include reference to the value of the film as a tool in scientific research. At the Society's tercentenary conversazione, to be held in Burlington House on July 23, a series of exhibits giving a presentation of current research work will be included in the programme of the evening, during which there will also be on display the congratulatory addresses received by the Society on the occasion of its three hundredth birthday. Some of the Society's treasures, such as the original reflecting telescope made by Sir Isaac Newton, the manuscript of Newton's "Principia", the Society's Mace and the Charter Book, both of which are gifts from the Society's Royal founder, will also be displayed on this occasion.

The celebrations will conclude with the tercentenary banquet on July 26, when the toast of "The Royal Society" will be proposed by the Prime Minister.

The issue of the first volumes of "The Correspondence of Isaac Newton", edited by Prof. H. W. Turnbull, happily coincides with the tercentenary year of the Society as a tribute to the Society's greatest Fellow. Two further historical works are being specially issued to mark the tercentenary occasion. These are a new brief history of the Society by Prof. E. N. da C. Andrade, and a volume of the Society's *Notes and Records* which is edited by Sir Harold Hartley. This special volume will give an account of the founder Fellows including Robert Boyle, Christopher Wren, Sir Robert Moray, Viscount Brouncker, Robert Hooke and others, as well as articles on the origins of the Society.

D. C. MARTIN

SOME CONSEQUENCES OF EXPANSION OF THE EARTH

By PROF. J. TUZO WILSON

Department of Geophysics, University of Toronto

IN 1937 Dirac[1] suggested that the gravitational constant G is decreasing with time, proportionally to t^{-1}, where t is the age of the universe. At that time t was considered from astronomical evidence to be about 2×10^9 years, although age determinations indicated a greater age.

In two recent papers Dicke[2,3] has discussed some of the consequences of this hypothesis using more recent estimates for t of $6\cdot5 \times 10^9$ and 12×10^9 years, respectively. Using the first figure he concludes that in the past $3\cdot25 \times 10^9$ years the circumference of the Earth would have increased by about 4·5 per cent or 1,100 miles at an average rate of about 0·5 mm. a year. He suggests that this expansion should still be recorded in cracks widely distributed over the ocean floors. He also finds no compelling evidence of a physical nature for or against Dirac's hypothesis and speculates whether "the history of the solar system as seen through the eyes of astronomers and geologists may enable fundamental conclusions to be drawn regarding physical interactions in the past". Egyed[4] is another who has long advocated an expansion of the Earth on geological grounds and has estimated a rate of increase in circumference of 3·8 mm. a year.

It is proposed here to examine the geological and geophysical evidence briefly in the light of recent observations.

The information about the Earth has been chiefly contributed by stratigraphers, Precambrian geologists, students of physics of the Earth and oceanographers studying the sea-floor. Unfortunately, it has never been well integrated.

As a result of the International Geophysical Year, progress in oceanography has recently been very rapid. In 1956 Ewing and Heezen[5] suggested that the mid-ocean ridges form a continuous, seismically active belt, extending through the Atlantic, Indian and South Pacific Oceans. They[6] have since stated that a median rift valley already noticed by Hill[7] is a characteristic feature, that it may be the locus of the earthquake foci, and that it (and perhaps the ridge in general) have intense magnetic anomalies "due to a subsurface body of high magnetic susceptibility". A branch of this rift has been traced to the Gulf of Aden[8] and thence to the rift valleys of Africa[9], which have similar geophysical features.

Heezen[10] suggests that the African rifts represent the start of another ocean and that existing ocean basins may have grown by the widening of such rifts under tension, "if, as the Earth's exterior expanded, the continental crust maintained a relatively constant area". Since the oceans occupy more than two-thirds of the Earth's surface, such an expansion would involve nearly doubling the Earth's radius during geological time. The impossibility of this has been pointed out by Teller[11] and is appreciated by Heezen, who mentions that the postulate of an expanding Earth "may have other more serious objection of an astronomical nature".

If, on the other hand, one postulates that only the mid-ocean ridges and not the whole ocean basins have grown, the expansion would have been much less. Their width varies and is not accurately known, but Heezen's estimates seem to range from 400 to 800 miles. The length of the active ridges is 40,000 miles; but echo-soundings by U.S. Submarine *Nautilus* suggest a continuation of the mid-Atlantic ridge across the Arctic basin, parallel with the Lomonosov ridge[12], and it has been suggested that some mid-Pacific ridges form part of the system, although seismically quiescent at present[13,14]. Including these gives a minimum length of the ridges of 60,000 miles and a minimum superficial expansion of about $2\cdot4 \times 10^7$ square miles. This would require an increase in the Earth's circumference of about 6 per cent, and the formation of the ridges has probably required all geological time because there are no important abandoned ridges or any obvious way of disguising them. This is close to Dicke's estimate. This does not prove that expansion of the Earth has occurred or if it has that it is due to change in G, but it is worth considering some of the consequences of accepting that hypothesis.

Bullard[15], who devised a method of measuring heat flow through the ocean floor, and Von Herzen[16] have remarked that over most parts of the ocean floor the flow of heat is equal to that on continents but that it is higher over the mid-ocean ridges. This would be explained if horizontal separation of the original crust along the ridges continually exposed hotter interior layers. This high heat-flow and the absence of any earthquakes of focal depth greater than 70 km. along the ridges suggest that the Earth is only brittle to stresses of short duration to a depth of 70 km. beneath the ridges.

The lower temperature gradients and the occurrence of earthquakes at depths of up to 700 km. under other parts of ocean floors and continents suggest that those parts may be brittle to 700 km.

The alternative explanation that rising convection currents cause the high heat flows is as satisfactory for the mid-ocean ridges, but it has never been shown how sinking currents could account for the very varying types of coasts of different oceans or the patterns of mountain belts. Reduced heat flows found in some trenches could be due to recent flow into them of cold turbidity currents and submarine oozes.

Since the distance to the zone of flow under the mid-ocean ridges may be only one-tenth as much as it is elsewhere, we might expect a rift once formed to remain the site of further expansion.

Opening of rifts along the mid-ocean ridges would tend to make the rest of the Earth's surface buckle at a distance from them. That is where the continents with their mountain system are found. There the increase in radius of curvature would produce local compression above a level of no strain (or neutral surface) along with tension below it. A similar general situation was postulated by Jeffreys[17] as a result of contraction in the Earth, and it was used by Scheidegger[18,19] and Wilson[14,20] to explain the details of mountains, island arcs, grabens and other features. Their explanations are still applicable in principle to the new hypothesis. At the same time, since the brittle shells on the Earth's surface are spherical not cylindrical, the buckling which is considered to produce mountain building would shift in direction as well as in position from time to time. It is conceivable that this change every few hundred million years might be as large as a right angle (for example, from Ural or Appalachian directions to Himalayan or Cordilleran directions), while minor adjustments and seismicity might be expected everywhere.

The view that continents are zoned and have grown during geological time over parts of the former ocean floors[14,21] is compatible with this hypothesis. Indeed expansion removes a major obstacle to this theory. If continents had grown on a shrinking Earth, the oceans would have flooded the continents, and this has not happened.

Recent work[22] on the isotopic ratio of lead ores having volcanic associations also supports the view that they (and hence by analogy other volcanic rocks) have not been reworked but are being emplaced directly from the mantle. This supports the opinion that continents are growing and not being reworked.

The observation that continents are spaced as far from mid-ocean ridges as possible and that there is some parallelism between their margins could be a consequence of the conditions necessary to produce buckling.

The view that continents have drifted apart is supported to a small degree but not to the extent desired by some advocates of continental drift and some students of palæomagnetism. Nevertheless, expansion along the ridges would alter the Earth's principal moments of inertia and could thus induce polar wandering.

One of the chief arguments used in support of convection currents has been that they might explain the rapid horizontal motions observed along large faults such as the San Andreas in California, and the horizontal first motion observed in circum-Pacific earthquakes, although the manner in which they could do this has not been explained. But such motions are also a consequence of the present hypothesis. An active mid-ocean ridge extends across the South Pacific Ocean from the vicinity of New Zealand to South America, where it terminates in two or three branches against the Andes. If this ridge is widening at the rate of about 0·5 mm. a year and if along the Andes and Cordillera there is an existing line of fracture due to buckling, then a northward shearing motion of the Pacific Ocean relative to the Americas could take place along the mountains north of the ridge. Such a northward motion of the Pacific has long been postulated, and the rate is perhaps compatible with the rather uncertain geological evidence[23].

That this shear motion would not occur south of Chile may perhaps explain the absence of any equivalent to the Isthmus of Panama across Drake Passage. Similar motions in the past could account for other shifts, such as those along the Great Glen fault[24] or the Murray scarp[25].

Isostatic balance would certainly be effective in the model Earth proposed, but adjustment would be more readily achieved for the Earth as a whole and for sea-mounts over mid-ocean ridges than elsewhere. This appears to be supported by observations. The suggestions from studies of Earth satellites that the Earth is somewhat pear-shaped[26] might result from the wider distribution of mid-ocean ridges in the southern hemisphere; but it appears to be more easily explained by the recent removal of ice-sheets. Contrary to previous opinion, Sacks and Strelkov[27] report that large ice sheets covered much of northern Siberia during the Pleistocene. Thus the geoid is still much depressed in a zone centred along latitude 60° N., and G. Pratt[28] has reported depression over Antarctica. This would produce a pear-shape without implying great strength over periods of long duration.

It is perhaps worth noting that to a first approximation the mid-ocean ridges lie in the shape of a reversed J folded about the Earth, the stem being in the Atlantic and hook being in the Southern Ocean. Two branches extend northward into the Indian and Pacific Oceans. Also to a first approximation the continents lie in a similar but complementary pattern of a J inverted and folded about the Earth with the stem through Antarctica and the Americas and the hook through Eurasia. Two branches extend southwards into Africa and Australia.

Perhaps this was the initial fracture pattern of the Earth; but the two parts have developed differently. Whereas the mid-ocean ridges have parted without migrating and have emitted basalts, the continental fractures have buckled without parting and have migrated, moving outwards about their nuclei which seem to preserve evidence of a different, more volcanic and perhaps hotter history of the Earth during a period 2,000–3,000 million years ago[30,31]. It is only the average position of the continental system that at all resembles a *J* for to-day the active fractures have the shape of a *T*, folded about the Earth with its junction in Indonesia, but there are links between the two systems, for example, between Gibraltar and the Azores, between New Zealand and the ridge to the south and in the scarps from California to Hawaii. The volcanoes of the continental system emit more acid lavas than basalts.

Thus the foregoing hypothesis has the merit of appearing to explain many features of the Earth's surface, though this does not constitute a proof. Even if true, expansion at the rate here postulated could conceivably be due to phase changes[19] in the Earth's interior or perhaps to differentiation[30] of the core and mantle, but a decrease in *G* remains an inviting idea. If so a number of geophysical effects discussed by Dicke must be taken into account in calculations about the Earth's interior and these might include secondary effects due to phase changes.

I am indebted to colleagues in the Departments of Physics at the University of British Columbia and Toronto for suggestions and particularly to Profs. G. M. Volkoff and W. H. Watson.

EXPERIMENTAL TRANSFORMATION OF CELLS*

By Dr. HONOR B. FELL, F.R.S.†

Strangeways Research Laboratory, Cambridge

THE term 'transformation' will be used rather loosely to cover a wide range of changes produced by various experimental conditions in the structure and functional activities of cells; merely toxic effects leading to degeneration have been excluded. Most of the examples presented have been chosen from experiments on tissues and cells grown in culture, because I myself am familiar with this field.

Part of the work to be described relates to the normal differentiation of tissues, and has been included because it sheds light on some of the morphogenic principles that are concerned in certain types of cellular transformation.

Tissue Interaction

It is now known that the different types of cells of which an organ is composed may exert a profound influence on one another's structure and physiology, especially in embryonic life.

In Spemann's classical experiments on induction it was shown that in early newt embryos certain tissues act as organizers in embryonic development and induce and direct the differentiation of neighbouring structures. That this phenomenon of induction also occurs in warm-blooded animals was first demonstrated by Prof. C. H. Waddington[1] in early chick embryos explanted in culture.

Induction is not restricted to the initial stages of development; an interesting example of its operation at a later stage of embryonic life is provided by the elegant experiments on the formation of feather rudiments, recently published by Dr. P. Sengel[2] from Prof. Etienne Wolff's laboratory. The object of this work was to investigate the interaction of the dermis and epidermis during the development of the feather papillæ. First, Sengel cultivated dorsal skin from chick embryos of 6–6½ days incubation on a very simple medium; he found that under these conditions feather germs would not develop in an explant in which no feather germs had yet appeared (stage 0) unless it were associated with another tissue—neural tube, muscle, etc.; but feather rudiments formed readily in slightly older (stage 1 and stage 2) skin explants. He concluded that at stage 0, feathers would not develop in the absence of certain non-specific external factors which were unnecessary at a later stage. Next, Sengel separated the epidermis from the dermis by Moscona's method of mild tryptic digestion, and then combined stage 0 epidermis with stage 1 dermis: feather papillæ formed in the double explants. No feathers appeared, however, when stage 0 epidermis was associated with slightly older, stage 2 dermis. From this it was concluded that at stage 1 the dermis can induce feather-formation, but that by stage 2 it has lost this inductive capacity. Sengel then combined stage 2 epidermis with stage 0 dermis: feather germs developed; this result showed that by stage 2 the epidermis had acquired the power to induce the early (stage 0) dermis to form feather papillæ.

---

* Substance of a Special University Lecture delivered in the Anatomy Department, Middlesex Hospital, London, on February 2.

† Foulerton Research Fellow, Royal Society.

These results are a nice example of the reciprocal influence of mesoderm and epithelium during normal development. When isolated epithelium is associated with the wrong mesoderm, however, its differentiation may be profoundly disturbed. Thus Sengel[2] found that when the dorsal epidermis from a stage 1 (6-day) embryo was associated with the tarso-metatarsal dermis of a 12-day embryo, scales developed and the grafted epidermis became transformed into the thick, precociously keratinized epithelium normally characteristic of the shank region.

My former colleague, Dr. C. B. McLoughlin (unpublished work), investigated the influence of mesenchyme from different organs on the differentiation in culture of epidermis isolated by tryptic digestion from the limb-buds of 5-day chick embryos. In control experiments isolated epidermis when combined with limb-bud mesoderm formed an islet of keratinizing squamous epithelium, but when associated with the mesoderm of the gizzard, it failed to keratinize and formed a cuboidal epithelium which sometimes contained ciliated cells and even secreted a little mucin. When enclosed by heart muscle, the epidermis again failed to keratinize and formed a cyst of extremely flattened cells.

The interaction of epithelium and connective tissue in more complex organs has been studied by Grobstein. One set of experiments concerned the submandibular gland rudiment of 13-day mouse embryos[3]. Grobstein separated the epithelial component of the gland from the mesodermal rudiment of its capsule. He found that when the isolated epithelium alone was explanted, it grew as an undifferentiated sheet of cells; when combined with mesoderm from other parts of the body it formed an inactive, rounded mass; but when re-combined with its own capsular mesoderm it formed a branching, glandular tree. Grobstein obtained exactly the same results when he interposed a porous filter between the epithelium and the mesenchyme, although the pores of the filter were too small to allow cells to pass through. From this it was clear that the glandular epithelium requires substances produced by its own capsular cells to allow it to differentiate normally, but that direct contact with the mesenchyme is not essential.

Chemical Influences

This brings us to the subject of transformations induced experimentally by chemical means.

The best known and most widely investigated example of a chemical compound that drastically affects differentiation is vitamin A. In A-deficient animals, many mucous and glandular epithelia acquire a squamous, keratinizing structure very similar to that of the normal epidermis. A similar histological change (unpublished) was recently produced by my colleague, Dr. I. Lasnitzki, who found that when the prostate glands of young mice were grown for 10 days in a protein-free, chemically defined medium containing neither vitamins nor hormones, they developed large areas of heavily keratinized, squamous epithelium which was often continuous with apparently normal secretory epithelium. It is possible, but not yet certain, that this change may be due to the absence of vitamin A in the culture medium.

The late Sir Edward Mellanby and I found that the reverse effect to that of A-deficiency could be produced by growing embryonic chicken skin in a medium containing excess vitamin A (ref. 4). In normal medium the epithelium develops into a squamous, keratinizing epidermis, but in the presence of excess vitamin A it is changed into a mucus-secreting epithelium which is sometimes ciliated.

Dr. McLoughlin (unpublished work) has shown that this response of the epidermis to vitamin A is due to a direct action on the epithelium and is not mediated by the dermis. Pure cultures of epidermis isolated from 5-day chick embryos became keratinized in normal medium, but in the presence of vitamin A it failed to become keratinized and secreted some mucin.

Dr. Stephen Pelc and I[5] investigated some of the early histochemical changes that accompany this mucous transformation, by studying the uptake of various labelled compounds by means of autoradiography. We found that of the amino-acids, leucine and methionine were taken up equally well by the epidermis in the presence or absence of added vitamin A; but the vitamin reduced the incorporation of tyrosine in the superficial cells, and greatly diminished the uptake of cystine throughout the epithelium; these effects are probably correlated with the inhibition of keratinization. The uptake of inorganic sulphate was studied since in animals it is incorporated into mucopolysaccharides but not into amino-acids. In the deeper layers of the epithelium there was little difference in uptake between the A-treated and control explants, but in the superficial cells incorporation was very slight in the keratinizing controls but rapidly increased in the A-treated skin as secretory activity developed. This suggests that in the normal skin the basal cells have a mechanism for synthesizing mucopolysaccharides, that this is blocked by keratinization but that it continues to act when keratinization is stopped by excess vitamin A. It was interesting that whereas in the controls the uptake of tritium-labelled thymidine was restricted almost entirely to the basal nuclei, in the A-treated epidermis labelled nuclei occurred at all levels. It is unlikely that any of these histochemical changes represent the fundamental action of vitamin A on the epidermis.

Another group of chemical compounds that readily produce metaplastic changes *in vivo* are the carcinogens.

Spontaneous Transformation in Cell Cultures

Finally, a brief reference will be made to a rather different type of transformation that is well known in cell culture work. To prepare cell cultures, tissues are dissociated by enzymatic digestion, and the liberated cells are grown in flasks, tubes or bottles in an undifferentiated, very actively multiplying state, sometimes for many years. In order to survive indefinitely under these very unnatural conditions, the cells adapt themselves in various ways, so that usually they come to differ widely in appearance, behaviour and metabolism from cells of the same histological type freshly isolated from the body.

An interesting and important feature of these so-called transformations in long-term cell cultures is that they sometimes end in malignancy. Dr. George Gey[6] maintains two strains of rat fibroblasts derived from the same explant: one produces malignant tumours when implanted into rats, the other does not. Dr. Sanford and her colleagues, working in Dr. W. Earle's laboratory, have two strains of cells, both descended from the same single mouse fibroblast[7]. After 1½–2 years in culture, one of these sister lines, called the 'high' strain, when grafted into mice produced lethal sarcomas in 97 per cent of the animals, while the other, termed the 'low' strain, produced sarcomas in only 1 per cent of the mice. The two strains differ in habit of growth and in metabolism, that of the 'high' strain being largely anaerobic and that of the 'low' strain almost normal, yet their antigenic properties are the same and either can immunize against the other.

Conclusions

How far are we justified in using the term 'cellular transformation' ? Tissues certainly are transformed, but are the individual cells ?

I know of no example of a structurally differentiated cell being directly changed into one of a different histological type. In the early embryo, a wide spectrum of developmental changes can be experimentally induced in the tissues, because all the component cells are at a very early stage of differentiation. When older tissues are subjected to morphogenic influences, the fully differentiated cells are not transformed but usually degenerate and are shed. The metaplastic change in the tissue is due to the fact that the structurally undifferentiated germinative cells are potentially capable of following more than one developmental path ; which path they choose depends on their threshold of response to the particular environmental conditions to which they are exposed. In the normal animal, a striking instance of the germinative cells of an epithelium switching alternately from one developmental pathway t another is provided by the vagina : during diœstru the basal cells differentiate into mucous elements but when exposed to the influence of œstroge they form a squamous, keratinizing epithelium instead and the mucous cells are shed.

As Dr. Paul Weiss[8] has pointed out, the germinativ cells of older tissues are not really undifferentiated since their developmental repertory, though wider tha is sometimes realized, is nevertheless extremel limited as compared with that of early embryoni tissues.

Personally, I do not think that we can conside this switching of germinative cells from one develop mental pathway to another as a transformation i the strict sense of the word. As regards the type o 'transformation' that occurs in unorganized cel cultures, it is still uncertain whether the changes tha appear in the cultures represent a real transformatio of the cell population as a whole, or whether the are due to the selection of variant cells that ar peculiarly well adapted for growth in this grossl abnormal environment. I think that sometime at least, selection is the more probable explanatio of the phenomena observed.

FOURAH BAY COLLEGE: UNIVERSITY COLLEGE OF SIERRA LEONE

By Dr. F. J. TAYLOR
Head of the Department of Botany
AND
Dr. E. DOWNING
Head of the Department of Chemistry

ON January 28, His Excellency Sir Maurice H. Dorman, governor of Sierra Leone and deputy visitor of the College, presented the Royal Charter to Fourah Bay College, incorporating it as the University College of Sierra Leone. Thus was inaugurated a new phase in the development of the College, although it has functioned as a university college for more than eighty years.

Fourah Bay College itself was founded in Freetown in 1827 by the Church Missionary Society. Before that, in 1816, a precursor of the College, the 'Church Institute', had been founded by the Church Missionary Society in the village of Leicester, just outside Freetown. This became a 'Seminary' in 1819 and moved to another village, Regent, in 1820. Its main function, and that of the early Fourah Bay College, was the training of evangelists in the belief that any continuous evangelistic work in West Africa should be undertaken by Africans.

The ambitiousness of the establishment of the College may be gauged from the fact that although a township with European traders had been establishe on the site of Freetown in the fifteenth century, th Colony of Sierra Leone was only established in 180 with a population mainly of freed slaves who wer brought from Nova Scotia in 1792 (they had fough for the British in the American War of Independenc and were dissatisfied with their rewards of grants o land in Nova Scotia) and from Jamaica in 1802. I the following years the population was increased by large number of Africans liberated from capture slave ships. Most of these were not acceptable by th more cultured repatriates from the United State and were established in villages along the coast of th Colony and in the hills above Freetown.

In 1827 the College was established with si students in a house that had at one time housed slave dealer. Though numbers were small, th students soon achieved prominence in West Africa affairs. One of the first students was Samuel Crowthe who qualified, became a teacher for some years, an then returned to the College as a tutor. In 1841 h and the Rev. J. F. Schon led the first Niger Expedition, and on his return he went to England, where he was ordained in 1843. He returned to Sierra Leone, and then proceeded to his native Nigeria, where he pioneered the spread of Christianity, and was consecrated Bishop of Lagos in 1864—the first African bishop of modern times.

During the Victorian era, the College was cosmopolitan, drawing its tutors from England, Africa, the United States and Germany; the first Principal was a Swiss. But teaching was not the sole occupation of the staff. Grammars, dictionaries and translations of the African languages came out of Fourah Bay. Of these, Koelle's "Polyglotta Africana" (1854), a comparative study of a great number of West African languages, is still a basic work.

By the early 1840's the number of students was more than thirty and the accommodation too cramped. A new building was initiated and was completed in 1848. This was sited on the isthmus between Fourah Bay and Destruction Bay (where the captured slave ships were broken up). This building, which still stands, housed the College for nearly a hundred years.

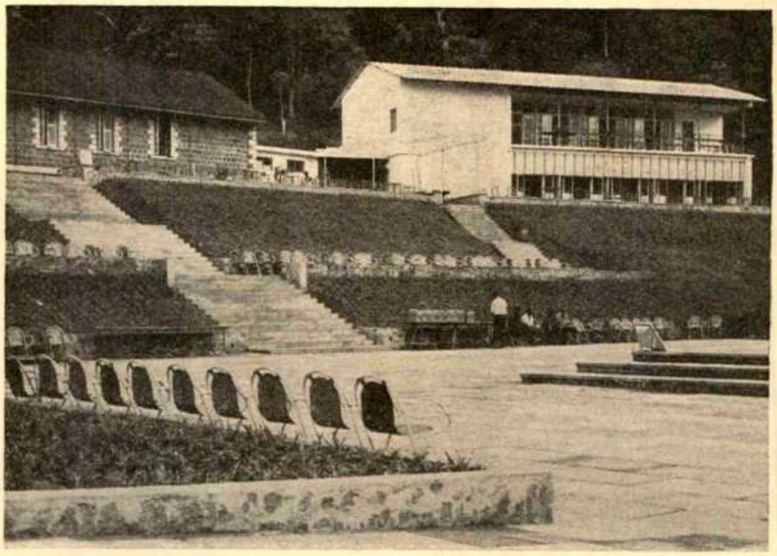

Fig. 1. The Students' Union. On the left is one of the original buildings of the hospital; on the right part of the new Union building. In the foreground is the Assembly Arena (Photo: T. Lloyd)

In 1870, the Rev. R. Sunter became principal, and he inspired the Church Missionary Society to extend the scope of the College to include the liberal arts as well as classics and theology. Suggestions that Fourah Bay College should be affiliated to an English university were made, and in 1876 affiliation to the University of Durham was established, whereby students could be admitted to any degree, diploma or licence of that University. At this time Sunter introduced extra-mural classes and some science teaching with the aid of Colonial surgeons who became part-time lecturers. Mathematics, and a little later geography, were subjects for degree courses.

In those days optimism in Sierra Leone was abundant, and the country was talked of as the place where West African development would start. There was even talk of a West African university developing from the College. The graduates of Fourah Bay College, with the standing of a British university degree, went out into the West African world and prospered, filling important posts in government, law, teaching, medicine, and the church.

However, the missionary finances started to dwindle, the Government did not recognize a great responsibility towards education, and the municipality of Freetown did not then feel a civic urge to develop or even maintain the College. Consequently the College was hard put to maintain itself; but it persevered with an average of twenty students until the end of the Second World War.

The first 'science' lecturer was appointed in 1924 and the foundation stone of a small block for science teaching was laid in 1925. From that time the establishment of the College has included a 'science' lecturer. This development was inspired and made possible by the bequests of two Africans: Dr. Obadiah Johnson and Dr. John Randall. It would seem that from 1929 the science lecturer was occupied with a few lectures given to the arts students, and with the non-graduate teacher training course which started in that year. In 1939 a course leading to the Durham Higher School Certificate was started with the hope that this would develop into a Faculty of Science. In 1941 the first students passed in botany, chemistry, physics and zoology—the teaching in all these four subjects being done by one lecturer.

On the outbreak of the Second World War the College buildings were requisitioned by the military authorities, and teaching continued in huts. In 1942 the College moved to Mabang in the Sierra Leone Protectorate some forty miles from Freetown. Here conditions were very primitive, science work proved impossible, and the science lecturer transferred to Government service and started the first formal sixth-form course in science at the Government Secondary School, Freetown. This lecturer was Dr. E. Downing, who eventually left Sierra Leone in 1946, but who returned in 1954 as head of the Department of Chemistry and dean of the Faculty of Science.

In 1945 a Commission to investigate higher education in West Africa, under the chairmanship of Sir Walter Elliott, visited the British West African Colonies, and as a result of this report, University Colleges and Colleges of Arts, Science and Technology were set up in Nigeria and the Gold Coast. When the Commission visited Mabang, economic conditions there were so difficult and the number of staff and students so reduced that they were not impressed and felt that the College was an uneconomic proposition and should be disbanded. This view was vigorously fought by two members of the Commission, Dr. E. H. Taylor-Cummings of Freetown and Sir James Duff, warden of the Durham Colleges. As a result of lengthy negotiations, a new ordinance was published in 1950 in which a largely autonomous College was set up, governed by a Council representative of Government, the Missions, the College teaching staff and other local interests. Financial responsibility was taken over by the Sierra Leone Government, which had the advice of the Council for Overseas Colleges of Arts, Science and Technology. The courses in the College were restricted to those already

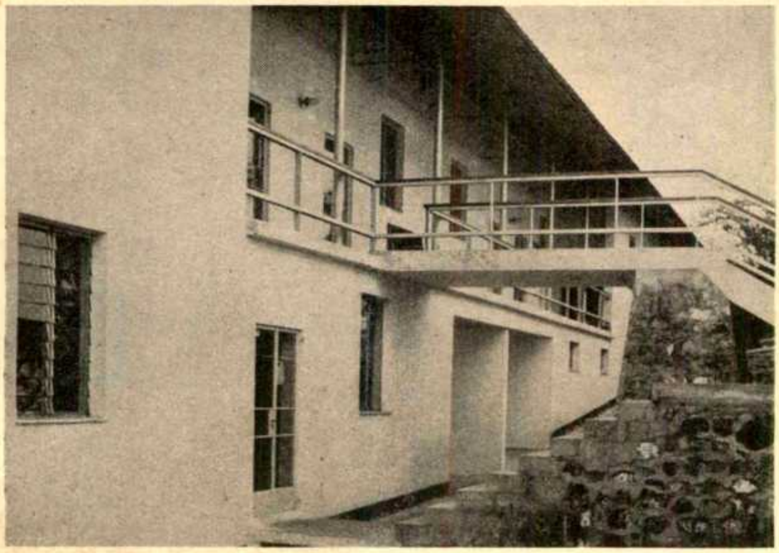

Fig. 2. The new building housing the Department of Zoology and part of the Department of Botany (Photo: T. Lloyd)

existing, namely theology, arts and economics as degree courses, a postgraduate diploma in education, a nongraduate teacher-training course, and science courses to General Certificate of Education (advanced level).

An Education Commission under the chairmanship of Mr. John Fulton (then vice-chancellor of the University of Wales) visited Sierra Leone in 1954 to inquire into the general educational needs of the country and to make recommendations for a long-term policy for the development of Fourah Bay College. In spite of restrictions, the College had grown in numbers. As a result of this the Commission suggested an expansion in the fields of pure and applied science and the goal of university status as an ultimate objective.

A further Commission under Dr. C. H. Wilson, vice-chancellor of the University of Leicester, reported in 1959, and in accordance with the recommendations of this Commission a request was submitted that the College be granted a Royal Charter incorporating it as the University College of Sierra Leone, and the Inter-University Council took over from the Council for Overseas Colleges of Arts, Science and Technology. At the same time the College's responsibility for non-graduate teacher training was transferred to a new and separate Teacher Training College. Now the College consists of Faculties of Arts, Economics, Theology, Pure Science and Applied Science, as well as a postgraduate Education Department and an Extra-Mural Department.

In 1946 the College had returned to Freetown from Mabang and exchanged its old site (where the Queen Elizabeth II Quay was built) for an old military hospital on Mount Aureol, a considerable area of plateau and hillside. The accommodation on this site was either in old stone buildings or temporary wooden structures. With the aid of grants from the Colonial Development and Welfare Fund, the Sierra Leone Government, and local firms, especially the Sierra Leone Development Co., new buildings designed by Mr. Frank Rutter are slowly replacing the old. One of the first priorities in the rebuilding has been new buildings for the science departments, and most of these are now completed (Fig. 2).

In 1955 there was one lecturer in each of the subjects of biology, chemistry and physics, and a teacher of general science, who ran a preliminary course with which to feed the science course. The Faculty of Science was then established containing the Departments of Botany, Chemistry, Geography, Mathematics, Physics and Zoology. Now each of these has a staff of three with the exceptions of Geography (two) and Mathematics (five). At the same time a Department of Applied Science was established, where students take a diploma in engineering, which was established after consultations with the Departments of Engineering, King's College, Newcastle. More recently the preliminary course in general science was discontinued, as the number of students who have taken sixth form science has increased.

Science teaching is concentrated now on the general B.Sc. degree of the University of Durham. The immediate developments envisaged are the consolidation of the present courses and departments, and the addition of honours degrees.

At the moment there are some 350 students registered in the College. As the College is fully residential, the number of students is at present regulated by hostel accommodation, though this is being increased in the near future. Students from Sierra Leone are given preference in acceptance, provided they are suitably qualified. At the moment about half the student body is Sierra Leonian, with a few students from Ghana and Gambia, and the rest from Nigeria. This large Nigerian population is in part a reflexion of the traditional association of that country with Fourah Bay College when the College was the only institution providing a university education in West Africa.

In the science departments a number of research projects are under way, most of them dealing with local conditions.

The biological departments have a wealth of material literally at their doorsteps—a forest reserve only 50 yd. from the Botany Department is being established. Research in the Botany Department under Dr. F. J. Taylor is being directed towards the physiology of the local flora and of freshwater algae, experimental taxonomy of the local flora, the ecology of soil fungi, and the ecology and microbiology of mangrove swamps. The head of the Zoology Department, Mr. J. Phipps, has been studying the local grasshoppers intensively, and other research in that Department includes the study of mud wasps with their spider food, and the nitrogen metabolism of stick insects. The Botany and Zoology Departments have recently established a Marine Biology Laboratory on the coast some eight miles from the College.

The Chemistry Department, under Dr. E. Downing, is interested in the chemistry of natural products, immediately in waxes and their component acid and alcohols. Future lines of development in this Department are likely to be influenced by the parent University.

The two main lines of research being established in the Physics Department (head of the Department, Mr. E. G. Dunstan) are the study of the Earth's magnetic field, which has developed out of studies carried out in Nigeria during the International Geophysical Year, and the study of atmospheric electricity, for which the tropics are especially suited.

In the Geography Department, under Mr. G. Dalton, the main topics of study at present are climatology and land-use surveys. A somewhat related topic under study in the Department of Applied Science, with Mr. B. Pesood, is the nature of lateritic soils, especially with regard to the application of cement stabilization techniques.

The conferment of university college status leads to the hope that Fourah Bay College will attract research workers in science wishing to work in the tropics. From the point of view of the biological field worker, for example, Freetown offers a unique annual rainfall regime on the coast of West Africa, and a range of varied habitats within relatively easy reach.

OBITUARIES

Academician I. V. Kurchatov

The death of I. V. Kurchatov on February 7 is a severe loss to physics, particularly in the U.S.S.R. As director of the Atomic Energy Institute of the Academy of Sciences and an outstanding leader in atomic energy research of all varieties, he played a leading part in determining Russian atomic energy policy. Much credit must go to him for the rapid post-war developments of the Russian programme, and he received many honours from the Soviet Government for his work. He was a member of the Praesidium of the Academy of Sciences and a deputy to the Supreme Soviet of the U.S.S.R.

Born in 1903 in Eastern Russia, Igor Vasilevitch Kurchatov graduated at the University of the Crimea in 1923 and started research at the Leningrad Physico-Technical Institute, then under the direction of A. Joffe, in 1925. Up to 1933 he carried out experimental and theoretical studies of dielectrics, particularly on the properties of Rochelle salt. He was the first to give a mathematical theory of ferro-electricity, basing his approach on the Langevin–Weiss theory of ferromagnetism. His many researches on this subject were summarized in a short book published in 1933. Other work at this time included studies of dielectric breakdown.

Kurchatov's nuclear physics work began in 1933, and in 1938 he was made director of nuclear physics research at the Leningrad Institute, where he and his collaborators conducted many pioneer researches into nuclear reactions produced by neutrons. His work on the activities induced in bromine, together with the results obtained by Fermi's group, led to the first identification of a long-lived nuclear isomer. Other work included detailed studies of the $^{10}B(n,\alpha)$ reaction, and the scattering and absorption of neutrons in water, paraffin and other moderating media. His group was thus exceptionally well placed to follow up the discovery of nuclear fission in 1939, and in 1941 he published an authoritative paper surveying various possible ways of developing a chain-reacting system based on thermal neutron fission of heavy elements.

The Atomic Energy Institute was started towards the end of the Second World War. It is a large establishment, occupying several hundred acres on the outskirts of Moscow, devoted to fundamental research on atomic energy. The wide scope of research there was revealed at the first Geneva Conference on the Peaceful Uses of Atomic Energy in 1955. From his public statement in 1958 claiming Russian priority in the development of a practical military form of the hydrogen bomb, it appears that Kurchatov played a leading part in military as well as civil applications of atomic energy.

In recent years, the problems of plasma physics and controlled thermonuclear reactions formed a significant part of the work at Kurchatov's institute. Studies of magnetic confinement of plasma were vigorously pursued there by a group led by a pre-war Leningrad colleague, L. A. Artsimovitch. The first public account of this work was given by Kurchatov at Harwell in May 1956, in a lecture remarkable not only for its content but also for the bizarre circumstance that his audience was at that time keeping work in this field secret. In 1958 he gave the first account of further work in his institute on this subject, including the building of the enormous magnetic trap installation *Ogra*.

Kurchatov's career is largely synonymous with the development of atomic energy in the U.S.S.R., and although he died before many important aspects have come to fruition, the Russian achievements in this field, together with the size and vitality of his research institute, stand as an impressive testimony to his abilities. He believed in the value of international collaboration in science, and gave a most friendly reception to visitors from England to his institute.

His high scientific abilities, integrity and personal charm greatly impressed all who met him.

R. S. Pease
B. F. J. Schonland

Prof. H. G. Robinson, C.B.E.

Henry Goland Robinson, first professor of agriculture in the University of Nottingham, for many years principal of the Midland Agricultural College and later director of the University of Nottingham School of Agriculture, died on February 20 at his home in Wellington, Shropshire, aged sixty-three. A graduate of the University of Durham, he held appointments at Cockle Park and the then University College of Reading, before becoming senior lecturer in agriculture at the Midland Agricultural College, Sutton Bonington, in 1925. Ten years later he was appointed principal of the Midland Agricultural College, and led the developments which culminated in its union with the then University College of Nottingham as the Faculty of Agriculture and Horticulture. Robinson became the first professor of agriculture and dean of the Faculty.

Robinson will long be remembered for his work for the Midland Agricultural College and the University of Nottingham School of Agriculture, and for his services to agricultural education and farming in Britain, for at one time he was a member of thirty-nine committees, including the Nottinghamshire War Agricultural Executive Committee and several of its sub-committees. He lectured on aspects of agriculture throughout Britain and was a keen advocate of good husbandry. For his services to agricultural education he was appointed a Commander of the Order of the British Empire in 1955, and he was elected emeritus professor of agriculture in the University of Nottingham on his retirement, through illness, in 1954. J. D. IVINS

NEWS and VIEWS

First Award of the Vetlesen Prize: Prof. Maurice Ewing

DR. MAURICE EWING, director of the Lamont Geological Observatory, Columbia University, New York, has been awarded the Vetlesen Prize for outstanding achievement in the earth sciences. This is the first award of this Prize, which consists of a gold medal, 25,000 dollars and support of publication of the recipient's scientific papers. Dr. Ewing, professor of geology at Columbia, and a native of Lockney, Texas, is known internationally for his work in the Earth sciences, and among the previous honours he has received are the Day Medal of the Geological Society of America; the Agassiz Medal of the U.S. National Academy of Sciences; and the William Bowie Medal of the American Geophysical Union. Dr. Ewing, who has been a teacher of both physics and geology, considers himself primarily a physicist who applies fundamental science—physics, chemistry and mathematics—to the study of the Earth.

The Vetlesen Prize was established this year at Columbia University by the G. Unger Vetlesen Foundation for "achievement resulting in a clearer understanding of the earth, its history or its relation to the universe". Like the Nobel Prizes established more than fifty years ago, the Vetlesen Prize recognizes no national boundaries, and any person in any country may be nominated for it. The Nobel Prizes, set up when the Earth sciences were of secondary importance, cover the fields of physics, chemistry, medicine, literature and peace. Funds for both prizes have been provided by Scandinavians. Alfred B. Nobel was a Swedish munitions maker. Georg Unger Vetlesen, a shipping executive, was a native of Norway who became a United States citizen during the Second World War. He established the foundation bearing his name shortly before his death in 1955. The Vetlesen Prize is to be awarded every two years provided a worthy candidate is presented.

The British Museum (Natural History): Sir Gavin de Beer, F.R.S.

THE retirement of Sir Gavin de Beer from the directorship of the British Museum (Natural History) at the end of April this year ends one of the most memorable decades in the history of this institution. He took office at a time when the Museum was still suffering from the effects of the War and during his tenure has succeeded in carrying out an ambitious programme of reconstruction and extension of the Museum facilities and also helped to restore its international prestige. The building of the North Block, with Lecture Theatre, Map Room, General Library and Reading Room, is one of the more obvious additions; but the Mammal Building, extension of the Whale Hall, completion of the Entomological Block, and the new Botanical Gallery, with Cryptogamic Herbarium and laboratories, have all greatly increased the amenities and facilities for scientific study. The Mammal Balconies now include exhibits on the functional morphology of mammals, and the Central Hall has been re-organized to accommodate the big pachyderms and a completely new set of exhibits on evolution which were specially prepared in connexion with the Darwin-Wallace Centenary.

Sir Gavin has carried out investigations on *Archaeopteryx*, and the evolution of Ratites, apart from many historical studies of special interest to the Museum, including the Darwin manuscripts and note-books; Sir Hans Sloane and the British Museum; the Banks correspondence; and he initiated the Historical Series in the Museum Bulletin. Among his other publications a "Short Guide to the Museum", "Scientific Research in the Museum", and a "Handbook to Evolution" were issued for the use of visitors. It was a fortunate coincidence that the Darwin–Wallace Centenary should have occurred during the term of office of one of the greatest authorities on evolution and he took a leading part in the celebrations of that event. In addition, Sir Gavin was president of the fifteenth International Congress of Zoology, held in London during 1958, which attracted by far the largest attendance on record. He was also president of Section D (Zoology) at the meeting of the British Association in Oxford in 1954.

Sir Gavin de Beer's successor will be Dr. T. C. S. Morrison-Scott, director of the Science Museum. Dr. Morrison-Scott was formerly on the staff of the British Museum (Natural History), where he worked mainly in the Mammal Department (see *Nature*, 177, 1061; 1956).

Laboratory of the Government Chemist: Mr. E. H. Nurse, C.B.E.

ON March 31, Mr. E. H. Nurse will retire as acting Government Chemist from what was until recently the Department of the Government Chemist. Mr. Nurse has spent the whole of his career in this Department, which he joined in 1915, following graduation with first-class honours in chemistry from the University of London. During the First World War he served for two years with the Royal Naval Air Service and the Royal Air Force as a hydrogen officer with airships. On the re-organization of the Scientific Civil Service in 1946 he became a principal scientific officer, and he was promoted to the grade of senior principal scientific officer in 1948. He has represented the Department on a number of scientific and technical committees and has been particularly concerned, both at headquarters and the subsidiary laboratories maintained at certain ports, with chemical work in connexion with revenue duties of Customs and Excise. He was appointed Deputy Government Chemist in 1954 on the retirement of Dr. J. R. Nicholls, and on the death of Dr. G. M. Bennett, in February 1959, he became acting Government Chemist. During his period as head of the

Laboratory he has seen its transfer from the Treasury to the Department of Scientific and Industrial Research. He was created C.B.E. in 1958.

Dr. D. T. Lewis

Dr. D. T. Lewis, who has been appointed Government Chemist, was born in Breconshire in 1909 and graduated at the University College of Aberystwyth with first-class honours in chemistry in 1930. He afterwards gained the degrees of Ph.D., and D.Sc., of the University of Wales. Prior to the War, he occupied various teaching posts and held lectureships at the University Colleges of Aberystwyth and Cardiff. In 1941, Dr. Lewis joined the Armaments Research Establishment of the Ministry of Supply and was associated with research and development work on conventional armaments. Leaving this work he was appointed one of the early members of Sir William Penney's atomic weapons team, and for the past seven years he has held the post of senior superintendent of the Chemistry Division at the Atomic Weapons Research Establishment, Aldermaston. In addition to his duties at Aldermaston he has also taken part in overseas trials in Australia and at Christmas Island. He has published a large number of papers in the various scientific journals dealing with inorganic physical and analytical chemistry. He has also published "Ultimate Particles of Matter", a book designed as an introduction for laymen to nuclear and associated sciences. Dr. Lewis is chairman of the Thames Valley Section of the Royal Institute of Chemistry and has been a representative of the Atomic Energy Authority on the board of governors of the Newbury Technical College.

Lucas Heights Research Establishment, Australia:
Dr. G. C. J. Dalton

Dr. George Clifford James Dalton has been appointed director of the Lucas Heights Research Establishment of the Australian Atomic Energy Commission. Dr. Dalton was born at Te Awamutu, New Zealand, in 1916 and was a Rhodes Scholar in 1936. From Oxford he went to the Royal Air Force where he was occupied with radar research. At the end of the Second World War he went to Harwell, where he was in charge of the Fast Reactor Group of the United Kingdom Atomic Energy Authority. This Group carried out the early scientific work which led to the decision to construct the fast breeder reactor at Dounreay. During 1949–55, he was professor of mechanical engineering at Auckland University, New Zealand. Dr. Dalton joined the staff of the Australian Atomic Energy Commission in 1955 as chief engineer and deputy chief scientist.

Second Nuclear Reactor for Lucas Heights

A second nuclear reactor is being installed at Lucas Heights by the Australian Atomic Energy Commission. In announcing this, the Minister for National Development, Senator Spooner, explained that it will be a small and simple apparatus by comparison with the Commission's first reactor, *Hifar* (see *Nature*, 181, 1433; 1958). It will be used in the Commission's general programme for the development of a high-temperature gas-cooled reactor and will be complementary to *Hifar*, which was a 10,000-kW. materials testing reactor used also for making radioisotopes. Production of isotopes, which has already begun, forms an important part of the Lucas Heights programme. The new reactor will produce 10 kW. and will be employed for many tests and measurements where the intense radiation of *Hifar* is unnecessary. These will include physics studies of reactor material, and sample cores (fuel assemblies) for future power-reactor systems. Because of its simplicity and inherent safety of operation, the new reactor will also be used for training staff who will eventually work on other reactors. It is expected that the cost of installing the new reactor and its associated facilities will be in the region of £65,000.

The Game Research Association

A national organization to be known as the Game Research Association has been formed, by a responsible group of farmers, landowners and others interested in game conservation, to promote game research in Britain. The Association will be financed entirely by donations and membership subscriptions, and will carry out research into all factors controlling the game population of the country. The subjects to be studied, as funds and staff become available, include ecology of partridges and pheasants in relation to agriculture, forestry and other land use, regarding game as a natural resource; and also the more immediate problems of game mortality such as gapeworm, the effects of toxic chemicals and effective re-stocking methods. Laboratories for a temporary research headquarters are being loaned by Imperial Chemical Industries, Ltd., at Fordingbridge. The president of the Association is Mr. Harold Macmillan, and vice-presidents, Sir John Ruggles-Brise and Major John Morrison; chairman of council, Lord Porchester. Mr. A. D. Middleton, director of the Imperial Chemical Industries Game Research Station, Fordingbridge, is honorary research adviser, and Mr. F. O. G. Lloyd is honorary secretary–treasurer (temporary London office at 7–8 Great Winchester Street, London, E.C.2).

The I.C.I. Game Research Station, Fordingbridge

The work of this Station at Fordingbridge, in Hampshire, will continue, but with some reduction in the research projects and more emphasis on advisory and educational work. Research will include methods of artificial propagation and population dynamics. The advisory staff will continue, through personal visits, literature and other means, to give practical application to the knowledge which has been gained during fourteen years of work at Fordingbridge and, in pre-war years, in Hertfordshire and other places. Naturally, Imperial Chemical Industries, Ltd., welcomes the formation of an independent Game Research Association, which should be able to expand research in this field. The Fordingbridge team will collaborate in every possible way in the work of the Association.

Research on Grouse

In addition to the Game Research Association, and the work of the Imperial Chemical Industries Game Research Station, a third research project, concerning grouse, is now firmly established. The ecological study of grouse in Scotland, under the direction of Prof. V. C. Wynne-Edwards, of the University of Aberdeen, financed for the past three years by the Scottish Landowners Federation, is now being taken over and expanded by the Nature Conservancy. This is to be part of a wider project known as the Unit of Grouse and Moorland Ecology, the first of such units to be operated by the Conservancy. Its research results, from a long-term study of grouse population dynamics, will inevitably be of permanent value to grouse management, which is an important feature of moorland economics.

State Aid for Museums and Art Galleries of Britain

FOR many years the Museums Association, through a succession of presidents and other officials, has emphasized the desirability—indeed the absolute necessity—of giving some measure of financial assistance to museums and art galleries, especially to the smaller provincial institutions. On February 26, Sir Edward Boyle, Financial Secretary to the Treasury, made a statement in the House of Commons which indicates that H.M. Government is at last fully alive to the present needs of museums and art galleries. There was a practical result in that various grants were announced. First was the direct provision in the Estimates for the national collections, which is to show an increase of £350,000 or 13 per cent. This welcome news will allow the British Museum to appoint fifty extra staff and enable the authorities to keep the Reading Room open to a later hour on, say, two evenings a week. Until 1959 the Victoria and Albert Museum, by means of its Circulation Department, was enabled through a Treasury Grant to disperse the hopelessly inadequate amount of £2,000 per annum to local museums for the purchase of specimens. Last year this sum was increased to £15,000, and now it is announced that the amount has been raised to £25,000. From the professional point of view, it was especially welcome news that the Minister of Education has decided to ask Parliament to approve of an entirely new type of grant to the Victoria and Albert Museum for the benefit of a provincial gallery. By this means it will be possible for Liverpool to purchase the "Holy Family" by Rubens.

It has been continually urged by the Government that the museum problem should be settled locally, and to this end the South Western Museum Regional Council was formed in January 1959. Its aim was to promote closer co-operation between museums, to improve the technical facilities available and to distribute financial assistance to museums and art galleries within the region. It was hoped that the Financial Secretary would be able to make a definite statement regarding assistance to this regional scheme, especially in view of the strong support given only the day before in a memorandum by the Association of Municipal Corporations. Unfortunately he was not able to announce any grant in this connexion. But perhaps the most welcome result of the debate in the House was the statement that the Government now realizes that many museums and art galleries in Britain are inadequately provided for, and that a general inquiry would serve a useful purpose. To this end the Chancellor of the Exchequer has invited the Standing Commission on Museums and Art Galleries to consult the Museums Association and others to consider the desirability of a complete review of provincial museums and art galleries. It is to be hoped that this review will take place in the foreseeable future.

Employment of Scientists in the United States

A REPORT issued by the National Science Foundation gives final information on about 116,000 employed scientists (out of about 127,000) in the National Register of Scientific and Technical Personnel for 1954–55, roughly half of all American scientists at the time (American Science Manpower: Employment and Other Characteristics, 1954–55. Pp. vi+48. (N.S.F. 59-39.) Washington, D.C.: National Science Foundation, 1959). The largest group (41,000) was employed in chemistry and chemical engineering. About half of the 116,000 were employed in private industry and nearly one third by educational institutions. About 50,000 (44 per cent) were engaged in research, development or field exploration, about 20,000 in management or administration and about the same number in teaching. Nearly 40 per cent of the scientists held a doctorate and more than 33 per cent a master's degree. In 1954–55 the median annual salary for scientists reporting this item was 6,525 dollars and, in general, salaries were highest for scientists with a doctorate and those employed in private industry. About 8,000 (about 7 per cent) of the scientists were women, who were employed chiefly in the biological sciences, chemistry and psychology. Of the 127,000 respondents in the 1954–55 Register, more than 90 per cent were civilian scientists employed in scientific or in non-scientific specialities, including education, social work, and humanities. Of the remainder, about 4,000 were on active military duty, 4,200 students, 700 unemployed and 2,000 retired. These groups are not covered in the report.

U.K. Government Relief for Scientific Societies

THE annual report for 1959 of the Parliamentary and Scientific Committee, besides a concise summary of the addresses and discussions during the year, records that the Committee's Rating Sub-Committee welcomed the recommendations of the Pritchard Committee insofar as they offer a 50 per cent rate relief to scientific societies and similar bodies, and extends to industrial research associations the same degree of rating relief as applies to industry in general (pp. 28. London: Parliamentary and Scientific Committee, 1960). Subject to certain reservations, the Committee hopes that the necessary legislation will be introduced by the Government at the earliest possible opportunity. First, the Committee regrets that the Pritchard Committee's recommendations, if implemented, will impose a material rate burden on those scientific organizations which have obtained total exemption under the Scientific Societies Act, 1843, and will also debar from such full relief other scientific societies which might have been able to qualify for exemption under that Act at some future date. The Committee recommended accordingly that if the Government did not find it possible to enable scientific societies to continue to enjoy full rating relief, arrangements should be made by the Minister for Science to afford assistance to scientific societies which will be rendered less effective by the implementation of the Pritchard Committee recommendations. Secondly, the Committee submits that certain modifications in the precise recommendations of the Pritchard Committee will be necessary to ensure that some scientific societies are not debarred from the rating relief recommended by reason of the definition of what is to constitute a charity for the purpose of rating benefit.

Vegetable Research

THE Research Station at Wellesbourne, with its sub-station at Paglesham, Essex, was established in 1949 and has now a considerable volume of results (Ninth Annual Report, 1958, of the National Vegetable Research Station, Wellesbourne, Warwick. Pp. 55. 1959). A long-term assessment of chemical, physical, biological and ecological changes involved in raising soil fertility to the high level required for vegetable production shows that farmyard manure exerts the greatest single effect. For some crops, however, the greatest yield is only obtained by supplementing with fertilizer. More detailed chemical investigations showed that there was an accumulation of sucrose, fructose and glucose, and a decrease in phosphorylated intermediaries, in the roots of beet immediately before flowering.

The report describes many studies on competition between weeds and crop, and the effects of pre-planting treatments. Various agents for weed control are under investigation, but it is interesting to note that the mere fact of growing vegetables for three years has reduced the number of weed seeds in the soil to about one-sixth the original number. Studies on the control of environmental conditions include extensive work on irrigation, and lettuce particularly benefited from adequate watering through its period of growth. Disease studies are now extensive, but perhaps the most significant findings are that silvering disease of beet can be controlled by seed treatment with streptomycin, the effectiveness of aldrin in reducing club-root disease, and the use of zinc frit for the control of powdery mildew of turnips and cabbage. Entomological investigations are concerned mainly with cabbage root fly, carrot fly and the root aphid of lettuce, while in methods of control, seed treatment and soil incorporation figure largely. Plant breeding is perhaps slow to give immediate results, but the report shows useful progress with many vegetables ; in this, as indeed in other sections, reference must be made to the report itself, and it is clear that as the years go by it will become more and more valuable.

Plasma Physics and Thermonuclear Research

The new section, Part *C*, of the *Journal of Nuclear Energy* is to be published quarterly and is devoted to plasma physics, accelerators and thermonuclear research (Pergamon Press, 4–5 Fitzroy Square, London, W.1). As Sir George Thomson explains in his brief foreword to the first issue (1, Nos. 1/2, October 1959), plasma physics is part of that study of gaseous discharges to which physics owes the fundamental discoveries of electrons and of isotopes, and from which it is hoped to be able to solve the problem of obtaining controlled energy from fusion reactions between nuclei of isotopes of hydrogen. Prof. M. S. Livingston in his foreword explains that accelerator technology has contributed significantly to the newer technology of thermonuclear science, and therefore the new journal will perform an important and useful function in sponsoring the merger of the two technologies with the study of plasma physics. In addition to eight original contributions, the October issue contains abstracts in English, prepared by the U.S. Atomic Energy Commission, of articles from "The Physics of Plasmas", published by the U.S.S.R. Academy of Sciences, a collection divided into four volumes in which are described the theoretical and experimental investigations carried out during 1951–58 in the Institute of Atomic Energy of the U.S.S.R. Academy on controlled thermonuclear reaction and associated subjects. Other features of the issue are translations of articles from *Atomnaya Energiya* and a list of titles of current papers and reports on plasma physics, accelerators and thermonuclear research appearing in some 50–100 journals published throughout the world. The October list covers publications since January 1, 1959. The editor-in-chief of Part *C* is Dr. J. V. Dunworth.

Russian Chemical Journals

The Chemical Society announces that cover-to-cover translations of two additional Russian chemical journals are to be published with the assistance of the Department of Scientific and Industrial Research. The *Russian Journal of Physical Chemistry* (*Zhurnal Fizicheskoi Khimii*) is being published by the Society in translation starting with the issue for July 1959. It is intended that subsequent monthly issues will appear regularly, and it is hoped that the interval between the receipt of the Russian original and the publication of the translation will eventually be reduced to about three months. Mr. R. P. Bell is scientific editor of the translation. Another journal, *Uspekhi Khimii*, will be published monthly in translation under the title *Russian Chemical Reviews*, starting with the issue for January 1960, which it is hoped to make available in April. The scientific editor of the translation will be Dr. J. N. Agar, assisted by Dr. A. R. Katritzky and Dr. R. H. Prince. Translations for these journals are supplied for the Society by Infosearch, Ltd., and distribution is undertaken by the Cleaver-Hume Press, Ltd. Subscription inquiries should be addressed to the sole distributors, Cleaver-Hume Press, Ltd., 31 Wright's Lane, London, W.8.

The United States National Museum

In a comprehensive report for 1959 it is stated that the site near the Washington Monument is now being prepared for the proposed Museum of History and Technology (The United States National Museum. Annual Report for the year ended June 30, 1959. Pp. vi+178. Washington, D.C.: Government Printing Office, 1959). The policy of this Museum is described as "to illustrate by means of the historic collections in the Smithsonian the cultural and technological development of the Nation since Colonial times". The plans include some thirty-eight major halls which have been coherently related to show a logical sequence of events. The needs of the individual museum visitor have been kept in mind, for it is conservatively estimated that some five million persons will enter the building each year. Provision is made for adequate air conditioning for the protection of objects as well as the comfort of visitors, circuits for television and electronic guide devices, and other electrical and plumbing devices in this great modern display unit. The plans thus indicate a museum building that will for the first time allow the great collections of the Smithsonian to be viewed in an adequate manner. During the sixth year of the continuing modernization programme work has also moved steadily forward on the other two fronts, namely, the renovation of the permanent exhibition halls in existing buildings and assistance to other branches of the Smithsonian Institution in the planning and presentation of exhibits.

Proteins from Grass

Pirie and other scientific workers have directed attention to reserves of protein available in grass and other chlorophyll-containing material normally consumed as animal foodstuffs, but potentially of use to man. The efficient production of good-quality edible protein from such sources depends on the solution of various biochemical engineering problems which have been investigated by the Rothamsted group for some years. A recent report from British Glues and Chemicals, Ltd., reflects the increasing interest in leaf protein; the Chayen impulse process, introduced a few years ago by this firm for the disintegration and extraction of bones and animal fats, has now been applied to a variety of other materials, including oilseeds, such as groundnuts, and grasses. The principle of this method lies in the use of shock waves of sufficient intensity and frequency to burst the tissues and cells of biological materials; it is illustrated by the depth-charge technique used in anti-submarine warfare and by the method of fishing with the aid of a dynamite charge. The report states that 100 tons of fresh grass (of 80 per cent water content) treated by the Chayen method yields about 2¼ tons of edible protein together with two important by-products—7 tons of fibre (suitable for the production of hardboard) and 0·6 tons of a 'chlorophyll syrup' containing fat-soluble vitamins, pigments and steroids. The commercial development of this process will be watched with interest by all who are concerned in any way with the nutritional problems of tropical and other areas, and it is to be hoped that the method can be introduced into those regions where additional supplies of supplementary protein are most needed.

Department of Scientific and Industrial Research: Studentships and Fellowships

THE Department of Scientific and Industrial Research, which this year has awarded studentships to 2,143 research workers, as well as 271 advanced course studentships and 48 research fellowships, at a cost expected to exceed £1 million, and grants totalling £2,238,000 to 287 investigators at universities, technical colleges and similar institutions for researches in the natural and human sciences and technology, has now issued two publications replacing the former "Notes on D.S.I.R. Grants to Graduate Students and Research Workers". "D.S.I.R. Studentships and Fellowships" describes in detail the different types of studentships and fellowships in science and technology offered by the Department, including those tenable abroad and also the science studentships and fellowships administered on behalf of the North Atlantic Council (pp. 24. 1*s*. 6*d*. net. D.S.I.R. Research Grants. Pp. iv+10. 1*s*. 3*d*. net. London: H.M. Stationery Office, 1960). "D.S.I.R. Research Grants" gives similar information about the grants for special researches awarded by the Department and includes a note on the scheme of Senior Visiting Fellowships instituted by the Organization for European Economic Co-operation which the Department operates.

Gassiot Research Fellowships in the Meteorological Office

THE official list of the functions of the Meteorological Office includes "Research in Meteorology and Geophysics". In the long history of the Office, 'geophysics' has come to mean terrestrial magnetism and seismology, and continuous observations in these fields have been made for many years at Kew, Eskdalemuir and Lerwick. In the past two decades the demands of meteorology have been such that it has not been possible to do much more than to maintain and publish the observations, especially in seismology. It has long been recognized that this is not a desirable state of affairs, and an important step towards the revival of research in the Meteorological Office in both fields has now been taken by the creation by the Secretary of State for Air of two research fellowships (named after John P. Gassiot, F.R.S., who in 1871 bequeathed to the Royal Society a large sum of money for the maintenance of magnetical and meteorological observations at Kew) in geomagnetism and seismology, respectively. The fellowships, which are tenable for seven years with a possible extension to ten years, will allow the holders to pursue any studies falling within the acknowledged fields of the two disciplines, with the aid of facilities provided by the Meteorological Office. It is also intended that there will be close contact with universities. Selection of the Fellows will be made in association with the Royal Society.

Gift to the Rensselaer Polytechnic Institute

A GIFT of one million dollars has been pledged to the Rensselaer Polytechnic Institute by Mr. and Mrs. Erik Jonsson, of Dallas, Texas, through the Jonsson Foundation, to help finance a new Science Centre at Rensselaer. Mr. Jonsson is chairman of the board of Texas Instruments, Inc. The gift, one of the largest single grants recently received by the Institute, is for construction of one unit of the Science Centre on the Rensselaer campus.

University News: Birmingham

UNDER the policy of general expansion throughout the University of Birmingham, it is now announced that the Faculty of Commerce and Social Science will be accommodated in a completely new building, and plans are in preparation with the view of commencing building work in 1961 and completing it in July 1962. Work on the £1 million building for the Department of Biology will start in mid-1960 and will be fully completed by 1963.

Dr. J. T. Davies, lecturer in chemical engineering in the University of Cambridge, has been appointed to the chair of chemical engineering and to the headship of the Department of Chemical Engineering from October 1, 1960. The following appointments have also been made: Dr. Gillian Vaisey, to be lecturer in the Department of Civil Engineering; G. Lees, to be lecturer in road materials in the Department of Civil Engineering; D. R. Milner, to be Lucas Fellow in metal joining in the Department of Industrial Metallurgy. A readership in reactor physics has been conferred on Dr. J. Walker, senior lecturer in physics, and in social medicine on Dr. C. R. Lowe, senior lecturer in social medicine.

Leeds

APPOINTMENTS to professorships are announced as follows: Dr. J. Nutting, as professor of metallurgy from a date to be arranged; Mr. D. R. Wood, as professor of pharmacology from September 1; and Mr. J. M. Cameron, as professor of philosophy. Major grants to the University are: by the Department of Scientific and Industrial Research, £40,000 to the Department of Physics for research on cosmic ray showers, £5,650 to the Department of Leather Industries, and £2,200 to the Department of Electrical Engineering; by the Ministry of Aviation, £2,000 to the Houldsworth School of Applied Science for research on the fatigue properties of ferrous and non-ferrous alloys; by Imperial Chemical Industries, Ltd., £1,500 to the Department of Inorganic and Structural Chemistry to support X-ray structure analysis; and by the Hickson's Timber Impregnation Co. (G.B.), Ltd., £1,000 to provide a fellowship in the Department of Botany.

South Africa and Commonwealth Scholarships

MR. I. F. A. DE VILLIERS, First Secretary in the Office of the High Commissioner in London for the Union of South Africa, writes: "The article in *Nature*, of January 30, p. 271, on 'The Wandering Scholar in the British Commonwealth', mentions references, in debates in both Houses of Parliament, to the non-participation of the Union of South Africa in the Commonwealth Education scheme. I am concerned that this may have conveyed the incorrect impression that South Africa does not intend to participate; the actual position is that while the South African Government was not able to give consideration to the proposals of the Oxford Commonwealth Education Conference until quite recently, it has in fact decided to participate in both the Commonwealth Scholarship Plan and the Commonwealth Education Liaison Committee."

Announcements

PROF. LEO SZILARD, professor of biophysics at the University of Chicago, has been awarded the Albert Einstein Gold Medal and Award for 1960. The Award itself is valued at 5,000 dollars, and is presented annually with the Medal.

THE award of the Birbal Sahni Medal for 1959 has been made to Prof. P. Parija. The award was instituted by the Indian Botanical Society through a grant of Rs. 2,500 made by Prof. T. S. Sadasivan (Madras) in 1957 in memory of the late Prof. Birbal Sahni. The Medal is awarded annually in recognition of services to botany in India.

MR. R. M. WYNNE-EDWARDS, joint managing director of Constructors, John Brown, Ltd., has been appointed chairman of the Building Research and Road Research Boards for the period April 1, 1960–March 31, 1965, in succession to the two present chairmen, Sir Herbert Manzoni and Mr. E. John Powell, who have completed their terms of office.

THE editorial office of *The Biochemical Journal* has moved from the Lister Institute to 133–135 Oxford Street, London, W.1, where all further communications should be sent.

BY the generous benefaction of Prof. R. L. Wain, professor of agricultural chemistry in the University of London (Wye College), an income from the patents on his discoveries in the field of selective herbicides has been made available to the Agricultural Research Council and has been used to establish the Wain Trust Fund. One of the objects of the Fund is to facilitate the interchange of scientists between universities in the United Kingdom and overseas. The Council can now make available annually one to two awards (depending on the sums involved) to members of university staffs in Britain who wish to spend a period abroad. Applications or inquiries should be made to the Secretary, Agricultural Research Council, Cunard Building, Regent Street, London, S.W.1.

THE forty-fourth annual meeting of the Federation of American Societies for Experimental Biology will be held in Chicago during April 11–15. Further information can be obtained from Sidney S. Negus, Medical College of Virginia, Richmond, Virginia.

THE spring meeting of the Photobiology Group will be held at the University of Reading during April 1–2. Further information can be obtained from Dr. D. Vince, Department of Horticulture, University of Reading, at Shinfield Grange, Shinfield, Berks.

THE Department of Chemical Technology of the Bradford Institute of Technology is organizing a symposium on Fluorescence and Fluorescent Compounds on May 6. Further details can be obtained from the Registrar, Institute of Technology, Bradford, 7.

IT is announced that the third international congress in Photobiology is to be held in Copenhagen during July 31–August 5. The last date for registration is April 1, and further information can be obtained from Dr. B. C. Christiansen, Finsen Memorial Hospital, 49 Strand Boulevard, Denmark.

THE eighth conference of the British Agricultural History Society will be held during April 7–9 at Harper Adams Agricultural College, Newport (Salop). Further information can be obtained from the Secretary of the British Agricultural History Society, Department of Agriculture, University of Oxford.

THE Institution of Mining and Metallurgy will hold an international Mineral Processing Congress at Church House, Westminster, London, S.W.1, during April 6–9. Further information can be obtained from the secretary, B. W. Kerrigan, Institution of Mining and Metallurgy, 44 Portland Place, London, W.1.

THE Faraday Society has announced that a general discussion on Oxidation Reduction Reactions in Ionizing Solvents will be held in the University of Durham, King's College, Newcastle upon Tyne, 1, during April 11–13. Further information can be obtained from the Assistant Secretary, Faraday Society, 6 Gray's Inn Square, London, W.C.1.

THE second International Spring School of Physics of the Istituto di Fisica Theorica of the University of Naples will be held during April 20–May 7. The school is sponsored by the Società Italiana di Fisica and the University of Naples, and is to receive a grant-in-aid from Nato. Applications must be sent to the director of the School not later than March 31.

THE sixty-fifth annual congress of the South-Eastern Union of Scientific Societies will be held during April 22–25. Lectures and excursions will be held covering the biology, zoology, geology and archæology of the south-eastern counties; visits to various museums in the region will also be made. Further information can be obtained from F. Edwards, 53 The Drive, Shoreham-by-Sea, Sussex.

THE annual conference of the Ergonomics Research Society will be held in Cambridge during March 28–31. The topics to be discussed include ergonomics in the Armed Forces, in building research and athletics; and ergonomics in the Netherlands. There will be a symposium on factors in prolonged work, especially inspection. Further particulars can be obtained from Mr. D. U. Hunt, British Iron and Steel Research Association, Park Lane, London, W.1.

THE Annual Easter Congress of the Universities Federation for Animal Welfare will be held at Saltley College, Birmingham, during April 8–12. The programme includes a symposium on Humane Experimental Technique and lectures on introducing animal welfare to Libya (Dr. F. Jean Vinter), aspects of meat production (D. Norma Egginton) and humane slaughter (Colonel D. J. Anthony). Further information can be obtained from UFAW (Easter Congress), 7a Lamb's Conduit Passage, London, W.C.1.

DEVELOPMENT OF WOOD-USING INDUSTRIES

UNDOUBTEDLY among the most significant happenings of the past twelve months for the future of forestry and timber in Great Britain has been the publication of two reports on economic studies carried out by a Canadian firm of consulting engineers, Messrs. Sandwell and Co., Ltd., of Vancouver. These reports are entitled "Small Pulp Mill Survey" and "Board Mill Survey", respectively, the former having been conducted under the auspices of the Organization for European Economic Co-operation, the United Kingdom being one of seven member countries studied, while the latter was undertaken for selected regions in Great Britain at the request of the Forestry Commission[*].

There are two reasons why such surveys were called for. First, the wood-pulp industry in Europe is very largely concentrated in Scandinavia, the remaining countries importing either pulp or materials made from it, such as paper or fibreboard; naturally, it was desirable to see if something could be done in the home country to reduce dependence on imports and to develop new industries. Secondly, as a consequence of the extensive afforestation programmes of the past three or four decades, a very large volume of wood is becoming available, mostly from the small trees removed in the thinnings that must be carried out to make it possible for the trees retained in the forest to grow to saw-timber size within a reasonable time. This amount is not only already large, but also is increasing annually—and will continue to do so for a long time yet—while one of its main markets, namely, pit-wood for the coal mines, is approaching saturation; Scotland's needs are already met entirely from Scotland's own forests, and the demand is showing signs of falling off.

Basic to these studies are the facts that Britain imports three-quarters of a million tons of paper and boards out of her annual consumption of 4 million tons (1956 figures), and production in Britain of the balance is dependent on the import of 2 million tons of pulp. Expressed otherwise, three-quarters of the wood that is consumed by the British paper industry is imported.

It has always been recognized that for a pulp mill to be profitable there are several essential requirements which are not easy to fulfil. Only three of these requirements need be mentioned here: (1) a large and regular supply of suitable wood; (2) the cost of that supply delivered at the mill must be low compared with the price that is paid in the existing markets for such material for other uses such as pit-wood, light poles and box-wood; (3) a good water supply with effective means of disposal of effluents.

The consultants have tried to answer two main questions: (1) Given a delivered cost for wood, what is the minimum capacity of a pulp mill to be economically feasible under any of the processes available? (2) If the output is to be as low as 30 tons per diem, at what price must wood be available? It is not possible here to discuss the details; but their findings are that a separate plant set up solely to produce ground-wood (that is, mechanical) pulp is out of the question; that for a chemical (bleached sulphate) pulp plant receiving its raw material at a price that would be viewed as so low as to be doubtfully attainable by United Kingdom growers—though it is the average top price prevailing in North America—namely, £8 10*s*. a ton, the plant would have to be able to turn out at least 80 tons of pulp a day. If its capacity were as low as 30 tons a day, the price that it could afford to pay for the wood would be altogether impossibly low.

The overall conclusion is that if Britain is to develop in this field, her pulp mill must be integrated with other wood-based industries, notably with paper-making, like the recently opened hardwood pulp mill at Chepstow. Integration with saw-milling and connected industries such as veneering, plywood and furniture would also be helpful by providing an appreciable proportion of the raw material from waste available on the spot at a very low cost. If this can be done, a relatively small mill of 30–40 tons capacity should be able to pay a price for the rest of its wood which, though still lower than is currently being obtained, can be viewed as not impossibly so.

It is estimated that by 1965 two centres in Scotland (Inverness and Fort William) would probably be producing enough wood surplus within 100 miles radius by road to support a small-scale pulp mill if it can pay something like the current price for its wood, but probably only ten years later if its price is appreciably lower. At least two other centres are expected to have a similar surplus by 1975. It is known that a proposition to site such a mill in Scotland is under serious consideration by a leading group of wood industrialists. Incidentally, it has to be noted that our paper is mostly made of blended materials, including large amounts of straw—of which much more would be available if needed—and imported pulp of a type that would be selected in relation to the properties of that obtained from the local materials.

The second survey deals with the possible establishment of further hardboard, chipboard and insulating board mills, using the same raw material from the thinnings of our plantations. Although the amount of hardboard we import to-day corresponds to a production of 500 tons per diem, it is concluded that its manufacture would not be economically attractive unless the raw material could be cheapened to an extent that, as for the pulp mill, would only be attainable by integration with other wood industries, and this is not currently a practicable proposition with sawmilling because this industry is at present dispersed among a very large number of relatively small units. It is emphasized that chipboard and insulating board mills also require to be large to be reasonably profitable, with a daily output of at least 50 tons. They would be able to pay a rather higher price for their wood than that quoted for the pulp mill, a price that is still lower than the grower is at present getting, but within the range that he might be able to accept without putting himself out of business, provided every possible economy was made. Capital requirements would be about £1–2 million. In contrast with the prospects of further pulp mills, the most favourable area for board mills is considered to be southern England.

In the light of these surveys, it seems likely that Britain will have new wood-using mills of either or both types being built in the coming decade. There are not a few criticisms of the premises underlying these Sandwell reports with regard to costs, prices and trends, and suggestions that the size for profitability, at least for board mills, could be rather smaller and the capital cost less. However, it seems agreed that there must be a considerable reduction of the costs of growing and delivering the large amounts of wood required, and that there is certainly room for reduction by improved efficiency all along the line; there will be every incentive for cheaper production as other markets are bound to fall during what, without such mills, will be a period of large over-production. In all cases there will be marketing problems, especially in view of the free competition of imports under the Outer Seven trade agreements, but cautious optimism appears justifiable, and expansion in the directions indicated is to be expected in the near future.

BIOCHEMISTRY AT THE IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY, LONDON

THE Imperial College of Science and Technology, London, has accepted a benefaction of £350,000 from the Isaac Wolfson Foundation to build and equip new laboratories for biochemistry and chemical microbiology and to support teaching and research in these subjects. Dr. E. B. Chain has been appointed to the chair of biochemistry and will take up the appointment in 1961.

This munificent benefaction will enable the College to erect a new building, to be known as the Wolfson Laboratory, adjacent to the Royal College of Science building in Imperial Institute Road. The Biochemistry Department will also occupy some laboratories in the Royal College of Science building shortly to be vacated by the Physics Department for its large new building in Prince Consort Road. Biochemistry at the College, which has been under the direction of a reader since the last occupant of the chair, Prof. A. C. Chibnall, succeeded Gowland Hopkins at Cambridge during the War, will thus burgeon out. The Department's new equipment will include fermentation units of comparatively large size and workshops for advanced mechanical and electronic equipment. It will provide accommodation for training and research in the neglected borderland between biochemistry and chemical engineering, and for research on an adequate scale on the biochemical production of chemicals of interest. Such a department, set in the Imperial College, with its very large school of engineering and flourishing schools of physics, organic chemistry and plant physiology, should find conditions highly propitious for major advances in biochemical knowledge.

Dr. Chain has since 1948 been at the Istituto Superiore di Sanità in Rome, where he has built up one of the best equipped, largest and most active centres of biochemical research in Europe. He has had there many of the facilities for which he had earlier, and unsuccessfully, pressed in Great Britain—in particular, equipment of pilot-plant scale for fundamental studies of substances of microbial origin and biochemical interest.

Dr. Chain, a graduate of the University of Berlin, was forced to leave Germany by Nazi persecution in 1933, and he became a British subject in 1939. He first worked under Gowland Hopkins at Cambridge, on snake venoms and phospholipids. In 1935 came an invitation from Prof. (now Sir Howard) Florey to join the scientific staff of the Sir William Dunn School of Pathology at Oxford, with the object of organizing a biochemistry section there. As University lecturer in chemical pathology he remained at Oxford until the end of 1948. His work there included a study of the biochemical mode of action of some snake venoms, on the mode of action of lysozyme, on the mode of action of the spreading factor, on tumour metabolism and on a rapid method for the determination of phosphate. In 1938, with Florey, a systematic study of anti-bacterial substances produced by micro-organisms was started. This led to the discovery of the curative properties of penicillin and heralded the era of antibiotics. In this work he played a leading part in the chemical studies on the isolation and structure of penicillin. For his part in the discovery of penicillin he was awarded the Nobel Prize for Medicine and Physiology in 1945, jointly with Sir Alexander Fleming and Florey. Dr. Chain was elected to fellowship of the Royal Society in 1949.

At the Istituto Superiore di Sanità, with the support of Prof. D. Marotta, director of the Institute, and the Italian Government, Dr. Chain has carried out research in many directions. His collaborators have included chemical, mechanical and electronics engineers, biochemists, organic chemists, microbiologists and geneticists. A wide range of subjects has been studied, mainly in two fields of biochemistry, chemical microbiology and intermediate carbohydrate metabolism in animals, touching on the methodological, biochemical and biological as well as the chemical engineering aspects of the subjects.

Among the biochemical subjects studied in the field of chemical microbiology have been factors involved in the biosynthesis of penicillin. The continuation of this work led to the discovery, by a team of research workers in the Beecham Laboratories in England, to which Dr. Chain has acted as adviser and consultant, that the main part of the penicillin molecule (6-aminopenicillanic acid) could be made by biosynthesis, and that this could be modified afterwards by chemical means. A great range of new antibiotics can be made in this way. They include a penicillin which is acid-stable and can be taken by mouth and one which attacks staphylococci resistant to normal penicillin. Compounds of this kind open up exciting prospects in the antibiotics field.

Other studies conducted in Rome have been on the green iron-containing streptomycete pigment ferriverdin, on submerged kojic acid and citric acid fermentations and on the production of ergot alkaloid in submerged fermentation. Among the chemical engineering aspects of chemical microbiology there have been extensive studies on agitation and aeration. Biological studies have included investigations on the relations between morphology and metabolism in filamentous fungi and genetical problems in filamentous fungi. Studies on carbohydrate metabolism in animals have been concerned with the mode of action of insulin and the interrelations between carbohydrate and amino-acid metabolism in brain and nervous tissues.

DIRECTION OF SCIENTIFIC AND TECHNICAL RESEARCH IN FRANCE

A PUBLICATION, *French Science News* (2, April–June, 1959), published by the Direction Générale des Affaires Culturelles et Techniques for the Ministère des Affaires Étrangères, describes the organization which has been set up to determine policy for scientific and technical research throughout the country. Two high-ranking committees have been formed, the first being an Interministerial Committee, the members of which include the Prime Minister as chairman, the Minister of National Education, the Minister of the Armies, the Minister of Finance and Economic Affairs, the Minister of Industry and Commerce, the Minister of Agriculture, the Minister of Public Health, and qualified representatives of the French community.

The main tasks of the Interministerial Committee, which is responsible for proposing to the Government all measures for the development of scientific and technical research, are as follows:

"To maintain a fair balance between the amount of credits appropriated for the different fields of research;

"To develop to its maximum usefulness French national research, which presupposes a detailed study of the profession of a research specialist and the milieu in which research is performed;

"To anticipate new research possibilities which will benefit the nation, which presupposes long-term government options in the field of science."

The second is an Advisory Committee, the members of which are: Maurice Letort as chairman (Letort is scientific director of Research and Studies, Centre of Charbonnages de France); Prof. Pierre Aigrain, vice-president of the Paris Faculty of Science; Prof. Jean Bernard, Paris Faculty of Medicine; Prof. Rene Dumont, National Agronomic Institute; Prof. Paul Germain, Paris Faculty of Science; Rene Latarjet, co-director of the Radium Institute and the Curie Foundation; Prof. Andre Lichnerowicz, Collège de France; Maurice Ponte, general director of the Compagnie Générale de T.S.F.; Prof. Charles Sadron, Strasbourg Faculty of Science and director of the Centre of Macromolecular Research; Pierre Taranger, industrial director of the French Atomic Energy Commission; and Felix Trombe, research director at the National Scientific Research Centre (Mont-Louis).

The Committees are served by a common secretariat directed by a general delegate. The general delegate can form work committees for specific objects and composed of experts. He works in close co-operation with the general planning commissioner.

The journal is published quarterly by the Association pour la Diffusion de la Pensée Francaise, 23, rue La Perouse, Paris, 16^{e}.

PRODUCTION AND CONSUMPTION OF ENERGY IN GREAT BRITAIN

DURING the past four years some remarkable changes have taken place in the consumption of energy in the United Kingdom. Indeed, since the War the situation in the whole of Western Europe has changed, from that of an energy-exporting economy to that of an energy-importing one. A few years ago there were fears of a shortage of energy in Great Britain. To-day there is the picture of rapidly rising coal stocks, and of real alarm in the mining villages.

Recently this subject was dealt with in an enlightening talk to the Fuel Luncheon Club by Sir Harold Hartley*, whose association with the international study of the energy problems of Western Europe entitle him to be listened to with earnest attention. His revelations should disturb any complacency with regard to the extent of our technological effort in the development of our coal resources.

The pattern of the energy consumption has changed quickly in the following respects in the past four years. Coal consumption fell 3 per cent per annum between 1955 and 1959, while that of oil rose by 12 per cent per annum. Electricity consumption continued its steady annual rise of 6 per cent, while gas declined by 1 per cent per annum. The competitive position depends upon factors of efficiency and of convenience, the relative basic prices of the therm in the primary forms of energy being: coal at the pithead, price 3½*d*., at £10 per ton, 8¼*d*.; fuel oil, at £10 per ton, 6*d*.; paraffin, at £20 per ton, 11*d*.; while gas at the average price costs 1*s*. 9*d*. per therm, and electricity at 1·55*d*. per unit, 3*s*. 9*d*.

---

* Talk to the Fuel Luncheon Club on January 19 on "Energy in the United Kingdon—the Changing Scene", by Sir Harold Hartley.

While stagnant demand has struck the coal-fields, technical advancement has raised the potential productivity of the deep mines to a figure of 3·86 tons per man-shift. This is a pointer to the possibilities of saving the competitive position of coal so far as regards price. The technological aspects offer greater possibilities, if adequately pursued. Thus, in the production of electricity the coal station can compete favourably with the nuclear energy station, because of the greater inherent efficiency that has been developed over recent decades through improvements in technique and design.

The same story of change and advancement could apply to the gas industry, since the technical outlook of the industry has changed radically. It is not likely that the gas industry will build in the future conventional carbonizing plants, for attention is now being turned towards the total gasification of coal, bringing into use new techniques applicable to the use of cheaper low-rank coals. With these there may well be combined processes involving the gasification of oil, and the use of imported liquid methane. With high-pressure gas generation, pipe-line distribution over long distances becomes practicable and economic.

In regard to oil, the question of availability has been changed by the outlook regarding the discovery of new sources of oil in the Middle East, Libya and the Sahara, and of large natural gas fields in the Pyrenees. Against this must be set the likely growth of demand for energy, as the under-developed countries in the world respond to modern standards of living.

Sir Harold Hartley, in considering the energy outlook, has attempted to sketch the future pattern of energy consumption in Britain. Some 280 million tons of coal equivalent will be required per annum by 1965. Of this, some 9¼ million tons may come from nuclear energy, and 8 million tons in coal equivalents from hydro-electricity, coke and oil for generating power, leaving some 55 million tons per annum for steam generation by coal, an increase of some 10 million tons over 1959. The true forecast for the growth of other uses of coal, gas and oil offers a more difficult problem, and may well depend upon the pattern of technological advancement. Gas, provided it can be made at a competitive price, has potentialities in the domestic and industrial sphere, at three different levels of calorific value: a domestic gas at 500 or more B.T.U./cu. ft.; a synthesis or industrial gas of 320 B.T.U.; and a producer gas of 180 B.T.U./cu. ft., for which there are still uses, particularly in specialized fields and where the gas can be used, as in coke production, to free fuels of higher calorific value.

The competitive power of coal and its derived fuels can only be enhanced if the needed technological effort is put into the attempts to develop the new processes needed. Inevitably, the future demand will tend towards requiring energy either through a wire or a pipe, with any question of handling refuse or polluting the atmosphere excluded. Further, in the direction of the total gasification of coal lies the only hope of solving the problem of sulphur pollution.

In the matter of these potential fields of development an adequate tempo of research and development has been sadly lacking. Sir Harold voices the opinion that national policy in regard to research and development in the field of energy is badly out of balance. Very large sums of money and much available scientific effort are devoted to the nuclear field and insufficient of these resources to the utilization of coal, our greatest national asset.

R. J. SARJANT

HOST INFLUENCE ON PARASITE PHYSIOLOGY

THE sixteenth annual conference sponsored by the Bureau of Biological Research was held at Rutgers University, New Brunswick New Jersey, during January 29–30. The subject for discussion was host influence on parasite physiology.

The chair was occupied in turn by Dr. L. A. Stauber (Rutgers University), Dr. Norman Stoll (Rockefeller Institute) and Dr. Wm. Trager (Rockefeller Institute).

In his opening remarks, Dr. T. von Brand (Bethesda) observed that there was a time not very far back when a person interested in parasite physiology was regarded as an oddity. Now a 'physiological bandwagon' was emerging, possibly a reflexion of the brilliant advances being made in biochemistry. The study of parasite physiology, he considered, had changed in many ways; more people were interested and there was an emphasis on instrumentation, which demanded complicated apparatus, although man himself was the chief factor in any research. He recalled that during his youth in Germany, Weinland, that prince of experimenters, had been held up in his work on *Ascaris* metabolism for lack of a reducing valve. Distinct differences were apparent on the lines along which research on free-living invertebrates and parasites had developed. With the former the most significant advances were made by von Frisch in the field of sensory physiology. The study of parasites had developed along more chemical lines, possibly due to the fact that such early workers as Bunge and Weinland were interested primarily in chemical reactions. The biochemistry and physiology of parasites were initiated and extended in seeking to elucidate the mode of action of old or in the search for new drugs. Advances in our knowledge of host–parasite relationships followed. Non-biochemical studies of parasites were, however, of equal importance.

Dr. L. R. Cleveland (University of Georgia) then gave a paper on the effects of insect hormones on the protozoa of *Cryptocercus* and termites. This wood-feeding cockroach *Cryptocercus* has nine families, fourteen genera, and more than thirty species of flagellate parasites in its hind-gut. During each moulting period of a host all these species undergo sexual cycles. In the flagellates of adults and intermoult nymphal hosts, sexuality never occurs under natural conditions; when the insect growth and differentiation hormone, ecdysone, is injected into such hosts, gametogenesis is induced in their flagellates, and the time required for induction depends, within certain limits, on the amount of ecdysone injected. In an adult, 2,000 units will induce it in four genera within 3 hr.; 100 units will do the same in a 4th instar intermoult nymph.

Under natural conditions the sexual cycles of some genera of flagellates require six days, some nine, some twenty-six, and others 45–50 days for completion; 100 units of ecdysone, given to a 4th instar intermoult nymph, will bring all cycles to completion in seven days.

In intermoult nymphs and adults, injection of ecdysone produces sexuality in parasites without moulting of hosts.

Dr. J. D. Fulton (National Institute for Medical Research, London) spoke on some aspects of research on trypanosomes. The relationships of the three African trypanosomes, *T. brucei*, *T. gambiense* and *T. rhodesiense*, was first discussed. They cannot be distinguished morphologically and have sometimes been regarded not as separate species but as three biological races of a single species, *T. brucei*. Their distinguishing characters were dealt with in detail. The Tinde experiment started by Corson in 1934 had thrown considerable light on the affinities of these three parasites, on their physiological characters as well as on host–parasite relationships. The significance of polymorphism in trypanosomes and the presence of cytoplasmic inclusions, each character a facet of the host–parasite relationship, were discussed. The evidence suggested that sexual processes had not been demonstrated in these parasites. Dr. Fulton also described experiments on transformation in trypanosomes by means of deoxyribonucleic acid using drug resistance as a marker. The results obtained were negative or equivocal.

Dr. R. E. Hungate (University of California, Davis) described the factors influencing rumen protozoa. He showed how the ruminant provides to its symbiotic microbiota relatively constant temperature, moisture, osmotic pressure, *p*H, anaerobiosis, and food. The effect of variations in these factors on the protozoa was discussed, and the ability of the latter to withstand the normal variations in these factors was emphasized. In particular, the stress at the time of transfaunation was considered, including the devices for maintaining the necessary environment. The chief factor causing variation in the rumen microfauna is presumed to be differences in food. The effects of food may not be direct but mediated through bacteria which act upon it before they are consumed by the protozoa. The utilization of cellulose and the rapid ingestion of starch were stressed as characteristic of certain protozoa. The possible importance of protozoa during adaptation from hay to a high grain ration was presented.

Dr. A. R. Timms (Louisiana State University School of Medicine) dealt with the work of that School on schistosome enzymes. He explained how *Schistosoma mansoni* converts glucose quantitatively to lactic acid by the Embden–Meyerhof scheme of phosphorylating glycolysis which is also a major pathway for glucose utilization in mammalian tissues. However, enzymes from the parasite and the host, although catalysing the same biochemical transformations, are immunologically different.

Antimonials were shown by Bueding *et al.* to produce their antischistosomal activity, at least in part, by specific inhibition of phosphofructokinase activity of *S. mansoni*, leaving the host's phosphofructokinase largely uninhibited.

A protease was described which was thought to be in the gut of schistosomes, and which showed a marked specificity for hæmoglobin and globin when compared with other blood proteins. The possibility was discussed that this enzyme might provide an essential source of amino-acids for the parasite by degrading the host's hæmoglobin.

The paper by Dr. D. Fairbairn (McGill University, Canada) dealt with the physiology of hatching and larval exsheathment in nematodes. A result of investigations conducted in Canada and Australia has been that hatching and exsheathing of infective ascarid eggs and trichostrongyle larvæ can now be induced *in vitro* under conditions which closely resemble those in the host's intestinal tract. Under controlled conditions of *p*H, oxidation-reduction potential, temperature and concentration of free carbon dioxide, these processes occur at a rate comparable to that observed *in vivo*, and with identical morphological changes. Quantitative differences in the requirement of individual species for the components of this complex stimulus have been observed and positively correlated with conditions in the host. Exsheathment of *Haemonchus contortus*, for example, occurs only at high concentrations of free carbon dioxide such as are present in the sheep rumen, while a condition for optimal hatching of *Ascaris lumbricoides* eggs is that the carbon dioxide concentration be much lower, approximating that found in the small intestine of feeding mammals. The free-living infective eggs and larvæ cannot continue their development in the absence of the foregoing stimulus, which is in general peculiar to the host's intestinal tract, and thus ensures the transition to a parasitic existence. The processes of hatching and exsheathment constitute an internal response to stimulation, which is enzymic and results in digestion of the egg-shell and sheath.

The final paper, by Dr. P. P. Weinstein (Bethesda), was concerned with excretory mechanisms and excretory products of nematodes. The mechanism by which excretory products are released is poorly understood. Passage via cuticle, elimination by gut and so-called 'excretory system' may occur alone or in combination. This latter system was named primarily on teleological grounds, and little evidence for excretory function is available. Such a 'system' has been implicated in osmoregulatory activity and in moulting. Possible mechanisms for discharge of fluid such as secretion accompanied by preferential reabsorption were considered. The gut may play an important part in excretion of waste and the role of the cuticle and other structures was evaluated. The identification of the chemical nature of excretions and secretions was of possible importance regarding sensitization, development of functional immunity and pathological effects in the host. Products from axenically cultured parasitic nematodes are the only ones available for analyses. Much waste is apparently liberated as amino-acids and peptides or as organic acids, especially C_5 types. *In vitro* culture methods in defined media are urgently required for these studies.

A summary of the conference was given by Dr. Ernest Bueding (Louisiana State University) as follows. Since the occurrence of many biochemical reactions has been demonstrated in a large number of animal species of unicellular organisms and of plants, there has been a tendency to over-emphasize similarities and to overlook differences among various forms of life. Such biochemical differences may concern metabolic pathways and reactions (for example, fermentation products). In addition, it has been demonstrated that enzymes catalysing the same reactions in different species may not be identical with each other. Considerable biochemical differences have been uncovered not only between parasites and their hosts, but also among various parasitic species, even though they may be related to each other morphologically and taxonomically. Therefore, in biochemical studies of parasites, similarities and differences must receive equal attention and any one-sided view will result in a distorted picture. It is suggested that comparative biochemistry should be concerned with the nature of biochemical variability from patterns common to many forms of life; this, in turn, should contribute to a better understanding of biochemical evolution to a parasitic form of life.

J. D. FULTON

VIBRATIONS: THEIR EFFECTS AND ANALYSIS

IN this technological age, in which larger and larger amounts of power are being harnessed to aid mankind, it is not surprising that the unwanted adjunct of power, vibration, is becoming of great importance. Thus, for example, it is not only the public itself which is annoyed and fatigued by the noise of jet aircraft, but also the fabric of aeroplanes is now tending to show signs of fatigue and to crack. Again, in the field of supersonic transport, the motion of the aircraft can be of a frequency (around 5 c./s.) at which the body is least attuned to absorb the vibrational energy imposed upon it.

These topics, together with the more industrial problems of machinery vibration and occupational diseases arising from excessive vibration of drills, etc., were the subjects discussed at the recent meeting of the Acoustics Group of the Physical Society, held on January 20, at the Imperial College of Science and Technology, London.

Dealing first of all with problems of the vibration isolation of machinery, Mr. P. H. Allaway (Absorbit, Ltd.), in a review paper, gave an excellent appraisal of the many types of isolating materials and systems now available. The effect of the rigidity of the ground or floor structure was discussed, together with the effect of damping in shock vibration isolation. He emphasized the need for choosing the right type of installation for any type of application, and showed in the ensuing discussion a wealth of valuable experience and 'know-how'.

Dr. John Agate (Ipswich and East Suffolk Hospital) presented a somewhat frightening picture of the influence of vibrations in industry on the hands of operating personnel. Four diseases were mentioned in all: cysts of carpal bones, osteo-arthritis, soft-tissue injuries and a circulatory disturbance known as Raynaud's phenomenon. The small cysts can only be seen on X-ray examination and are not of any significance. Osteo-arthritis of the elbows is, of course, not confined to people working with vibrating machinery, though there is ample evidence of this being a contributory cause. Raynaud's phenomenon, which Dr. Agate dealt with extensively, is a circulatory disorder of the blood stream in the hands, and it arises from their operating in an environment of heavy vibration. In such cases, there is a lessening of the blood stream in the small arteries of the hands, and it is typified by the fingers and even the whole hand becoming white or blue. It is difficult to schedule the disease as a disability, since most fingers show these symptoms in the cold; further, many workers using vibrational types of machinery do not suffer with this loss of circulation in the fingers in the warmth of their factories, but only show the symptoms later in colder conditions, and then about six to eighteen months after first exposure.

The prevention of this disease is not easy, since any frequency less than 600 c./s. causes the damage to the arteries, the range of 40–125 c./s. nevertheless being the most serious. The lesson to be learnt is, in fact, the need for automation for any processes of this kind. Since this can only be introduced in very special instances, the solution is still unavailable and needs further scientific study.

In view of the recent interest in supersonic transport aircraft, Flight Lieut. Guignard's description of the work of the R.A.F. Institute of Aviation Medicine on physiological effects of low-frequency vibration was both interesting and significant from the point of view of design. The jet liners of the present have a natural frequency of oscillation of the fuselage structure somewhere in the region of 4–6 c./s., and pilots placed in the cockpits of these aircraft have been known to suffer from the up-and-down movements of that part of the long fuselage. The experiments described illustrate the reasons for this, and emphasize the need for designing away from such frequencies. It is found (Fig. 1) that if a male person, in a relaxed sitting posture, is vibrated vertically through the seat, a resonance occurs at some 5 c./s., the amplification of the head and shoulders being as much as three times that of the seat movement. Above this resonance frequency, the damping in the body eliminates harmonics of higher frequency. The effect of tensing the body is favourable, increasing the resonant frequency to 6·3 c./s. and also increasing the damping, thus reducing the amplitude of head movement by a small though significant amount. At these frequencies around 5 c./s., tests in the United States indicate a serious reduction in performance with poor eye-correlation, fatigue and pains in the chest.

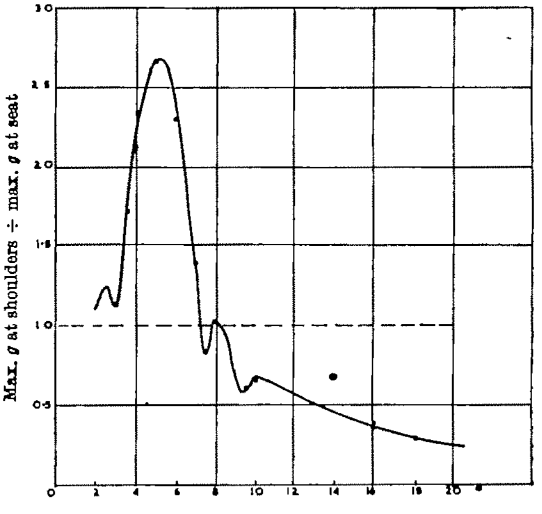

Fig. 1. Ratio of shoulder to seat acceleration plotted against frequency. Note the sharp resonance of the body at 5 c./s.

It is clear that this is a phenomenon of vital significance in the design of aircraft. The problem is not confined to aircraft, however. Ships cannot in any way claim freedom from vibrations of this frequency, while even trains, 'juddering' to a standstill in railway stations, set up exactly this type of disturbance.

Two complementary papers concerning the fatigue of aircraft structures due to vibrations set up by jet noise were presented respectively by Prof. E. J. Richards and Dr. B. L. Clarkson, of the Department of Aeronautics, University of Southampton. Jet noise arises from the turbulent motion of the jet gas as it mixes with the surrounding air. The total radiated energy is only a very small fraction of the energy of the jet, however (say, a hundredth of 1 per cent), and elaborate methods of experimentation have to be devised to measure the turbulence functions which are directly related to the radiated noise. In his paper, Prof. Richards described the space-time correlator and other apparatus used to obtain the spectrum of turbulence as seen by an observer moving with the jet stream. The relevant speeds of convection were discussed and a first attempt made to predict the radiated sound from the spectra of turbulence measured in this way.

There is, in general, no one discrete frequency of sound emitted from a jet. Consequently, the adjoining structure is vibrated randomly by the noise field and can in theory oscillate in an infinity of modes of oscillation. If a large number of modes do occur in practice, it is clear that the theoretical approach to prediction must be different from that adopted if the vibration is of a relatively simple kind. Dr. Clarkson's paper described experiments carried out on the vibrations of the rear part of the *Caravelle* airliner due to jet efflux, a programme carried out jointly by the firm, Sud-Aviation, and the University of Southampton. The analysis was concentrated on the strains in the centre of four panels of the fuselage skin aft of the engine nozzle; the first three being in line between two circumferential frames and the fourth being adjacent to the centre gauge of the first group but separated by a frame. Correlation measurements indicated that the lower frequencies (up to 500 c./s.) were associated with essentially overall vibration modes and have low strain amplitude. At the higher frequencies, having the larger strains, the frames tended to act as boundaries and the mode of vibration was confined to the stringers and panels between any two adjacent frames. In these measurements on this particular aircraft, the main resonance peak in each panel occurs at about 600–700 c./s. and has been identified with the fundamental stringer twisting mode (that is, adjacent panels are 180° out of phase). Strain response in the higher frequency range of 800–1,000 c./s. appears to be associated with a considerable number of closely spaced resonant frequencies.

This method of analysis using correlation techniques is a considerable step forward in the study of random vibrations of aircraft, ships and submarines, and the success outlined in the paper suggests that greater use should be made of this method of vibration analysis.

E. J. RICHARDS

A CONVECTIVE-TURBULENCE THEORY OF THUNDERSTORMS

By DR. N. RAMALINGAM

Director, Regional Meteorological Centre, New Delhi

IT is well known among meteorologists that in practical forecasting of thunderstorms the methods in current usage, such as the parcel methods, etc., of analysis of the dry-bulb and wet-bulb soundings of the atmosphere plotted on $T - \varphi$ grams or other thermodynamic diagrams, are often unreliable.

The initiation of thunderstorms, at least in such cases that occur in a calm atmosphere over land on hot afternoons, as experienced over India in the hot pre-monsoon months, has been investigated from the point of view of modern knowledge about turbulence. In doing that, however, the limiting condition:

$$\frac{\rho_1 - \rho_0}{\rho_0} > \frac{27\pi^4 k\nu}{4gh^3} \qquad (1)$$

given by Lord Rayleigh[1] from his mathematical investigation of the motion in the Bénard cells formed, when a fluid of thickness h in equilibrium with its density ρ_1 at the top being greater than its density ρ_0 at the bottom breaks down into convection, is taken as the main physical basis. In the above expression ν is the kinematic coefficient of viscosity, and k is the coefficient of conduction of heat of the fluid.

Indeed, even so far back as 1925, Brunt[2] made it very clear that some of the phenomena associated with thunderstorms can be explained in the same way, and that the violence of thunderstorms would appear to indicate that a high degree of instability is built up before the breakdown occurs. This suggestion, however, does not appear to have been pursued quantitatively.

In his original paper, Rayleigh gave the limiting condition as:

$$\beta' r > \frac{27\pi^4 k\nu}{4h^4} \qquad (2)$$

where $\beta'(= -\beta)$ is the lapse-rate; and $r = g\alpha$, α is the coefficient of expansion of the fluid, and g is the acceleration due to gravity.

Since he was considering a fluid of small thickness h, he took:

$$\beta' = -\beta = \frac{\theta_1 - \theta_0}{h}$$

θ being the departure from the equilibrium temperature, and:

$$r = g\alpha = g(\rho_1 - \rho_0)/\rho_0(\theta_1 - \theta_0)$$

hence, (2) reduces to (1).

If, however, we take a layer of air of thickness z, then we may take $\beta' = \dfrac{d\theta}{dz}$; and from the relation $\rho_1 = \rho(1 + \alpha d\theta)$ and taking $\rho_1 - \rho = d\rho$, we may write : $r = g\alpha = \frac{g}{\rho}\frac{d\rho}{d\theta}$, so that (2) reduces to :

$$\frac{d\rho}{\rho} > \frac{27\,\pi^4 k\nu}{4\,g\,z^4}\,dz \qquad (3)$$

Since we are dealing with atmospheric air where the heat is gained only at the bottom near the ground, the rest of the motion being adiabatic, the last condition becomes :

$$\frac{dP}{P} > \frac{27\,\pi^4\gamma k\nu}{4\,g\,z^4}\,dz \qquad (4)$$

where P is the atmospheric pressure, and γ is the well-known adiabatic coefficient for air (= 1·4). Since in the atmosphere, except very close to the ground, transmission of momentum and heat is brought about mainly by the turbulent eddies, the above limiting condition may be written as :

$$\frac{dP}{P} > \frac{27\,\pi^4\gamma K_M K_H}{4\,g\,z^4}\,.\,dz \qquad (5)$$

where K_M is the eddy viscosity and K_H is the eddy conductivity.

Since we are dealing with a large-scale phenomenon, such as the thunderstorm, much error may not arise, if, for simplicity, K_M is assumed to be nearly equal to K_H. Then from the expression for K_H quoted by Sutton[3], we may write :

$$K_H = l^2_H \sqrt{\left(-\frac{g}{\theta}\frac{d\theta}{dz}\right)}$$

where l_H is the mixing length and θ is the potential temperature. Further we take, with Prandtl, $l_H = \varkappa z$, where $\varkappa$ is the well-known von Kármán's constant (= 0·38). Then the limiting condition (5) reduces to :

$$d \log P > \frac{27\,\pi^4\gamma\varkappa^4}{4}\,(-\,d \log \theta) \qquad (6)$$

Summing up for all possible eddies, Σ of left-hand side must exceed Σ of the right-hand side. In other words, integrating from some level, l, to the ground-level, 0, we get the critical condition for the convective turbulent breakdown in the atmosphere as :

$$\frac{\log \dfrac{P_1}{P_0}}{\log \dfrac{\theta_0}{\theta_1}} > \frac{27}{4}\,\pi^4\gamma\varkappa^4 \qquad (7)$$

(taking $\varkappa = 0·38$, the right-hand side = 19·2 which is rounded off as 19. If $\varkappa$ is taken as = 0·37, the right-hand side could be taken as 17).

We therefore get the critical condition $\log \frac{P_1}{P_0} \Big/ \log \frac{\theta_0}{\theta_1}$ should exceed 19 (taking $\varkappa = 0·38$) for the breakdown in the equilibrium of the air to occur.

Since the left-hand side occurs as a ratio the logarithms may as well be taken to the base 10. Of course, to be more precise, one can take the potential temperatures corresponding to the two virtual temperatures. But this will not be of much significance. (Conversely, from a calculation of the left-hand side from the atmospheric sounding obtained before the occurrence of the thunderstorm, one can derive the value of von Kármán's constant by this independent method.)

For purposes of practical forecasting of thunderstorms while P_0 (about 1,000 millibars) refers to the ground-level, it will be sufficient if P_1 is taken as 500 or 600 millibars, since the lowest layer of 15,000 ft or so only will be of importance ; θ_0 and θ_1 are the potential temperatures corresponding to the dry-bulb temperatures at those levels.

Examination of a few random cases of the actual soundings of the atmosphere taken before thunderstorms seem to confirm the validity of the above critical condition (7). The same critical condition also appears to be applicable to other thunderstorms other than of the simple type assumed.

If the early morning sounding shows the ratio to just fall short of 19, one may be able to forecast whether a thunderstorm is possible later in the day by merely predicting whether insolation will be able to raise θ_0, so that the ratio exceeds 19, as the only other variable θ_1(P_1 and P_0 already having been chosen by us) is likely to remain practically the same, unless there is reason for believing that the air mass would have altered much in the few hours.

Of course, for a correct application of the critical condition (7), the sounding must strictly be obtained from a direct vertical ascent, as the soundings normally obtained by balloons are really 'spread over' observations.

In passing, it may be mentioned that while in the parcel method, etc., the $T - \varphi$ gram is used as an energy diagram, in this case the $T - \varphi$ gram serves little purpose except perhaps as a nomogram to read off the potential temperatures, and to judge the moisture content.

It follows, incidentally, from the above investigation that, surprisingly, the moisture in the air apparently seems to play a minor, or subsidiary, part so far as the initiation of the thunderstorm is concerned. Examination of the $T - \varphi$ grams referred to above also seem to confirm this view. This, perhaps, seems to be the reason why in the parcel method, thunderstorms are found to occur even in cases when the latent instability, as shown by the positive area, is little or nil ; and vice versa. Lest it should be misunderstood, it is clarified further. Water vapour being a constituent of the air, it also partakes fully in the convective processes of the air as outlined above ; and once the breakdown occurs in the equilibrium of the air, the water vapour will also undergo convection with its attendant condensation and release of latent energy, which all go to aggravate further and accelerate the vertical motions. If the moisture content of the air particularly at the lower levels is large, as shown by the wet-bulb temperatures being closer to the dry-bulb temperatures in the soundings, then when the breakdown occurs, there will be greater condensation and greater release of energy resulting in violent vertical motions that result in the formations of great vertical columns of cumulo-nimbus clouds, showers and all other attendant phenomena normally associated with thunderstorms. If the moisture content is less, and still the critical number is exceeded, and the breakdown occurs, there will probably be only development of a few cumulus clouds ; while if the air is practically dry, then something like what is known among aviators as 'clear air turbulence' will presumably result.

More details of this investigation will be published elsewhere.

VARIATION OF ELECTRON DENSITY IN THE IONOSPHERE WITH MAGNETIC DIP

By SHEILA CROOM, AUDREY ROBBINS and J. O. THOMAS

Cavendish Laboratory, Cambridge

THIS communication describes how the average ionospheric electron density (N_h) measured at local noon on quiet days in December 1957, at a series of fixed heights (h) in the F region, varies with the magnetic dip (I). The electron density profiles were deduced from observed $h'(f)$ curves by a method already described[1,2], the calculations having been carried out on the electronic digital computer, *Edsac II*, in the Mathematical Laboratory in the University of Cambridge.

It has been previously reported[3] that in September 1957 N_h varied with magnetic dip in an interesting and somewhat unexpected manner, and that the variation differed from that of the peak electron density N_mF2, particularly in the lower parts of the $F2$ layer. It was shown that, in these parts, the N_h (I) curve had maxima in N_h, where the dip was about 60° and there was evidence that the maxima occurred nearer the magnetic equator as greater heights were investigated.

Our previous investigations have now been extended to include the northern winter solstice, particularly in order to investigate whether N_h is abnormally large, corresponding to the well-known enhancement of N_mF2 described below.

When values of N_mF2 observed at different places are studied, two anomalies can be found: one, called the winter or seasonal anomaly, in which the values of N_mF2 are greater than expected on a simple theory in the winter hemisphere at medium and high latitudes, and the other, called the December or non-seasonal anomaly, in which, all over the Earth, the values measured in December are greater than expected. These variations have recently been studied in detail by Yonezawa[4]. At places in medium and high latitudes in the northern hemisphere, the two anomalies are in the same sense, so that the recorded values of N_mF2 are greater in December and January than at any other time of year.

Fig. 1 shows N_h at noon at a series of different heights plotted against magnetic dip for the month of December 1957, and may be compared with Fig. 1 in our previous communication[3], which was plotted for September 1957. The values plotted for N_h are the averages for all the good records for the ten International Quiet Days. The average values of N_h are estimated to be correct to within 5 per cent for stations in the northern hemisphere. The results for the southern hemisphere stations are probably somewhat less accurate. The observatories for which the points are plotted are listed in order of magnetic dip in Table 1.

The main features of the curves shown in Fig. 1 are the striking maxima in N_h, which occur at the larger values of h, in the form of a narrow peak centred on a dip of 70° (N.) and extending 10° on either side. The values of N_h at the 70° peak are probably exceptionally large as a result of the abnormally high sunspot number for this month ($\bar{R} = 239$).

Once it is realized that the winter anomaly in N_h may be restricted to a comparatively narrow

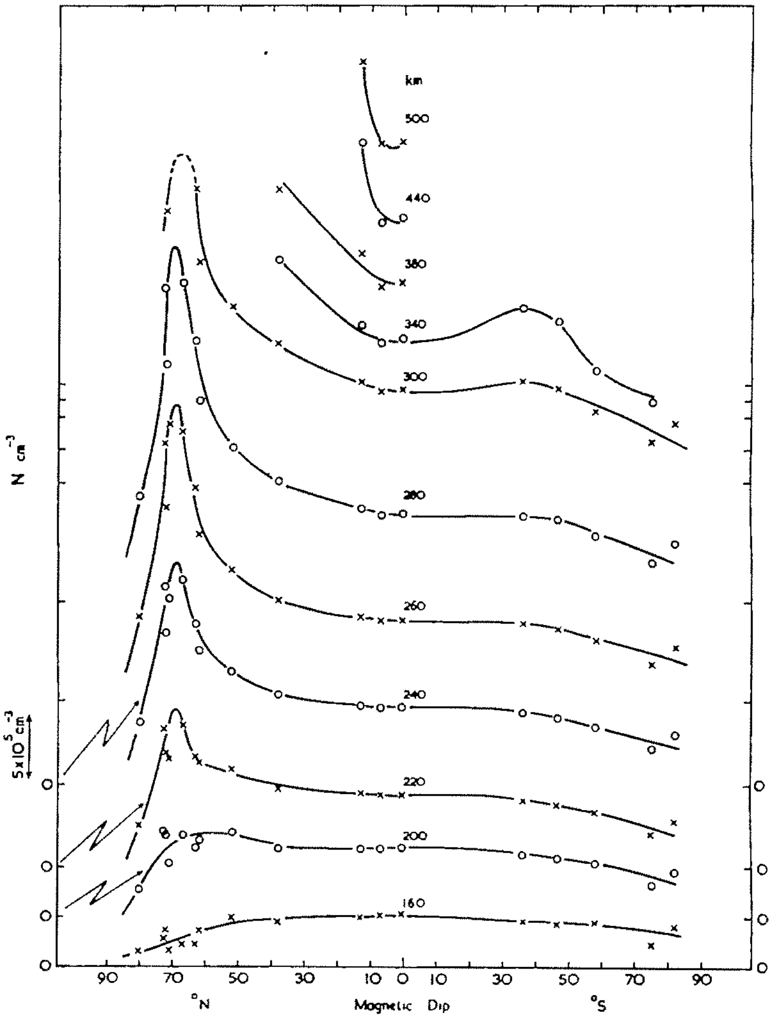

Fig. 1 Variation with magnetic dip of the mean quiet electron density N at a series of fixed heights in the F region at local noon in December 1957. The zero of the scale for the electron density at each height is marked. The stations used are listed in order of decreasing magnetic dip in Table 1

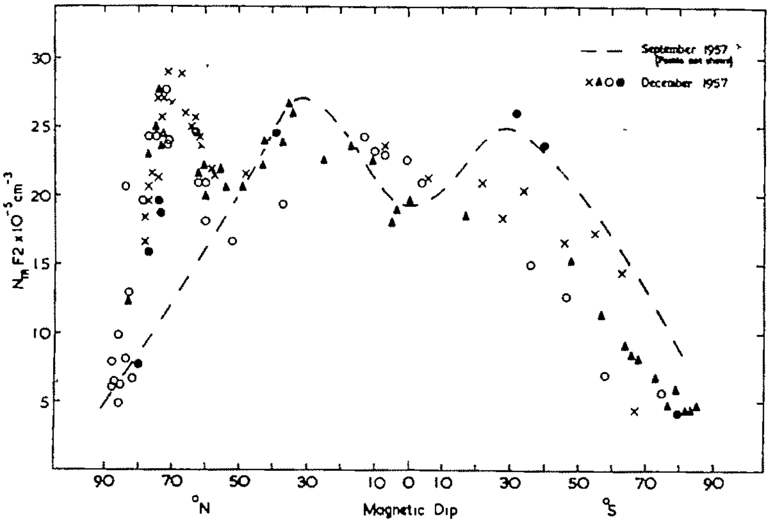

Fig. 2. Variation with magnetic dip of the monthly median noon values of N_mF2 in December 1957 for four geographical longitude zones. ×, 30° W.–50° E.; ▲, 50° E.–180° E.; ●, 180° W.–130° W.; ○, 130° W.–30° W. The broken line shows for comparison the variation of the monthly median N_mF2 for September 1957 (individual values are not shown)

range of dip angles, it is of interest to investigate how N_mF2, at the peak of the layer, depends on the dip in the same month. In Fig. 2 the monthly median values of N_mF2 for 12.00 L.M.T. are plotted against I, and it is at once evident that this quantity, also, exhibits the same comparatively narrow peak of increased ionization.

The monthly median values of N_mF2 have been separated in Fig. 2 into four main zones of geographical longitude. It is clear that the 70° peak in N_mF2 is independent of longitude. The broken line in Fig. 2 shows, for comparison, a smoothed curve of the variation of N_mF2 against dip in September 1957. This curve shows no indication of a peak near $I = 70°$ (N.). Results similar to those for December 1957 were obtained for the months of October and November 1957 and January 1958.

When values of N_mF2 are plotted against dip for other hours of the day and night, it is found that a similar maximum occurs near $I = 70°$ (N.) throughout the daylight hours. It appears at sunrise, is most prominent near noon and then decreases until at midnight it has disappeared.

Similar analyses carried out on observations for years with smaller sunspot numbers indicate that the size of the peak decreases with decreasing sunspot number.

A similar peak in N_mF2 occurs in the southern hemisphere in winter when the sunspot number is high. This is illustrated in Fig. 3, where a smooth curve has been drawn through the monthly median values of N_mF2 for July, September and December 1957.

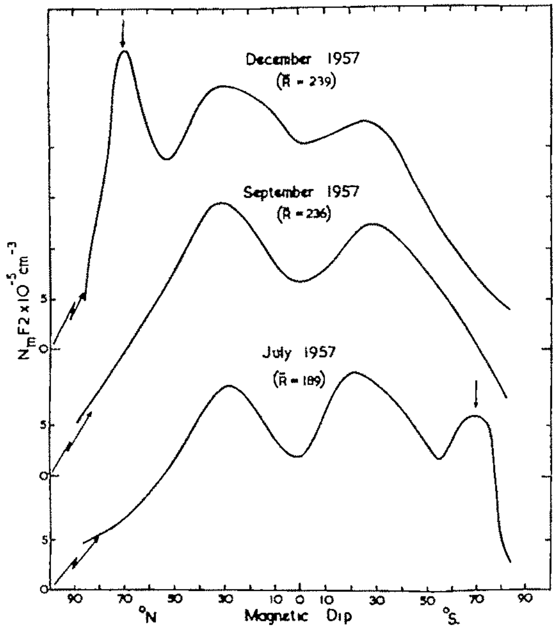

Fig. 3. Variation with magnetic dip of monthly median N_mF2 at local noon in July, September and December 1957. $\bar{R}$ is the monthly average relative Zurich sunspot number

A comparison of the variation of N_h with dip in December 1957 (Fig. 1) with the variation of N_mF2 for the same month (Fig. 2) indicates that, below about 300 km., there is no evidence in N_h of the minimum which occurs at 50° (N.) in N_mF2, and that N_h in this month decreases uniformly towards the magnetic equator from a dip of 60° (N.), as it did in September 1957 (Fig. 1 of ref. 3).

SIGNIFICANCE OF RIBONUCLEIC ACID IN THE MECHANISM OF FORMALDEHYDE-INDUCED MUTAGENESIS

By DR. THOMAS ALDERSON

Institute of Animal Genetics, University of Edinburgh

THE present article reports the significant occurrence that formaldehyde exhibits no mutagenic activity towards *Drosophila melanogaster*, by the larval feeding method, unless ribonucleic acid is present in the treatment medium.

In a study of the mode of action of chemical mutagens, the use of a chemically defined and axenic treatment medium is clearly essential for the precise definition and discrimination of both qualitative and quantitative effects. Such a medium has now been developed for *Drosophila melanogaster* by Sang[1], in which the dose-response for the main dietary constituents on the duration of larval life has been determined. On the basis of these findings, he has formulated an optimal medium (Table 1), which allows larval development to be completed in approximately 4·4 days ; this compares with 4·1 days when the same strain is allowed to develop on an optimal supply of killed yeast. The omission of ribonucleic acid from the synthetic medium prolongs the period of larval development to about seven days[1]. Thus, although *Drosophila* larvæ can normally develop without an exogenous supply of ribonucleic acid, its addition accelerates development, indicating that preformed purines (or their nucleosides or nucleotides) are assimilated, to supplement or replace the natural synthetic process.

Table 1. COMPOSITION OF STANDARD CULTURE MEDIUM

	(gm.)		(gm.)
Yeast ribonucleic acid	0·4	Na$_2$HPO$_4$	0·189
Casein ('Genatosan-low vitamin')	5·00	Aneurin	0·0002
		Riboflavine	0·0010
Fructose	0·75	Nicotinic acid	0·0012
Cholesterol	0·03	Calcium pantothenate	0·0016
Lecithin	0·40	Pyridoxine	0·00025
Agar ('Oxoid-Kobe No. 1')	3·00	Biotin	0·000016
NaHCO$_3$	0·14	Folic acid	0·0010
KH$_2$PO$_4$	0·183	Water to 100 ml.	

The folic acid content of this medium is about ten times the minimum required in a medium containing ribonucleic acid, since it is known that the folic acid requirement is increased when ribonucleic acid is omitted from the diet. This excess does not interfere with development when optimal ribonucleic acid is supplied in the food.

The *Drosophila* stock used in the present study, and in previous experiments[3,4], the Oregon-*K* strain, does, however, require a dietary supply of cytidine for normal growth and development[2] ; this was supplied as cytidylate (0·025 per cent). Since ribonucleic acid contains cytidylate, this was not added when ribonucleic acid was present. The medium will be referred to as the synthetic medium (*sm*) when ribonucleic acid is omitted, and as *sm* + ribonucleic acid when the acid is present. Ordinary medium is the yeast–maize meal–treacle medium normally used for culturing *Drosophila* in this laboratory. It was decided to omit the egg sterilization procedure and autoclaving of the medium normally essential with this technique, since formaldehyde itself effectively suppresses microbial growth, and propionic acid is used as a fungicidal agent, as in previous experiments. The procedure for treatment of larvæ and brood pattern determinations for sex-linked lethal mutation rates is as previously described[3]. The age of larvæ is counted from the time of hatching from the egg. The larval developmental time for treated larvæ was counted from emergence from the egg to puparium formation. In most experiments the larval developmental time is compounded of pre-treatment, treatment and post-treatment times.

It was decided to test the mutagenic activity of formaldehyde in the presence and in the absence of ribonucleic acid, now made possible by Sang's refined culturing technique.

Experiments were carried out at a constant concentration of formaldehyde ($2 \cdot 0 \times 10^{-2}$ *M*) with different levels of ribonucleic acid in the treatment medium. The optimal concentration of the acid in the synthetic medium has been shown by Sang to lie between 0·4 and 0·7 per cent[1]. Table 2 shows the results obtained over the concentration range 0·2–0·6 per cent ribonucleic acid, where larvæ were kept on the treatment medium for the whole of larval life. The mutagenic activity of formaldehyde in the first brood is seen to be significantly lower at the lowest concentration of ribonucleic acid tested (0·2 per cent) than at the 0·3 per cent ribonucleic acid level ($\chi^2 = 15 \cdot 36$ with one degree of freedom). The mutation frequencies of the first broods over the range 0·3–0·6 per cent ribonucleic acid are not significantly different from one another (heterogeneity $\chi^2 = 0 \cdot 18$ with three degrees of freedom). Second broods are sampled as a check against possible changes in brood patterns by influences on the speed of germ-cell development ; these are seen to be not significantly different from one another over the ribonucleic acid concentration range tested (heterogeneity $\chi^2 = 1 \cdot 98$ with four degrees of freedom). It should be noted that in the formaldehyde-containing synthetic medium (at least, at the concentration used here), the larvæ do not

Table 2. EFFECT OF THE CONCENTRATION OF RIBONUCLEIC ACID ON THE MUTAGENIC ACTIVITY OF FORMALDEHYDE, WHEN TREATMENT IS FOR THE ENTIRE LARVAL LIFE

survive if the ribonucleic acid concentration is less than 0·2 per cent or greater than 0·7 per cent.

While it was not possible to test the mutagenic activity of formaldehyde in the absence of ribonucleic acid, by treating larvæ throughout larval life, this difficulty was overcome after consideration of the following observations.

In a study of the response of *Drosophila* larval germ cells to the mutagenic activity of orally administered formaldehyde, Auerbach[5] has determined the patterns of sensitivity for each of the four days of larval life. In her initial experiments, larvæ were put on the formaldehyde food at the beginning of the stage to be treated, and transferred to ordinary food after 24 hr. It was afterwards discovered that, as formaldehyde food on which the larvæ are feeding loses its mutagenic activity within 24–48 hr.[5], transfer to ordinary food is not necessary; this means that approximately the same sensitivity pattern is obtained if the larvæ are allowed to complete development on the formaldehyde food as the ones transferred after only 24 hr. of treatment[5]. The ineffectiveness of formaldehyde food after 24–48 hr. does not appear to be due completely to loss of mutagenic activity of the medium[6], but rather to the development of a tolerance in treated larvæ which makes them incapable of responding to even a slightly deteriorated formaldehyde medium. However, if the larvæ which have spent some time on treated food are transferred to freshly treated food, formaldehyde can produce mutations in cells which would have failed to mutate with continued exposure to the old medium[7]. Observations on the sensitivity pattern of response of larval germ cells suggest the coincidence of the sensitive period with the auxocyte stage in primary spermatocyte development[6], that is, the protracted growth stage which precedes meiosis in the larval testis. Auxocytes are found to make their first appearance about the twelfth hour of the first day of larval life, which coincides with the beginning of sensitivity to formaldehyde food. Consequently, treatment of larvæ during the first day of larval life, whether the larvæ are allowed to complete development on the treatment medium, or are transferred to ordinary food after 24 hr., involves approximately the same effective treatment. In view of this latter consideration, it may be reasoned that the experiments quoted in Table 2 simply mean that, at the lowest concentration of ribonucleic acid (0·2 per cent), the appearance of the sensitive stage is delayed until the formaldehyde food has almost lost its effectiveness. This argument is unlikely, however, as the developmental time at 0·2 per cent ribonucleic acid is about the same as, and in one case (0·6 per cent) less than, for acid concentrations giving maximum mutagenic effect. Moreover, differences in speed of larval development do not necessarily result in altered mutational response to formaldehyde[7], although decreases in the mutagenic activity of formaldehyde have been reported after pronounced increases in the duration of larval life[7]. Nevertheless, it was decided to attempt to slow down development slightly on the synthetic treatment medium containing ribonucleic acid to obtain a comparable developmental time with the treatment medium where ribonucleic acid is omitted. This was achieved by halving the cholesterol concentration and substituting 0·004 per cent choline for the lecithin; these constituents were chosen as they have no known connexion with nucleic acid metabolism. Such a medium will be referred to as '*sm* + ribonucleic acid delayed'.

In consequence of the preceding observations, it was decided to pre-feed larvæ on *sm* + ribonucleic acid (0·4 per cent) medium for some time before transfer to the treatment medium, thus assuring that sensitive cells are present at the time of treatment. This procedure, however, has the disadvantage that a proportion of sensitive cells normally affected in the first brood will have passed the sensitive stage at the time of treatment; consequently, lower mutation rates occur.

Table 3 summarizes the results obtained when 18-hr. larvæ are treated for 24 hr., after which they are allowed to complete development on ordinary medium. In the absence of ribonucleic acid, no formaldehyde-induced mutagenic activity is detected; the spontaneous mutation-rate of the Oregon-*K* strain

Larval developmental time (days)	6·5	5·5	6·5
Per cent survivors	> 70	> 70	> 70
	First broods		
No. chromosomes examined	608	501	557
No. lethals	0	28	21
Per cent sex-linked recessive lethal mutations	0 0	5·6	3·8
	Second broods		
No. chromosomes examined	352	367	354
No. lethals	0	5	3
Per cent sex-linked recessive lethal mutations	0·0	1·36	0·85

varies normally from 0·1 to 0·3 per cent recessive sex-linked lethal mutations. In both acid series there is significant mutagenic activity, and although '*sm* + ribonucleic acid delayed' has the same developmental time as '*sm*', it shows no significantly different mutagenic response from '*sm* + ribonucleic acid' in either the first or second brood (χ^2 = 2·5 and 2·14, with one degree of freedom, respectively).

A comparable experiment where 24-hr. larvæ were treated by the same procedure is shown in Table 4. Again, no induced mutations are detected in the absence of ribonucleic acid, whereas activity is significant in both the '*sm* + ribonucleic acid' and '*sm* + ribonucleic acid delayed'; the mutational response of the latter two treatments do not differ significantly from one another in either the first or second brood (χ^2 = 2·57 and 0·52 with one degree of freedom, respectively). In this series, treatments were also carried out where the concentration of ribonucleic acid was reduced to 0·1 per cent (*sm* + ribonucleic acid (0·1 per cent)), and one where 0·4 per cent thymus gland deoxyribose nucleic acid replaces ribonucleic acid (*sm* + deoxyribonucleic acid (0·4 per cent)): no significant activity was detected after either treatment. Deoxyribonucleic acid was used here as it is known not to be utilized by *Drosophila* larvæ, and is even toxic to them[8]; at the concentration used here, however, the toxic effect is negligible.

Table 6. EFFECT OF RIBONUCLEIC ACID ON THE MUTAGENIC ACTIVITY OF FORMALDEHYDE, WHEN 15-HR. LARVÆ ARE TREATED FOR 2 DAYS, AND RE-TREATED ON FRESH FORMALDEHYDE FOOD FOR A FURTHER 2 DAYS

Treatment medium	*sm*	*sm* + RNA (0 4 per cent)	*sm* + RNA (0·4 per cent) delayed
Formaldehyde concentration		2 × 10^{-2} *M*	
Larval developmental time (days)	7 0	6 0	6 8
Per cent survivors	70·8	45·4	55 0
	First broods

No. lethals	2	16	22
Per cent lethals	0·27	2·5	3 3
	Second broods		
No. chromosomes examined	355	362	337
No. lethals	1	7	6
Per cent sex-linked recessive lethal mutations	0 28	1·93	1·78

A further series (Table 5) is summarized, where 15-hr. larvæ were left on the treatment medium for three days, after which they were allowed to complete development on ordinary food. Once more, no induced mutations are detectable in the absence of ribonucleic acid, whereas '*sm* + ribonucleic acid' and '*sm* + ribonucleic acid delayed' both show high mutation-rates which are not significantly different from one another in either the first or second brood (χ^2 = 1·98 and 0·43 with one degree of freedom, respectively). The developmental times of '*sm*' and '*sm* + ribonucleic acid delayed' were almost identical, despite the increased duration of the treatment.

A final series was carried out, where advantage was taken of the fact that if larvæ, which have spent some time on formaldehyde-treated food, are transferred to freshly treated food, formaldehyde can produce mutations in cells which would have failed to mutate with continued exposure to the old medium[7]. Daily transfers to fresh formaldehyde food were carried out, but the effect on the development was found to be too pronounced except at low (0·5 × 10^{-2} *M*) formaldehyde concentrations. However, less frequent transfers proved successful. Table 6 shows the results obtained when 15-hr. larvæ were left on formaldehyde food for two days, followed by transfer to fresh formaldehyde food for a further two days, after which they were allowed to complete development on ordinary food. No induced mutagenic activity was detectable in the absence of the acid, whereas both ribonucleic acid treatments showed mutagenic activity. The two acid treatments are not significantly different from one another in either the first or second brood (χ^2 = 0·73 and 0·02, with one degree of freedom, respectively); the developmental times of '*sm*' and '*sm* + ribonucleic acid delayed' were approximately the same.

Table 7. EFFECT OF RIBONUCLEIC ACID ON THE MUTAGENIC ACTIVITY OF URETHANE, WHEN TREATMENT IS FOR THE ENTIRE LARVAL LIFE

Treatment medium	*sm*	*sm* + RNA (0·4 per cent)
Urethane concentration	0·1 per cent	
Total developmental time	16–19 days	10–14 days
Per cent survivors	49	67·5
	First broods	
No. chromosomes examined	964	648
No. lethals	14	10
Per cent sex-linked recessive lethal mutations	1·45	1 54
	Second broods	
No. chromosomes examined	892	1,087
No. lethals	12	9
Per cent sex-linked recessive lethal mutations	1·34	0 83

That this phenomenon is not a general one for chemical mutagens is seen from Table 7, where I tested the mutagenic activity of urethane by the larval feeding method. Newly hatched larvæ were allowed to develop throughout larval life on the synthetic treatment medium under axenic conditions, and the mutagenic activity of urethane was tested in the presence and absence of ribonucleic acid; for both treatments urethane was autoclaved in the medium. Since urethane prolongs the pupal period, and adult emergence time is scattered over several days, developmental times are given from hatching from the egg to peak adult emergence. No difference was observed between the mutational response of the two series (first and second brood χ^2 = 0·275 and 1·25, respectively).

An analysis of the mechanism by which ribonucleic acid mediates the mutagenic activity of formaldehyde is now in preparation for publication.

I wish to make my acknowledgments to the Medical Research Council for financial support, and Prof. C. H. Waddington for supplying laboratory facilities.

EFFECTS OF STARVATION ON THE ABILITY OF ISOLATED RAT DIAPHRAGM TO INCORPORATE LABELLED AMINO-ACIDS INTO ITS PROTEIN AND TO RESPOND TO THE INFLUENCE OF INSULIN ON THIS PROCESS

By Dr. K. L. MANCHESTER*
Department of Biochemistry, University of Cambridge

IT is now well established that insulin *in vitro* stimulates the incorporation of labelled amino-acids into the protein of isolated rat diaphragm[1-4], although the mechanism by which this action is brought about remains unknown. The earlier experiments of Krahl[2] seemed to suggest that insulin enhanced incorporation of amino-acid into protein by favouring carbohydrate utilization, a process which would make available more energy and possibly more pentose for the synthesis of ribonucleic acid and protein. Addition of glucose to the medium, in place of insulin, could also simulate incorporation. More recently, both Manchester and Young[3] and Wool and Krahl[4] have described conditions under which addition of glucose has no observable effect on incorporation and yet where addition of insulin produces a very marked and consistent stimulation. However, Wool and Krahl[4] also find that a stimulating effect of glucose on incorporation of amino-acid can be observed with diaphragm from rats which have starved for 48 hr., the rate of incorporation in the absence of glucose being markedly depressed by comparison with diaphragm from the non-fasting animal. Under these conditions the effect of insulin on incorporation is very severely reduced. Similar results have not been obtained in this laboratory, and in the present communication evidence is presented to the effect that the nutritional status of the diaphragm donor (that is, the length of time, up to 48 hr., that the animal has starved before removal of the diaphragm) does not seriously modify the effect of insulin on incorporation, nor can the action of insulin on amino-acid incorporation be simulated in any way by glucose.

Diaphragm was obtained from female rats of either the albino Wistar or the black-and-white hooded strain, weighing about 120 gm. and fed a stock laboratory diet[6]. Diabetic animals had been rendered diabetic by subcutaneous injection of alloxan (200 mgm./kgm.) at least two weeks before removal of the diaphragm. Such animals had non-fasting blood sugar-levels above 500 mgm. per cent, but after the withdrawal of food for 24 hr. the blood sugar-level dropped to an average of about 215 mgm. per cent. Hemidiaphragms were incubated for 2 hr. at 37° C. in a bicarbonate buffer[7] *p*H 7·4, gassed with oxygen plus carbon dioxide (95 : 5) in the presence of 1–^{14}C–glycine (1 μmole/ml.), with or without addition of glucose (2·5 mgm./ml.) and/or insulin (Boots crystalline insulin – 22 units/mgm., 0·1 unit/ml.). The procedure for the removal and incubation of the diaphragm and for the preparation of protein samples has been previously described[5]. In the experiments with diaphragm from Wistar rats the glycine added to the medium had a specific activity of about 400 μc./m.mole; the protein prepared from diaphragms was collected on 1-cm.^{2} plastic disks as infinitely thick samples[8]. In the experiments with diaphragm from the hooded rats the glycine added to the medium had a specific activity of about 80 μc./m.mole; the diaphragm protein was collected as a thin film on 7·5 cm.^{2} aluminium disks, and its content of radioactivity assessed in counting equipment with an efficiency for carbon-14 of about three times that of the equipment used for counting the infinitely thick protein samples. The figures shown for incorporation of radioactivity into protein of diaphragm from the two strains of rat are therefore not comparable. Other experiments in which the rate of incorporation by diaphragm of the two strains has been compared suggest that the respective rates are fairly similar.

In the absence of insulin, incorporation of ^{14}C-glycine into the protein of diaphragm from Wistar and hooded rats starved 24 hr. was slightly (13 and 12 per cent) reduced by comparison with diaphragm from non-fasting animals (Table 1). A further 24 hr. of starvation did not appreciably reduce incorporation in either strain. In the presence of insulin, incorporation into protein of diaphragm from Wistar rats starved for 24 hr. had declined 10 per cent by comparison with diaphragm from non-fasting animals, but incorporation did not decline further when the diaphragm donors starved for 48 hr. (Table 1). Starving hooded animals for 24 hr. did not depress the rate of incorporation of glycine by the isolated diaphragm in the presence of insulin, though with diaphragm from rats starved for 48 hr., incorporation was appreciably (21 per cent) lower (Table 1). With diaphragm from the Wistar rats the magnitude of the effect of insulin on incorporation of ^{14}C-glycine was unchanged by the nutritional pre-treatment of the diaphragm donor, and was about four times the size of the change induced by starvation (Table 1). With

Table 1. EFFECT OF FASTING ON THE INCORPORATION OF ^{14}C-GLYCINE INTO THE PROTEIN OF ISOLATED RAT DIAPHRAGM AND THE STIMULATION BY INSULIN OF THIS PROCESS

Strain of rat from which diaphragm taken	Food withheld (hr.)	Radioactivity in diaphragm protein		
		No insulin added	Insulin added (0·1 unit/ml.)	Difference
		(counts/min./disk)		
Wistar	0	281 ± 16 } $P < 0·1$	442 ± 19	161
	24	242 ± 14 }	406 ± 17	164
	48	250 ± 9	401 ± 16	151
		(counts/min./mgm.)		
Hooded	0	11·9 ± 0·94 }	18·0 ± 1·22 } $P < 0·05$	6·1
	24	10·4 ± 0·88 } $P < 0·1$	17·6 ± 1·56 } $P < 0·1$	7·2
	48	9·8 ± 0·62 }	14·2 ± 0·85 }	4·4

Each figure is the mean ± S.E. of the mean of six observations. The value of P for a difference which is significant is indicated. The effect of insulin is significant in each instance ($P < 0·01$). No glucose was added to the medium.

diaphragm from the hooded strain the size of the insulin effect was somewhat reduced when the donor had starved for 48 hr., though this diminution was not apparent with diaphragm from rats starved for 24 hr. (Table 1). The magnitude of the insulin effect, however, was still twice the diminution in incorporation produced by starvation.

Addition of glucose or pyruvate to the medium in either the presence or absence of insulin has previously been shown to have no observable effect on the incorporation of a large number of different ^{14}C-labelled amino-acids into the protein of diaphragm from Wistar rats starved for 20–24 hr.[3]. Addition of glucose to the incubation medium, again in the presence or absence of insulin, has now been found to have no appreciable or significant effect on the incorporation of ^{14}C-glycine into the protein of diaphragm from rats of either strain starved for 48 hr. or from alloxan-diabetic Wistar rats starved for 24 hr. (Table 2). The magnitude of the insulin effect is also unchanged by the addition of glucose, and is many times larger than any effect of glucose.

Since Wool and Krahl[4] were using rats of the Sprague-Dawley strain, the results presented here may indicate that there are quite large quantitative differences in the response of different strains to the effects of starvation, glucose and insulin on amino-acid incorporation. In particular, rats of the Sprague-Dawley strain, as judged by the ability of the isolated diaphragm to incorporate labelled amino-acids into protein, appear to be incapacitated to a greater extent by starvation than are those of the Wistar and hooded strains. In other words, availability of the energy required for protein synthesis becomes a rate-limiting factor at an earlier stage during starvation in the Sprague-Dawley rat. Perhaps because of this an enhancement of the rate of amino-acid incorporation by addition of glucose is more readily observed with the isolated diaphragm of this strain[5]. On the other hand, slight variations in the conditions under which the animals are reared and kept may lead to quite large differences in the response of diaphragm to the conditions investigated.

The results presented here, taken in conjunction with earlier papers from this laboratory[3,9], do indicate, perhaps more clearly than hitherto, that insulin *in vitro* invariably stimulates incorporation of labelled amino-acids into the protein of isolated diaphragm from rats in varied nutritional states, and that this effect of insulin is not dependent upon an effect of insulin on glucose uptake, neither can it be simulated by glucose alone, nor is it observably modified by the simultaneous presence of glucose. The availability of material acting as a source of energy for protein synthesis, even for the alloxan-diabetic animal, is not therefore the rate-limiting step in amino-acid incorporation in diaphragm, and the action of insulin on this process does not appear to be brought about by its action on carbohydrate metabolism. The slightly reduced basal incorporation observed here which results from starvation for 24 or 48 hr. may be a consequence of a reduced rate of secretion and lower circulating level of insulin than is the case in the non-fasting animal.

Although insulin enhances the rate of accumulation of a non-utilizable amino-acid, α-amino isobutyric acid, by diaphragm[10], it has not so far proved possible to show an effect of insulin on the accumulation of naturally occurring amino-acids in the same way[11]. The bulk of the evidence at the present time[11-13] is against the view that insulin enhances amino-acid incorporation into muscle protein by affecting the transfer of amino-acids into the cell, but the details of the mechanism by which insulin regulates amino-

Table 2. EFFECT OF THE ADDITION OF GLUCOSE TO THE MEDIUM ON THE INCORPORATION OF ^{14}C-GLYCINE INTO THE PROTEIN OF DIAPHRAGM FROM FASTING RATS AND THE STIMULATION BY INSULIN OF THIS PROCESS

Food withheld (hr.)	Strain of rat from which diaphragm taken	Addition to the medium	Radioactivity in diaphragm protein		
			No insulin added	Insulin added (0·1 unit/ml.)	Difference
				(counts/min./disk)	
48	Wistar	No addition	187 ± 8*	317 ± 11	130
		Glucose (2·5 mgm./ml.)	208 ± 9	312 ± 14	104
				(counts/min./mgm.)	
48	Hooded	No addition	10·7 ± 0·68	16·7 ± 1·29	6·0
		Glucose (2·5 mgm./ml.)	11·7 ± 0·81	17·5 ± 0·82	5·8
				(counts/min./disk)	
24	Alloxan-diabetic Wistar	No addition	200 ± 14*	337 ± 23	137
		Glucose (2·5 mgm./ml.)	203 ± 11	338 ± 21	135

Each figure is the mean ± S.E. of the mean of six observations. The effect of the addition of glucose is in no case significant. The effect of insulin is significant in each instance ($P < 0·01$).

* These figures cannot be compared, as the experiments were performed at different times with different batches of ^{14}C-glycine in which the content of radioactivity had not been rigidly standardized.

acid incorporation and protein synthesis remain obscure.

I am grateful to Prof. F. G. Young for much help and encouragement during the performance of this work.

A HEPATOTOXIN CAUSING LIVER DAMAGE IN FACIAL ECZEMA OF SHEEP

By Dr. N. A. WORKER

Ruakura Animal Research Station, Department of Agriculture, Hamilton, New Zealand

FACIAL eczema is a serious disease affecting sheep and cattle in many areas in New Zealand. The disease is essentially an acute cholangitis which, in more severe cases, is accompanied by obliteration of medium-size bile ducts, with bile ductule proliferation, and a gradual replacement of liver parenchyma in the portal areas with fibrous tissue as the lesions become more extensive[1]. It has recently been shown that this condition is due to a toxic principle present in the fungus *Sporidesmium bakeri*, Syd., a saprophytic organism growing in association with pasture[2]. Rabbits and guinea pigs are also known to be susceptible to the disease, liver lesions of a generally similar nature having been demonstrated in these species after feeding toxic grass and pure fungal culture[3,4], and ether extracts of these[4], and also after the injection of extracts into the vena porta[5].

Little is known of the behaviour of the toxin in the animal body. It has been generally assumed that the toxin is transported via the portal circulation to the liver and excreted into the biliary system, where it sets up an inflammatory reaction which in turn produces lesions characteristic of the disease[6]. There is, however, no experimental evidence to substantiate that the portal circulation is the main route by which the toxin enters the liver, nor is there any direct proof of the presence of the toxin or of a possible metabolite in the bile. These problems have recently been studied in some detail at this Station.

Transport of Toxin to the Liver

In an attempt to confirm the portal route of entry into the liver, and in order to obtain information on the rate of uptake of the toxin from the circulation, a comparison of the effectiveness of fungal extracts administered by the portal vein and by the jugular vein was made. A range of doses was tested on New Zealand white rabbits of mixed sex weighing 1,000–1,200 gm. Twelve animals were allotted to each group at random. All animals were slaughtered eight days after treatment. Morbid anatomy and histological examinations of specimens taken *post mortem* were carried out by D. C. Dodd, veterinary diagnostic officer, of this Station.

It has been found that over wide levels of dosage (ranging from the equivalent of 300 ml. to 1,000 ml. of fungal culture), macroscopic lesions of varying severity, consistent with facial eczema liver damage, were produced after intraportal injection of toxic extracts (Figs. 1, 2). The extent and severity of these

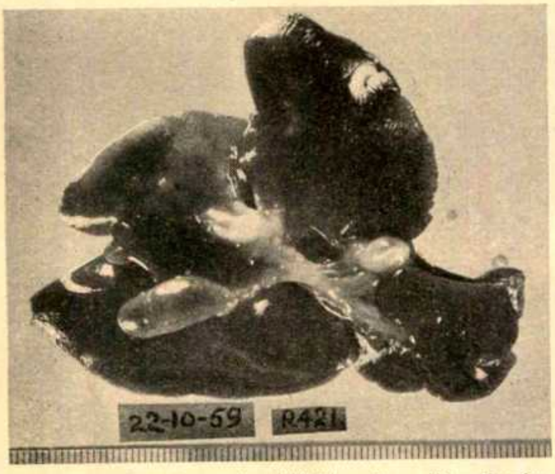

Fig. 1. Severe liver damage in rabbit fed a culture of *Sporidesmium bakeri*, Syd. for 14 days. Note extreme œdema of hepatic ducts, common bile duct and cystic duct, and marked fibrosis of left central lobe. Scale in millimetres

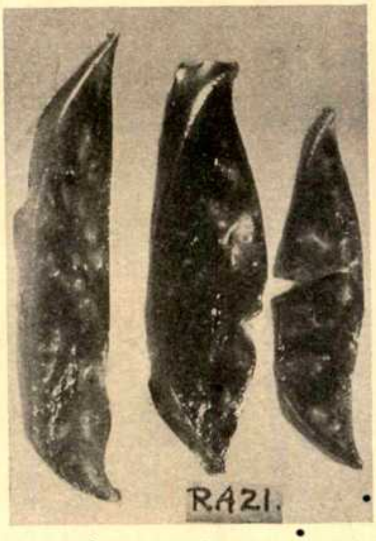

Fig. 2. Transverse sections of liver from same rabbit illustrating generalized damage to duct system

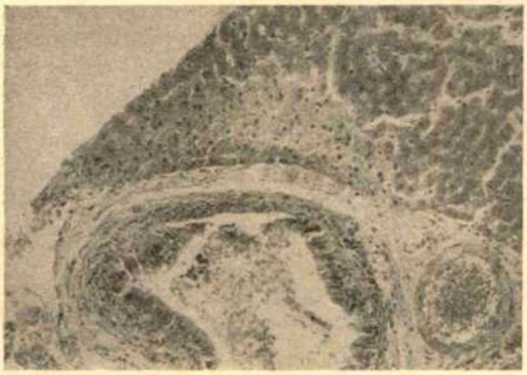

Fig. 3. Photomicrograph of local necrosis and desquamation of biliary epithelium of large bile duct with moderate periductal œdema and fibrosis. Hæmatoxylin and eosin. (×70)

lesions were confirmed histologically (Figs. 3, 4). After injection of comparable amounts of toxic material into the jugular vein, on the other hand, no evidence of any gross liver damage was found, and all livers, with the exception of two, were histologically normal. The two positive livers were graded as 'mild' on histological examination.

These observations provide support for the hypothesis that the portal circulation is the main route by which toxin enters the liver following absorption from the intestinal tract. The evidence also indicates that the toxin is relatively unstable in the systemic circulation and, on the basis of these findings, it would appear that uptake of toxin via the lymphatic system is of little or no importance in so far as the development of liver lesions is concerned. The fact that the toxin appears to be inactivated on entering the general circulation would suggest also that the uptake of toxin by the liver cells is instantaneous and that the lesions produced must, therefore, be due to that fraction of the toxin removed from the portal blood the first time it passes through the liver sinusoids.

Appearance of Toxin in the Bile

Prior to the work reported here, it had already been shown, in independent studies, that the first bile duct lesions begin to appear approximately three to six hours after intraportal injection of toxic extract[5], which strongly suggested that if toxin is excreted into the bile it must reach relatively high concentrations there very shortly after injection. It was decided, therefore, to collect bile from animals for varying intervals following injection of toxic extract and to test this bile directly for toxicity. Rabbits, of mixed sex, weighing 600–1,000 gm. were used. 'Donor' animals were fitted with a cannula into the common bile duct and injected intraportally with toxic extract equivalent to 5 litres of fungal culture. Toxicity was assessed by dripping the bile from the donor into the top of the duodenum of successive 'recipient' animals, up to six recipient animals being used in each experiment. This technique was decided upon after it had been shown independently that toxic extracts dispersed in fresh hepatic bile and administered in this way were effective in producing typical lesions of severe facial eczema liver. The technique offered the further advantage of minimizing the time for which any toxin present would be in contact with bile and also avoided the necessity for any form of chemical or physical treatment of the bile, which would have been necessary in order to reduce its bulk were it to be administered by any other route.

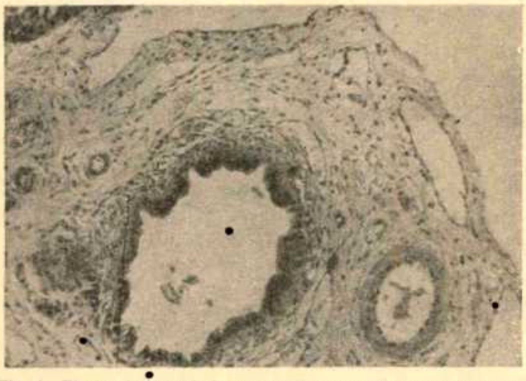

Fig. 4. Photomicrograph demonstrating typical severe periductal œdema and fibrosis, and cellular infiltration of periductal tissue. Hæmatoxylin and eosin. (×70)

Fourteen such experiments have been carried out to date. The technique employed in each has been essentially the same, with the exception that the intervals over which individual recipient animals received bile from the donor animal were varied in the different experiments from half an hour up to one and a half hours, although within each experiment the intervals were kept constant. In eleven of the fourteen experiments the presence of toxic material in the bile of the donor animal has been unequivocally demonstrated by the development of typical liver lesions of facial eczema in the recipient animals. The negative results obtained in three experiments were believed to be due to loss of toxicity of fungal extract prior to injection into the donor. In view of the wide individual variation in the degree of liver damage between animals which was observed in each experiment, it is difficult to assess with any degree of accuracy the rate of excretion of toxin from the liver. The evidence obtained so far does clearly indicate, however, that appreciable amounts of toxic material are present in the bile in as little as half an hour after injection of extract, and that maximal output appears to occur within two hours of injection. Whether the observed toxicity of bile was due to the presence of the toxin *per se* or to physiologically active degradation products of the toxin is not known. Attempts to settle this important issue must await elucidation of the chemical structure of the toxin.

The fact that toxicity has been detected in bile, using the technique outlined, is of considerable interest for our understanding of the pathogenesis of this disease, since it quite clearly provides strong evidence for supposing that in the intact animal an enterohepatic circulation of toxic material may occur. This might assist in explaining, at least in part, the 'progressive' nature of the disease[1], and the fact that such seemingly minute traces of toxin are capable of producing, in many cases, lesions of the most severe form (White, E. P., unpublished work).

LETTERS TO THE EDITORS

PHYSICS

Copper-Cellulose Complexes

THE criticism recently levelled by Bayley and Rose[1] at our findings concerning a copper–cellulose complex in wood implies that they have neither appreciated the weight of our evidence nor have they realized the complexity of the problems involved. We recommend that they should see all our papers on this matter[2-6]. We are answering these criticisms on behalf of the authors involved in our papers as we were responsible for the physical evidence presented.

When copper is taken up by wood and complexes in such a way as to be detectable by our methods, the question is whether the particular complex concerned is associated with the cellulose on one hand (as we believe we have proved), or with the encrusting substances (as Bayley and Rose would have us believe) on the other. This latter possibility must be rejected on several clear grounds. (*a*) The complex gives identically the same electron diffraction patterns whether whole wood or wood α-cellulose is used and, moreover, these are invariable for a wide range of α-celluloses and a wide range of metals. (*b*) The complex is oriented with respect to the cellulose microfibrils. This is demonstrated both by the electron diffraction diagram and by the dichroic properties resulting when wood or α-cellulose is treated with a copper salt and stained with dithioxamide. There is no evidence that the encrusting substances have the requisite properties. (*c*) The uptake/concentration curves demand that the copper shall be adsorbed on a surface, and the electron diffraction diagrams prove that the copper ions then form a regular two-dimensional array. The microfibrils provide such a regular surface, but there is no evidence that the encrusting substances fulfil this requirement.

We have emphasized in our papers that copper, in particular, occurs in more than one form in wood impregnated with copper salts and of course it may form a complex with some of the encrusting materials. We have been careful not to exclude this possibility though we have at present no evidence for it; our evidence refers exclusively to a copper–microfibril complex. It is not quite certain that the complex involves any part of the glucose residue in cellulose, and non-glucose sugars that are known[7] to be an integral part of the cellulose microfibril may be involved. The facts, however, that the same electron diffraction diagram is obtained for celluloses varying widely in xylose content, and that if non-glucose sugars are involved they would need to be closely and regularly distributed over the surface of microfibrils, argue strongly in favour of glucose. For the same reasons we are of the opinion that the hydroxyl groups of glucose are involved rather than occasional carboxyl substituents.

It is perhaps at first sight peculiar that microfibrils embedded in lignin and hemicelluloses possess the necessary free surfaces, and it is presumably this that formed the starting point of Bayley and Rose's[1] comments. It must be remembered, however, that by no means all of the microfibrils either in wood or in wood α-cellulose become complexed. The evidence so far is that less than about a quarter of the total microfibrillar surface is apparently capable of adsorbing metals in the manner under consideration. The evidence shows that this much of the surface is available in wood, and unless our evidence can be shown to be at fault this must be accepted.

We would suggest that, until firm evidence to the contrary has been presented, our hypothesis is the only reasonable interpretation of the facts.

Sorption of Activated Gases by Titanium Films

GALE[1] has shown that the rate of gas sorption of an evaporated titanium film is enhanced by a Penning gauge connected to the getter vessel, and experiments are in progress in my laboratory to determine the nature of the sorption process when the gas is activated in this manner. In a recent communication it has been shown that the rate of gas sorption of titanium films for air, nitrogen, oxygen and hydrogen are a function of the current flowing in the Penning head[2], even when the metal film is at a positive potential and therefore repels positive ions. The increase in the rate of sorption of active gases greatly exceeds that due to the pumping action of the Penning head, but inert gas atoms are only sorbed by the Penning head and are probably embedded in metal sputtered from the cold cathodes.

I have proposed[3] that the enhanced rate of sorption of an active gas arises primarily from the Penning discharge atomizing the gas, so that it diffuses more readily between the grain boundaries of the metal deposit. Possibly the active states of the gas particles also increase their rate of chemical reaction at the nascent metal surface; but this can scarcely explain an enhanced rate of sorption if one considers that sorption proceeds through a superficial layer of reaction products. Titanium films evaporated at low pressure (< 0·1μ mercury) have almost bulk density, because when oxidized by heat the resulting layer of titanium oxide has a refractive index near that of solid rutile in the polycrystalline state. Evaporated titanium films grow from a large number of nuclei, and the condensate must be composed of tightly packed micro-crystallites possessing a large interior area for adsorption and reaction with residual gases. However, the rate of sorption of a fresh film would rapidly decline, because the gas molecules are unable to reach the interior surface. Dependence of the rate of diffusion of the sorbed gas on the structural form of the deposit may account for the conflicting reports of the effects of ionization (or atomization) of gases on the rate of sorption of barium (see, for example, refs. 3 and 4), because with this metal the grain size and distribution can vary considerably with the evaporation conditions.

The investigations of the gettering properties of titanium have recently been refined and show more clearly the dependence of the rate of sorption on the ionization (atomization) of the residual gas. The Penning ion-source was mounted in a 3-in. diameter tube with titanium cathodes of 3 in. diameter and in a magnetic field-strength of 400 gauss. When operated at applied voltages between 3 and 5 kV., the ion-source had a pumping speed of about 1–5 litre/sec. The sorption vessel consisted of a stainless steel chamber 6 in. in diameter and 6 in. high (1,400 cm.^{2} area) with the Penning head mounted on top. The positive terminal of the high-tension supply was grounded, so that the evaporated getter repelled gas ions. The vacuum seals were made with metal gaskets and the pressure measured with an Alpert type ion-gauge. The titanium was evaporated from tungsten filaments after baking the system and isolating the chamber from the oil diffusion pump at a pressure of 10^{-7} mm. mercury. The gas to be sorbed was admitted to the getter chamber from a reservoir through a calibrated leak. Rates of sorption were measured in the pressure interval 10^{-7} to 10^{-5} mm. mercury.

In the earlier work[1], a thick titanium film was used for a series of sorption measurements over a range of pressures. In this investigation a fresh film (≃ 100 Å. thick) was used for each sorption measurement, and a period of 1 min. was allowed after each evaporation for the system to gain equilibrium before the instantaneous rate of sorption was measured. At the pressures used, the outer surface of the getter film was rapidly covered by adsorbed gas, and this was shown by the fact that the rate of sorption fell to a negligible amount ($< 0{\cdot}002$ litre μ/sec.) after a few minutes if the Penning head was not on. In Fig. 1 are shown the mass sorption-rates of titanium films for oxygen when measured at different pressures and under the foregoing conditions. The Penning head was operated at constant voltages of 3 and 5 kV., and the current flowing in the head has been plotted in Fig. 1 as a function of pressure. When the two sets of curves are compared, it can be seen that the rate of sorption is practically a linear function of the Penning discharge current, which itself is not exactly proportional to pressure. At high values of ionization current the rate of sorption tends to increase less rapidly, presumably because the getter film is more quickly saturated by the gas.

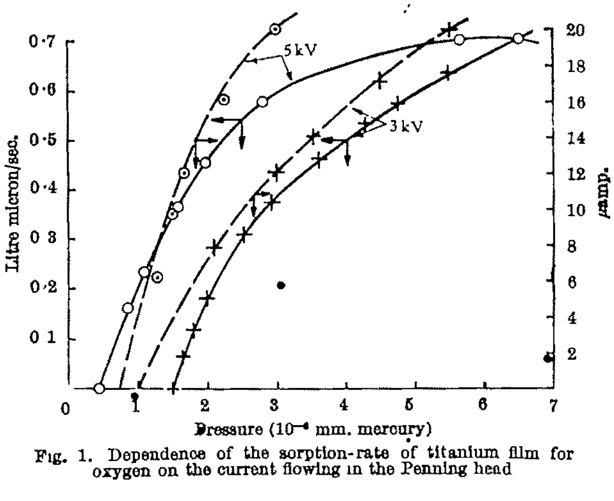

Fig. 1. Dependence of the sorption-rate of titanium film for oxygen on the current flowing in the Penning head

In a recent communication in *Nature*, Stow[5] reported that titanium films deposited on the negative ion collector of a hot-cathode ion-pump gave the same rate of sorption whether the ion-pump was in operation or not. From this he concluded that ionization did not play an essential part in the sorption process. However, his pressure measurements were made with a Penning gauge and if, as suggested here, such a discharge supplies atomized neutral particles to the film, then operation of the gauge would have enhanced the rate of sorption in both cases. The ionization (and related dissociation) efficiency of a Penning system is known to be superior to that of a triode type ion-source. These criticisms do not in any way detract from his substantiation of the value of titanium as a getter. Stow's subsequent experiments comparing barium and titanium getters were based on measurements made with Alpert ion-gauges, and molecular dissociation could have still been effective.

The theory advanced in this communication to explain the enhanced rate of sorption of a deposit also accounts for the enhanced rate of oxidation of thin metal films in glow discharges. There is no evidence that oxide films on metals grow faster in the presence of active oxygen, but penetration of a metal film by gas atoms so that the crystallites are oxidized on many sides would explain this phenomenon.

Acknowledgments are made to Mr. W. Sheraton, who made the sorption measurements described here, and to the Directors of Edwards High Vacuum, Ltd., for permission to publish this communication.

Sedimentation and Effective Viscosity

I WISH to comment on the communication by Prof. G. J. Kynch on this subject[1]. With the author's reservations (see following letter), the derivation of equation (8) seems satisfactory, though it is difficult to see the need for the constant added in equation (6). The final equation may be written in the form :

$$V_r = \frac{u}{V} = \frac{(1 - c)}{\mu_{re}} \tag{1}$$

where V_r is relative settling velocity of particles; u is actual settling velocity of particles; V is settling velocity of a single typical particle at infinite dilution;

c is volume concentration of solids; μ_{re} is effective relative viscosity of suspension of similar particles having the same density as the fluid and a volume concentration of c. This equation makes interesting comparison with equations due to Gurel[2],

$$V_r = \frac{(1-c)^2}{\mu_r} \qquad (2)$$

where μ_r is the measured relative viscosity of the suspension, and Hawksley[3],

$$V_r = (1-c)^2 \exp - \frac{2\cdot5c}{1-0\cdot609c} \qquad (3)$$

and Steinour[4],

$$V_r = (1-c)^2\, 10^{-1\cdot82c} \qquad (4)$$

All four equations contain a term which represents the reciprocal of the effective relative viscosity of the suspension; this is multiplied by $(1-c)^2$ in equations (2), (3) and (4), and by $(1-c)$ in equation (1). The latter term is due to the familiar 'return flow' effect, also considered by the other workers; the additional factor $(1-c)$ in equations (2), (3) and (4) appears because a typical particle is considered as settling in a fluid of density equal to that of the suspension as a whole rather than one of density equal to that of the dispersing liquid. Kynch, however, considers a typical particle differing from its fellows only in that its density is equal to that of the dispersing liquid. The time-average velocity of this particle is stated to equal the mean fluid velocity "modified by the pressure gradient in the fluid due to the [other] falling particles". Following the application of an equation in which the density of the particle reverts to its original value, a value of the settling velocity is obtained by neglecting the above pressure gradient. Equation (1) is therefore advanced only as an 'approximate' relationship for the settling velocity.

It is then stated that the equation "seems to agree with experimental results up to concentrations of about 20 per cent", ref. 5 being quoted. This agreement is actually rather poor, for the curve referred to shows that the product $\mu_r V_r$ is proportional to $(1-c)^2$ rather than $(1-c)$; thus distinct non-linearity is present at concentrations of less than 20 per cent when the data are plotted on the basis of $\mu_r V_r$ against $(1-c)$. Moreover, in the derivation of equation (1), it was stated that the viscosity was that of an otherwise similar suspension in which the particles had the same density as the fluid, that is, a stable suspension. Accordingly, a graph has been drawn in which the relative viscosities used are for stable suspensions of spherical particles[6] and the settling velocities for otherwise similar slightly unstable suspensions having particle size ratios of 1·40 : 1 (ref. 7) and 1·03 : 1 (ref. 2), respectively (Fig. 1). In neither case does equation (1) apply satisfactorily, although for the suspensions having particles of wider size-range the gradient of the line near the origin is not greatly different from that predicted by the theory. The suspensions of closely sized particles represent an important limiting case on which few data are available; the unique settling behaviour of these suspensions merits further attention.

It should be added in fairness that equation (2) also requires modification before agreement with experimental results is obtained[8]. Fair agreement with the present data has, however, been given by equation (3), linear plots being obtainable for concentrations up to more than 30 per cent with gradients of 1·26 (size ratio 1·03 : 1) and 0·88 (size ratio 1·40 : 1), compared with a theoretical value of 1·09. These figures illustrate the importance of reducing the size-range of particles used in sedimentation tests if the results are to be compared with elementary theory.

[7] Oliver, D. R., Ph.D. thesis (Birmingham, 1954); see Table L, Class 2, Col. 2).

Before I comment on Dr. Oliver's communication, I feel that an apology is due to readers for a number of errors in my communication in *Nature* of October 24. They made a simple derivation of equation (8) appear complicated though not, I hope, unintelligible.

Dr. Oliver's comments are valuable, as he is familiar with the difficulties of this subject, and I am glad that he considers that the derivation of my equation seems satisfactory and produces no theoretical reasons for disagreeing with it. Incidentally, the other equations which he mentions are referred to and commented upon by Ward in the reference given in my letter.

At present the experimental results on suspensions seem complicated and often have surprising features. Objections can be raised to all theoretical formulæ or semi-empirical formulæ yet suggested, and the reasons for the complications are not fully understood. In these circumstances, as in many others, the most useful theory is simple, generally acceptable, containing well-defined approximations with some physical meaning. It may then be possible to suggest reasons for discrepancies between the approximate theory and accurate experiment which will lead to an improved formula. I hope that the derivation in my letter might help in this way and suggest further experiments.

Dr. Oliver clearly does not accept my statement that my equation "seems to agree with experimental results up to concentrations of 20 per cent", although he admits that the other equations are not good either. He mentions my reference to the article by Ward, where there is certainly a curve intended to show that $\mu_r V_r$ is proportional to $(1 - c)^2$ rather than $(1 - c)$. I was not entirely satisfied with this conclusion and I looked at the data used in the article, which were obtained by Oliver[2]. In fact, his results for 'Kallodoc' spheres in water and in an alcohol–water mixture and for glass spheres in glycerol–water agree quite well with my formula, as I stated, and at least as well as with the formula with the factor $(1 - c)^2$. Only for 'Kallodoc' spheres in lead-nitrate solution was there serious error and for suspensions with nearly equi-sized particles. Dr. Oliver plots two curves using viscosity data for stable suspensions, one giving fair agreement and the other, for nearly equi-sized particles, giving bad agreement.

From my equations (1)–(4), which I reproduce in order:

$$v = v_f + v_p : \quad U = v' - v : \quad U\mu = V\mu_0 : \quad v' = u$$

together with the assumption $v_f = -cu/(1 - c)$, I deduce that:

$$\mu u = (1 - c)(\mu_0 V + \mu v_p)$$

The discrepancies in my simple formula can be attributed to its assumption that $v_p = 0$, or to the other assumption that μ is the effective viscosity μ_{re}.

Whatever the cause, the discrepancy for equi-sized spheres is puzzling and requires more consideration.

METALLURGY

Influence of Guinier–Preston Zones on the Electrical Resistivity of Age-hardening Alloys

Federighi and Passari[1] have recently directed attention to the increase in electrical resistivity associated with the early stages of ageing in binary aluminium alloys in which age-hardening involves pre-precipitation effects such as the formation of Guinier–Preston zones. Recent work in this Establishment has shown that this effect occurs in more complex ternary and quaternary aluminium alloys and is particularly marked in the Al–Zn–Mg–Cu system.

The effect is shown in Fig. 1, which compares present observations on an Al–Zn–Mg alloy with earlier work by Durer and Köster[2]. Ageing at 20° C. yields a significant increase in resistivity whereas at high temperatures the normal fall in resistivity associated with precipitation is observed. Very similar results have now been obtained on commercial Al–Mg–Si alloys (Fig. 2) and the effect appears to be typical of a number of binary and ternary aluminium alloys, including duralumin type alloys[3], all of which are known to develop Guinier–Preston zones in the initial stages of hardening and particularly during low-temperature ageing. The lack of coincidence between the resistivity and hardness increases has been ascribed to the dependence of the resistivity on electron scattering by aggregates of criticial dimensions and on the effect of coherency strains in the matrix[4,5]. In the Al–Zn–Mg system it is known that low-temperature ageing involves the segregation of Zn–Mg zones coherent with the matrix which develop to dimensions of the order of 25 Å. × 50 Å. diameter, followed by the development of an intermediate, hexagonal precipitate which gradually loses coherency with the matrix. However, Guinier–Preston zone formation undoubtedly occurs in the early stages of high-temperature ageing as well, for such zones are readily developed during quenching and heating to the ageing temperature. If the above hypothesis is correct then the loss of resistivity in the early stages of high-temperature ageing must be ascribed to accelerated growth of the zones beyond critical dimensions and earlier development of intermediate precipitates which are not markedly coherent with the matrix.

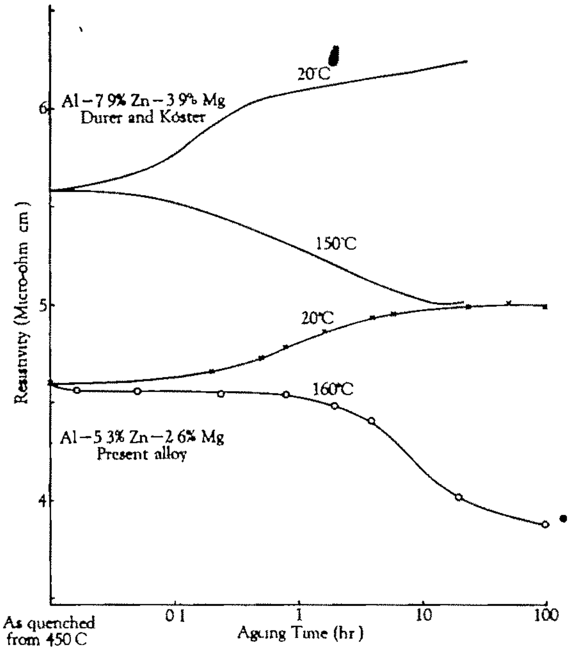

Fig. 1. Isothermal ageing Al–Zn–Mg alloys

Fig. 3 shows the profound effect of adding copper to an Al–Zn–Mg alloy of similar composition to that in Fig. 1. The ageing process is retarded and the resistivity changes are far more marked and persist to higher ageing temperatures. Single-crystal X-ray work on these alloys has shown that the Guinier–Preston

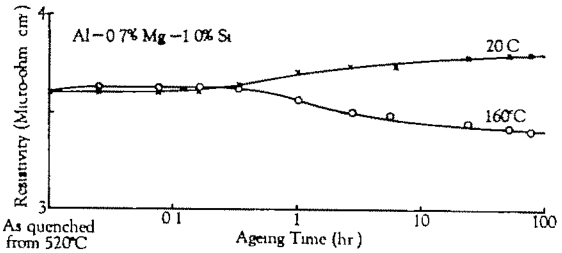

Fig. 2. Isothermal ageing Al–Mg–Si alloy

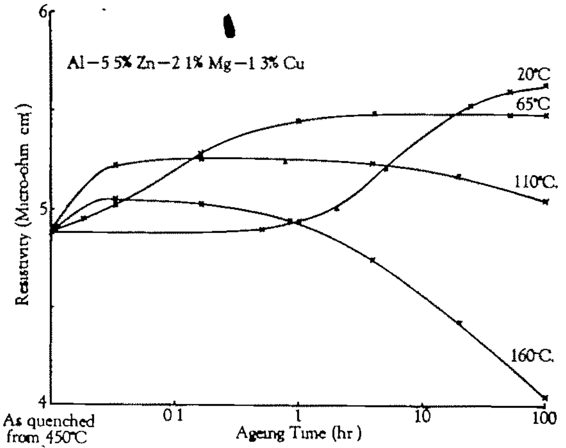

Fig. 8. Isothermal ageing Al–Zn–Mg–Cu alloy

zone structure once established is particularly stable and persists even during ageing at 160° C. and higher. The experimental evidence suggests that ideally the zone structure would not develop at ageing temperatures above 110° C., but in practice does so during heating to the ageing temperature (heating time less than 1 min.). For ageing temperatures of 110° C. and above the resistivity changes and mechanical properties of this alloy are significantly affected by the rate of heating to temperature, both peak hardness and peak resistivity being increased by slow heating.

For these higher ageing temperatures the resistivity peak is closely associated with the primary hardness increase, and it is reasonable to suppose that the resistivity effect is more closely associated with high coherency strains rather than with the existence of zones of critical dimensions. Thomas and Nutting[6] estimate that the zone diameter in this quaternary material is of the order of 80 Å.

Purification of Metals by Gas Chromatography

The use of chromatographic techniques for the separation of an alloy into its constituent elements or for the direct purification of metallic elements has not, to our knowledge, been reported. In order to test the feasibility of the separation a zinc–cadmium (8·4 per cent zinc) alloy was used. The advantages of this alloy system for this test are: (1) both elements have significant vapour pressures at temperatures which do not pose extremely difficult material problems; (2) they are chemically similar; (3) they are common metals; (4) their reactivity is small enough so that they pose no handling problems (as would the alkali metals).

The containing tube was a 50-cm. length of 13-mm. 'Vycor'. The stationary phase, lithium chloride, was supported as a film on sea sand (20 per cent lithium chloride, 80 per cent fine sea sand). The temperature was high enough so that the lithium chloride melted and formed a film on the sand. The eluting gas, purified helium, had a velocity of 150 ml./min. and was preheated to 620° C., the bed temperature. The 0·1-gm. sample of alloy was laid on top of the bed before heating. It was necessary to eliminate most of the oxygen and water from the system in order to minimize oxidation of the sample. The emerging metal vapours were caught on glass cold fingers held in the gas stream for a short time. The metal was dissolved in distilled nitric acid and analysed spectrographically.

It was shown that the cadmium content of the vapour was more than 200 times the zinc content. The amount of zinc present was near the lower limit of the analytical procedure. It was also shown, by duplicating the above experiment without the stationary or solid phases, that the process was not that of simple distillation. In this case the zinc deposit was equal to, or greater than, the cadmium deposit. Although neither of the constituents was collected quantitatively, these experiments suggest that metals can be efficiently separated.

I wish to acknowledge the assistance of Messrs. S. Greenberg and C. A. Youngdahl. This work was done under the auspices of the U.S. Atomic Energy Commission.

CHEMISTRY

Decomposition of Uranium Dioxide at its Melting Point

We have found that fusion of uranium dioxide in an argon arc furnace at 2,800 ± 100° C., between a tungsten cathode and a water-cooled copper anode, consistently gave lustrous grey metallic-looking products, with the gross analytical composition UO_{2-x} $(0 \cdot 15 > x > 0)$. The fused material was contaminated with less than 0·001 per cent of copper or tungsten. The extent to which the product was deficient in oxygen depended upon how long the sample had been held in the molten state, but the liquid seemed to approach a limiting composition, about $UO_{1 \cdot 88}$, after prolonged fusion. There was some vaporization from the melt, but the constitution of the vapour phase is unknown; after exposure to air, the powdery sublimate present in the furnace consisted of the oxygen-excess phase UO_{2+x}.

The massive fused material was quite stable in air, but when it was powdered it readily combined with oxygen, up to a composition around $UO_{2 \cdot 005}$. X-ray analysis of a fine chip of the fused product revealed the presence of two phases.

(*A*) The major phase (estimated 94–98 mole per cent) was face centred cubic with $a_0 = 5 \cdot 4718 \pm 0 \cdot 0004$ Å., which may be compared with the fluorite cell of essentially stoichiometric uranium dioxide, $UO_{1 \cdot 999 \pm 0 \cdot 001}$, with $a_0 = 5 \cdot 4700 \pm 0 \cdot 0004$ Å.

This small but significant expansion of the uranium dioxide lattice, which has also been observed when uranium metal and uranium dioxide are heated above 2,000° C. in a graphite resistance furnace[1], is taken to

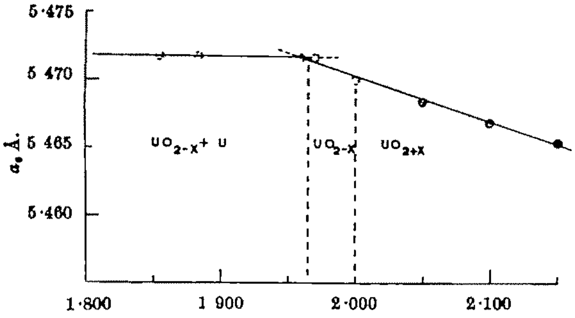

Fig. 1. ○, Ackermann's values

indicate that uranium metal is slightly soluble in uranium dioxide, that is, that the stoichiometric range of uranium dioxide extends slightly on the oxygen-deficient side of the ideal formula, at the quenching temperature of the arc furnace (estimated as between 2,500° C. and 1,600° C.). Extrapolating from the recent data of Ackermann[2] for the cell dimensions of oxygen-excess uranium oxides, it can be deduced that the limiting composition of the oxygen-deficient phase is $UO_{1\cdot 96}$ to $UO_{1\cdot 97}$ (Fig. 1).

(*B*) A minor phase was present to the estimated extent of 2–6 mole per cent. Its diffraction pattern consisted of seventeen lines, the *d* values of which are irreconcilable with the presence of any of the following phases: (*a*) the reported cubic lower oxides—uranium monoxide[3] with $a_0 = 4 \cdot 92$ Å., Zachariasen's supposed $UO_{1\cdot 75}$ (ref. 3) with $a_0 = 5 \cdot 477$ Å., or the UO_{2-x} of Perio and Hering[4] with $a_0 = 5 \cdot 484$ Å; or (*b*) the α- or γ-allotropes of uranium metal. α-Uranium, stable between room temperature and 667° C., is orthorhombic with *a* 2·852 *b* 5·865 *c* 5·495 Å. (refs. 2, 5); γ-uranium, stable above 767° C., is body centred cubic, $a_0 = 3 \cdot 43$ Å. (refs. 2, 3). However, the interplanar spacings agree fairly well with those of lines in the complex diffraction pattern[6] of β-uranium, the form stable only between 667° C. and 767° C. (Table 1).

Proof that the minor phase was uranium metal was afforded by the following experiment. One of the fused samples, of composition $UO_{1\cdot 883}$, was powdered and sealed into an X-ray capillary, both operations being carried out inside a sealed, evacuated apparatus. The X-ray pattern then showed that while the major phase was unchanged, the minor phase had altered; its diffraction pattern could be completely indexed in terms of the α-uranium structure (Table 2).

Thus uranium dioxide decomposes at its melting point, first to an oxygen-deficient oxide and then to metallic uranium (Fig. 1). Under the conditions of our experiments the metal, dispersed through the fused oxide, appeared to be retained in the highly metastable β-modification, but reverted to the stable α-uranium when the sample was ground up in the absence of oxygen.

Further work on the uranium–uranium dioxide system at high temperatures is being carried out and will be described elsewhere.

Two of us (J. O. S. and M. J. B.) wish to thank the Australian Atomic Energy Commission for research grants, during the tenure of which this work was carried out.

Electron Spin Resonance Absorption of the Biradical Molecular Complex, *p*-Phenylenediamine-chloranil

ACCORDING to Mulliken's quantum-mechanical theory the lowest state of a molecular complex *A.D*, where *A* and *D* stand for the electron acceptor and donor, respectively, is chiefly a non-bonding state, and the next excited state is a dative state $A^- – D^+$ (ref. 1). Kainer *et al.*[2–5] have considered the existence of molecular complexes where the ionic state is the lower of these two states and studied the electron spin resonance and the other properties of a number of

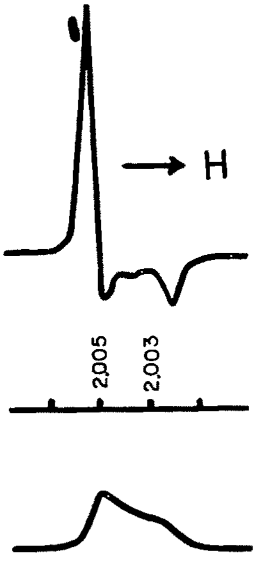

Fig. 1. Electron spin resonance absorption spectrum of the molecular complex *p*-phenylenediamine-chloranil

molecular complexes which consist of aromatic diamines and quinones.

It has been known that even in a biradical molecule of Chichibabin's hydrocarbon type, or its analogues, two unpaired electrons are only weakly coupled[6,7]. Therefore, it seemed that it might be possible to resolve the resonance absorption of aromatic diamine-halogenoquinone complexes because of a fairly large difference of *g*-value between these two components in ionized forms. With this hope we re-examined the electron spin resonance absorption of some aromatic diamine-halogenoquinone complexes using a high-resolution spectrometer[8]. The measurements were at a frequency of 9 kMc./s. and at room temperature.

Only in the case of *p*-phenylenediamine-chloranil was the resonance absorption clearly resolved and the two peaks were definitely correlated with the component ions. It was found that the shape of the resonance absorption curve depends, to some extent, on the preparation. A typical spectrum is shown in Fig. 1. The spectrum consists of a sharp peak with a *g*-value of 2·005 and a slightly broader one with 2·003. The former *g*-value is in good agreement with that of the potassium salt of tetrachloro-*p*-benzosemiquinone, 2 0048, and the latter with those of Wurster's blue salts, 2·0028 for the ferricyanide, and 2·0033 for the picrate[9]. The spectrum of N,N,N′,N′-tetramethyl-*p*-phenylenediamine-chloranil could not be well resolved but was found to be highly asymmetric. The main peak is again located at the position of tetrachloro-*p*-benzosemiquinone, but the slope at low magnetic field side is much steeper.

Our results seem to show that these molecular complexes, which we may call salts, consist of ionized components, and the electronic interaction between positively charged diamine and negatively charged quinone molecules is not strong. Both these molecular complexes are unstable. The colour of the latter sample changed from dark red to blue on standing for a week and its spin concentration decreased by a factor of ten. The same blue product could be obtained by mixing warm benzene solutions of the components. Tetrabromo-*p*-benzosemiquinone has a higher *g*-value than its chloro-analogue; however, the molecular compounds with bromanil gave absorptions which were too broad to be resolved.

We also detected a weak resonance absorption in *p,p*-diethoxybinaphthostilbene-chloranil[10]. It is not clear whether or not this molecular complex is of the ionic type like aromatic diamine-quinone.

The spin concentration in these aromatic diamine-quinone complexes has been found to be independent of temperature[3,5]. This property has not yet been well explained[5]. In connexion with this, it may be interesting to recall the observation that polycyclic aromatic hydrocarbon-iodine complexes, where the ground-state is supposed to be non-bonding, show strong electron spin resonance absorption[11]. No change of spin concentration in these molecular complexes was observed in the range from 77° K. to room temperature.

Spectrum of Delayed Fluorescence in Phenanthrene Vapour : a Criterion of Purity

In addition to the normal fluorescence emission with a decay constant of $\sim 10^8$ sec.$^{-1}$, a slow component with a decay constant of $\sim 10^3$ sec.$^{-1}$ has been detected by Dikun in the luminescence of phenanthrene vapour[1]. On the grounds that the spectra of both components are identical, Williams[2] has attributed this delay to the reversible formation of an excited dimer, from normal and electronically excited molecules, which has a life-time of the order of a millisecond.

In view of the remarkable similarity between the phenanthrene vapour emission spectra obtained by Dikun and the fluorescence spectrum of anthracene vapour, we decided to repeat this work using Eastman Kodak phenanthrene of 'highest purity, which was treated with maleic anhydride[3] until a saturated solution in hexane was completely transparent above 355 mμ ; this places an upper limit of one part in 25,000 on the concentration of anthracene impurity.

The phenanthrene vapour at 9·6 mm. and 260° C. was irradiated in a 'Pyrex' cell by the 313 mμ line isolated from a high-pressure mercury-vapour lamp by an alkaline chromate filter[4]. Emission spectra were photographed on a small Hilger quartz spectrograph, a locally constructed phosphoroscope being used to isolate the slow component ; a medium Hilger

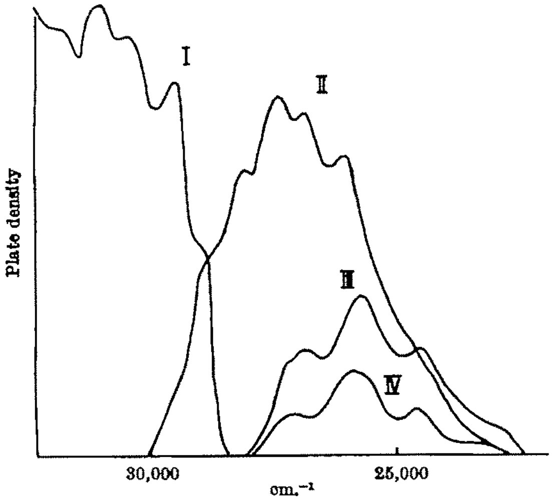

Fig. 1. Absorption (I) and emission (II) spectra of phenanthrene vapour at 9·5 mm. and 260° C. together with spectrum of delayed fluorescence (IV) and of pure anthracene vapour (III). Emission spectra were excited by the mercury 313 mμ line in each case

quartz instrument and hydrogen discharge lamp were used to photograph the absorption spectrum of the vapour at the same pressure and temperature.

Microdensitometer tracings of the plates obtained are shown in Fig. 1, together with the fluorescence spectrum of anthracene vapour excited by the 313 mμ line[5]. The delayed spectrum IV coincides in peak position and relative peak intensity with that obtained by Dikun and with the fluorescence spectrum of anthracene III; clearly it is not identical with the unsectored spectrum II and in so far as the fluorescence spectrum is a molecular characteristic it must be attributed to anthracene present as impurity.

If it is assumed that the anthracene in our phenanthrene sample is completely vapourized, its maximum possible pressure under the conditions described is $3{\cdot}8 \times 10^{-4}$ mm., corresponding to an optical density of $\sim 10^{-5}$ at 313 mμ. Thus collisional sensitization of anthracene by excited phenanthrene molecules is extremely unlikely, as is any mechanism involving the absorption of incident radiation by anthracene. We suggest, therefore, that anthracene is sensitized by collision by the excited phenanthrene dimer, which is simultaneously quenched; the lifetime of this dimer in the absence of anthracene is not known, but cannot be less than a millisecond, and in consequence the half-quenching pressure of anthracene required is at the most some 10^{-4} mm., which is within the estimated limit of impurity concentration. The absence of phenanthrene bands from the spectrum of the slow component IV suggests either that the excited dimer does not dissociate or that the quenching process is extremely efficient; this would be expected on the grounds of spin conservation since the excited dimer is in a singlet state[6].

A further requirement for efficient transfer concerns the coincidence of energy-levels in the donor and acceptor, and in this case affords an estimate of the maximum heat of formation E of the dimer from normal and excited molecules. Since the energy transferred is at least 26,400 cm.$^{-1}$ and the first excited singlet state of phenanthrene lies 28,300 cm.$^{-1}$ above the ground-state[7]:

$$E \leqslant 5{\cdot}4 \text{ kcal.}$$

which may be compared with the value ~ 6 kcal. for the heat of dissociation of the excited anthracene dimer found from the temperature dependence of self-quenching (ref. 8 and Stevens, B., and McCartin, P. J., unpublished work).

The marked resemblance between the unsectored phenanthrene spectrum presented by Dikun and the anthracene vapour fluorescence spectrum is indeed surprising. An optical density of 0·3 at 365 mμ quoted by this author suggests that the anthracene concentration in his sample is sufficient for its fluorescence spectrum to be excited directly, while the absence of phenanthrene bands could be due to complete self-quenching at the higher pressures used in his investigations.

Finally, it may be noted that if the proposed mechanism is correct, the delayed spectrum is virtually the molecular fluorescence spectrum of anthracene. This arises from a fortuitous combination of circumstances whereby a measurable fluorescence intensity of anthracene vapour at a concentration not exceeding 10^{-8} mol./l. is sensitized by an exceptionally long-lived species which is a secondary product of absorption in a region that does not overlap the emission spectrum of the acceptor.

We wish to thank the Safety in Mines Research Establishment for the loan of spectrographs, and one of us (E. H.) acknowledges the award of a maintenance grant from the Department of Scientific and Industrial Research.

BIOPHYSICS

Sedimentation of Deoxyribonucleic Acid isolated under Low Hydrodynamic Shear

Bacteriophage deoxyribonucleic acid in solution was recently demonstrated to be degraded by moderate hydrodynamic shear gradients[1]. This observation provoked the question whether the 6–8,000,000 molecular weight, usually observed in purified preparations of deoxyribonucleic acid from animal or bacterial sources, is in any way indicative of the size of the molecules of the acid in the living cell, since in none of the common methods used for purifying deoxyribonucleic acid are precautions taken to minimize shearing.

Anderson *et al.*[2] attributed to deoxyribonucleic acid the high, shear-labile viscosity they detected in strong salt solutions of nuclear material. Unfortunately, such solutions contain protein, which could cross-link deoxyribonucleic acid. This communication briefly reports the isolation from trout sperm of shear-sensitive purified deoxyribonucleic acid of high sedimentation coefficient.

Fish sperm were used because the nuclei contain no ribonucleic acid and are easily isolated by plasmolysis and centrifugation[3]. Mr. B. Hazen of the U.S. Fish and Wildlife Service, Nashua, New Hampshire, generously provided several samples of freshly shed milt.

A number of experiments, which will be described elsewhere, suggested that although disrupting a suspension of fresh sperm nuclei by sodium dodecyl sulphate[4] or strong salt produces an extraordinarily viscous solution, relatively little of the deoxyribonucleic acid is molecularly dispersed; instead, it appears likely that the deoxyribonucleic acid occurs in the form of extremely long, tangled molecules. To obtain deoxyribonucleic acid free of occluded protein it was necessary to degrade these long molecules by applying a small shearing force.

The following preparative technique was used: A dispersion of nuclei (about 0·1 mgm. nitrogen per ml.) in 0·01 *M* sodium chloride was mixed with 1/11 volume of 5 per cent sodium dodecyl sulphate in 45 per cent ethanol[4]. After standing for 1 hr. at room temperature the solution was passed twice through a 60-cm.-long glass capillary tube, applying a calculated mean shear of 800 sec.$^{-1}$. One-third volume of 4 *M* sodium chloride was added, and after gentle shaking for a further hour, the solution was centrifuged 1 hr. at 18,000*g*. Deoxyribonucleic acid (nitrogen/phosphorus ratio 1·70) was precipitated from the water-clear supernate by ethanol. About 25 per cent of the acid in the sperm was recovered. This presumably reflects the efficiency of dispersing the deoxyribonucleic acid; by applying higher shear forces to the solution the yield of acid increased, but the mean sedimentation coefficient of the product fell.

The secondary structure appeared to be intact since the deoxyribonucleic acid showed a 30 per cent hyperchromicity at 260 mμ on alkalination[5]. For physical study the deoxyribonucleic acid was redissolved in 0·01 *M* sodium chloride under gentle agitation.

The ultracentrifuge techniques have been previously described[1]. The cells were filled at a mean shear-rate of 1,000 sec.$^{-1}$. A typical distribution of the sedimentation coefficients in one of these preparations is shown in Fig. 1. The sedimentation diagram was unchanged after treatment with versene, trypsin, or chymotrypsin. Fig. 1*C* shows the corresponding distribution in deoxyribonucleic acid isolated from the same batch of milt by the method of Kay, Simmons, and Dounce[4].

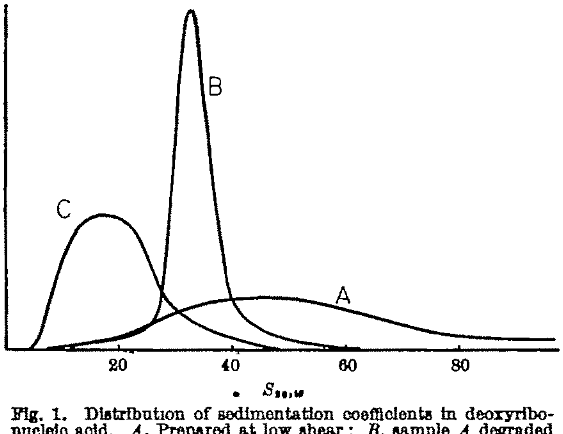

Fig. 1. Distribution of sedimentation coefficients in deoxyribonucleic acid. *A*, Prepared at low shear; *B*, sample *A* degraded by shear; *C*, prepared by method of Kay *et al.* (ref. 4). Solvent: 0·2 *M* sodium chloride, 0·015 *M* sodium citrate

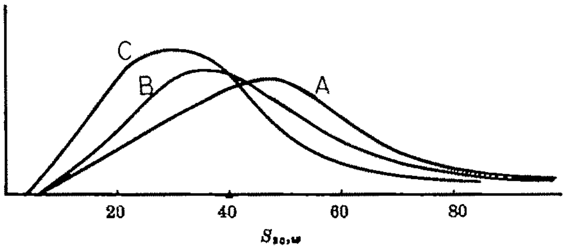

Fig. 2. Distribution of sedimentation coefficients in deoxyribonucleic acid. *A*, Intact; *B*, sheared once; *C*, sheared thrice. Solutions heated before centrifugation. Solvent: 0·2 *M* sodium chloride, 0·015 *M* sodium citrate. Ordinate scale twice that in Fig. 1

Deoxyribonucleic acid prepared in the manner outlined above and sheared at 40,000 sec.$^{-1}$ is shown in Fig. 1*B*. The shearing lowered the viscosity of the solution 25 per cent (as measured in a simple Ubbelohde viscometer at relatively high shear). When the solution was sheared twice more, the peak appeared even sharper, and the maximum dropped about 2 *S* (Svedberg units), while the viscosity dropped a further 10 per cent. Two anomalies are apparent in these results: (1) the viscosity changes are disproportionate to the drastic change in the sedimentation diagram on the first shearing, and the small change afterwards; (2) if the mechanism of the shear degradation is that previously discussed[1] the shearing should either halve the molecule or leave it intact, and it is unlikely that a drop from 32 *S* to 30 *S* represents a halving of the molecular weight.

However, the width of the sheared diagrams increased with dilution, and it appeared probable that the boundary was self-sharpened. This effect was not obviated at extreme dilution, but disappeared when the solutions were heated.

Briefly heating deoxyribonucleic acid solutions of moderate ionic strength to 100° C. destroys the ordered helical configuration of the molecule[6] and broadens the sedimentation distribution diagram[7], usually without decreasing the molecular weight. The broadening of the sedimentation diagram probably reflects an increased polydispersity of shape, together with some molecular degradation and some aggregation through re-formed hydrogen bonds[8]. Since it is unlikely that aggregation and degradation could fortuitously counterbalance if either process occurred to a great extent, it seems probable that at least the major features of the distribution of the sedimentation coefficients are preserved in the heated preparations.

Fig. 2 depicts the sedimentation diagrams of sheared deoxyribonucleic acid samples after heating. The fact that these distributions appear qualitatively consistent with the viscosity studies supports the suggestion that the diagrams approximate the molecular size distribution which was previously concealed in the hypersharp boundaries.

Under the brief shearing a fraction of the susceptible molecules escaped degradation each time. The only unexpected feature of the diagrams was a persistence of the 'tail' on the high *S* side. Since this material was not shear-labile, it might comprise aggregates of low asymmetry, possibly artefacts produced by the heating.

A number of observations indicated that self-sharpening occurs whenever the change of concentration (dc/dr) at a point within the boundary is sufficiently high. Thus, on shearing, the scission of the larger molecules increased dc/dr on the low *S* side of the boundary, giving rise to an artificial sharpness which over-emphasized the effect of the shearing.

In summary, it has been shown that deoxyribonucleic acid of unusually high sedimentation coefficient can be prepared. If these results can be extended to deoxyribonucleic acid from somatic tissues, it appears to me that at present no limit can be set to the length of the molecule of deoxyribonucleic acid *in vivo*. Protein bridges may exist along these 'molecules', but, until some evidence for them is forthcoming, it is simpler to imagine that the double helix persists uninterruptedly—perhaps for the length of a chromosome[9].

I am indebted to Prof. Francis O. Schmitt and Prof. Cyrus Levinthal for valuable discussions in the course of this work, and to Mrs. K. Y. Ho for technical assistance.

This work was aided by a grant (*E*-1469) from the National Institute of Allergy and Infectious Diseases, National Institutes of Health, U.S. Public Health Service.

Lubrication of Mammalian Joints

THE experiments and arguments of McCutchen[1] and Lewis and McCutchen[2] appear to confirm the theory of lubrication of mammalian joints first put forward twenty-seven years ago with particular reference to the intra-articular fibrocartilages and later developed in connexion with particular problems of articular structure, general and special[3]. The essence of that theory is that there is a sensibly thick film of synovial fluid between articular surfaces while the joint is in motion, and that this fluid is not only maintained between the surfaces but also flows between them in the direction of motion in accordance with the laws of viscous hydrodynamics. The question of the origin of the fluid was left in abeyance, being a physiological rather than a mechanical problem.

It is an axiom, too often unstated, that the flow of lubricant film while it is acting requires that the fluid shall adhere to the fixed and the moving surfaces; this is tantamount to saying that these surfaces shall be thoroughly soaked with fluid. Movement of one of the surfaces will then necessarily produce a laminar flow if the fluid be viscous, as is easily demonstrated by simple physical models at speeds commensurate with those found in our joints. The structural basis for the sponge-like character of articular cartilage has already been shown by myself[4]. This structure differs markedly from that described by Benninghoff, referred to in the communication from Lewis and McCutchen. The late Prof. Benninghoff told me verbally that he had not examined articular cartilage by the methods given in the preceding reference. Lewis and McCutchen have shown that the articular sponge not only soaks up fluid, thus ensuring its adhesion to the bearing surfaces, but also permits it to be squeezed out, thus ensuring an instantaneous formation of a lubricant film which can then itself be moved as stated above. Such a rapid formation of lubricant fluid is essential in the joints where the range of movement is small by engineering standards and also alternates rapidly in direction. It should be stressed, however, that any theory of articular lubrication must cover all the phenomena of structure within the joint cavity, and should account for the presence, shape and disposition of soft structures (for example, fatty pads) and ancillary deformable structures (for example, articular disks) found in certain joints where the general theory of viscous lubrication indicates a need for their presence. The 'weeping lubrication' spoken of by Lewis and McCutchen appears to complete the existing theory rather than to supplant it, and is a valuable addition to our knowledge of biomechanics.

[4] MacConaill, M. A., *J. Bone and Jt. Surg.*, **33**, B, 251 (1951).

WHILE we agree with Prof. MacConaill that there is a thick layer of fluid over most of the area between the articulating surfaces of a joint, we none the less insist that how it gets there is a mechanical rather than a physiological problem. When a joint is loaded, the fluid between the surfaces will be at high pressure, and this must be overcome by whatever process supplies the fluid. Weeping lubrication solves the problem by automatically pressurizing the reservoir from which the fluid is supplied. This is accomplished at the expense of gentle contact at a few high spots in order to press the sponge-like cartilages back into the fluid they are soaked with.

Hydrodynamic lubrication can, in principle, drag fluid into the high-pressure region, but the amount is very small. A simple calculation[1,2] for the knee joint of a sheep shows that, even were the shapes and motion of the joint surfaces ideal, the amount of fluid which can be brought between the articulating surfaces in one swing of the leg at walking speed is equivalent to a layer no greater than half a micron thick. We have shown that the weeping process can provide 30–70 times this amount of fluid; so it seems unlikely that the hydrodynamic contribution is very important. At lower speeds, hydrodynamic lubrication seems even less likely, because the amount of fluid supplied per swing follows the half-power of the sliding speed. If one follows the hydrodynamic theory down to extremely low sliding velocities in the hope of being helped by the unusual properties of synovial fluid[3], one finds that there is no appreciable increase in viscosity of the lubricant until the sheep walks at less than 10^{-7} m.p.h., at which speed the lubricating film is less than 10 Å. thick. Few surfaces are this smooth, and in practice, boundary lubrication conditions would set in at far higher speeds.

Failure of the lubricant film at low sliding speeds, which is a standard feature of hydrodynamic lubrication[3], ought to lead to a high coefficient of starting friction. Charnley[4] actually measured starting friction and found that no more force was required to start a joint sliding than to keep it sliding.

The precise structure of the cartilage is not of prime importance. What is important is that it should act as a sponge in which fluid can move easily in a direction normal to the articular surface; that this does occur is confirmed by the experiments detailed in the second half of our original communication. It is also important that the lateral permeability should not be too high, otherwise the cartilage would rapidly collapse when the load was applied. Our experiments gave no indication of a high lateral permeability, but this aspect of our hypothesis does require more detailed, preferably quantitative, study.

BIOCHEMISTRY

Preparation and Some Properties of a Soluble Ribonucleic Acid in Yeast

The function of soluble ribonucleic acid in the transfer of activated amino-acids to the microsomal ribonucleoprotein particles has been correlated to the presence of a specific terminal *–pCpCpA* group[1–3], and the occurrence of pseudouridylic acid in the molecules[4]. One of the basic requirements for the full understanding of the structural basis of the function of soluble ribonucleic acid would be the preparation of a ribonucleic acid sample which is homogeneous, unaltered, and having a functional activity not different from that present in the living cells. The principal purpose of this study has been to establish the technique whereby a sample of acid which satisfies the above requirements is prepared. The attempt towards this direction led to preparation of an active ribonucleic acid sample which is homogeneous when judged by electrophoretic examination and sedimentation analyses

It has been reported that in yeast cells the bulk of the active ribonucleic acid is localized in the fraction soluble at *p*H 5·0 or *p*H 5·3 of the 105,000*g* supernatant of the homogenate[4]. A crude sample of the acid obtained by the phenol method of Kirby[5] from the *p*H 5·0 supernatant fraction was contaminated with polysaccharide which has, however, little effect on the incorporation of leucine labelled with carbon-14 into the ribonucleic acid under the conditions previously described[4]. The sample of crude acid was dissolved in 0·001 *M* potassium phosphate buffer at *p*H 7·1, and shaken with 'Ecteola'-cellulose[6] for 5 min. in the cold. About 90 per cent of ultra-violet-absorbing substance originally present in the crude ribonucleic acid preparation was adsorbed on 'Ecteola', whereas all polysaccharides remained uncombined. The 'Ecteola'–ribonucleic acid complex was thoroughly washed with the buffer to remove the unadsorbed materials. The bulk of the ultra-violet-absorbing substance could then be released with 0·3 *M* sodium perchlorate at *p*H 7·1, and recovered by ethanol precipitation. Under these conditions, the ribonucleic acid prepared from the cytoplasmic ribonucleoprotein particles was held firmly to 'Ecteola' and did not come out with 0·3 *M* sodium perchlorate. About 75 per cent of ultra-violet-absorbing substance in the original crude sample of ribonucleic acid was recovered by precipitation by ethanol. Electrophoretic examination revealed the removal of polysaccharides. However, a small peak was detectable slightly ahead of the main acid peak. This fast component was removed completely by 24-hr. dialysis. An electrophoretically homogeneous sample of a soluble ribonucleic acid could thus be obtained. A rapid 'Ecteola' treatment seems to be essential for the successful preparation. An extensive degradation and inactivation of the ribonucleic acid were observed, when the column chromatographic fractionation on 'Ecteola' of the ribonucleic acid was tried.

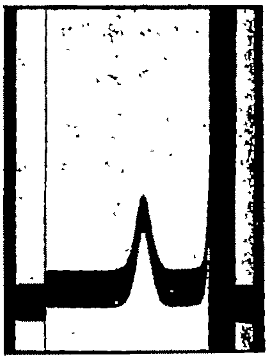

Fig. 1. Sedimentation pattern of purified yeast soluble ribonucleic acid. Picture taken after 24 min. at 56,900 rev./min. in a synthetic boundary cell. 1 6 per cent solution in 0·1 *M* sodium chloride–0·03 *M tris*(hydroxymethyl)aminomethane at *p*H 7 1

The purified sample was also homogeneous in the sedimentation analyses (Fig. 1), giving a sedimentation constant of $S^{0}_{20} = 4\cdot0$, extrapolated from the values obtained at three sample concentrations in 0·1 *M*

sodium chloride – 0·03 *M tris*(hydroxymethyl)-aminomethane at *p*H 7·1. The molecular weight of the ribonucleic acid calculated from the sedimentation constant and the intrinsic viscosity ($[\eta]_{20}$ = 0·05) was 27,000 (Table 1). The nitrogen/phosphorus ratio of the product was 1·63. Contamination of deoxyribonucleic acid in the most purified sample was around 0·25 per cent relative to ribonucleic acid.

The nucleotide composition analyses by 'Dowex-1' column chromatography[7] confirmed the previous findings of the predominant localization in the soluble ribonucleic acid of pseudouridylic acid[4,8] and other minor nucleotide components[8].

The purified ribonucleic acid combined L-leucine in the proportion of 2·86 mμM/mgm. ribonucleic acid under the conditions described previously[4]. The value was about 40 per cent higher than that obtained when the crude sample of ribonucleic acid was tested. This seems to be not due to the inhibitory action of contaminated materials in the crude acid, but rather to the removal of inactive ultra-violet-absorbing substances during the purification.

Although the ribonucleic acid obtained is fairly homogeneous from the criteria here adopted, it is not known at the present time whether the acid is a mixture of ribonucleic acids each of which is specific for the attachment of individual amino-acids[9].

A full account of this work will be published later.

Biosynthesis of Chlorophylls a and *b* in *Chlorella vulgaris*

WE have shown that both carbon atoms of glycine were incorporated into chlorophyll *a* when *Chlorella vulgaris* was incubated with ^{14}C-glycine for a period of 1 hr. During this period no carbon-14 from the carboxyl group could be detected in chlorophyll *b*, whereas the incorporation of the carbon from the methylene group was several times higher than in the case of chlorophyll *a*. Only after longer periods of incubation with 1-^{14}C-glycine was the isotope found in chlorophyll *b* as well.

The purity of the glycine samples (1-^{14}C-glycine and 2-^{14}C-glycine, specific activities about 50 μc. per mgm.) was determined chromatographically; the radioautograms contained no impurities. *Chlorella vulgaris*, strain '211/11*m*' or 'Cornell 11' (received from the Culture Collection of Algae and Protozoa, University of Cambridge), was grown in sterile liquid cultures in volumes of 100 ml. per flask. The composition and the preparation of the medium were described by Della Rosa *et al.*[1]. In order to obtain a homogeneous algal culture of the 'D_A type'[2], the Tamiya procedure of 'synchronous culture' has been adopted (16 hr. light of 1 k.lux and 8 hr. of darkness). After maximal verdancy of the cells was achieved, 10 μc. ^{14}C-glycine were introduced. Samples were then withdrawn after various periods of incubation under 1 k.lux of light. The yield per flask amounted to about 100–150 mgm. of dry algae. 'Raw chlorophyll', free of xanthophylls, was extracted from the frozen material according to Strain and Manning[3] and chromatographed on Whatman No. 1 paper impregnated with saccharose (Sporer *et al.*[4]) using Bauer's solvent[5]. Chlorophylls *a* (R_F about 0·65) and *b* (R_F about 0·35) were eluted with ethyl ether and determined spectrophotometrically, employing the absorption coefficients given by Smith and Benitez[6]. The wet combustion of the chlorophyll samples was carried out as described by Van Slyke and Folch[7], using inactive glucose as carrier, and the carbon dioxide converted into barium carbonate. The labelled carbon dioxide set free from the barium carbonate was measured in the gas Geiger counter of Broda *et al.*[8] and calculated to 100 per cent counting yield. The results are presented in Table 1.

Table 1. INCORPORATION OF CARBON-14 FROM GLYCINE INTO CHLOROPHYLLS *a* AND *b*

Substrate	Time of incubation (hr.)	Specific activity of chlorophyll (c.p.m. × 10^{-4} per mgm. C)					
		a			*b*		
		No.	Results	Average	No.	Results	Average
1-^{14}C-glycine	1	I	1·29	1·02	I	0	0
		II	0·91		II	0	
		III	0·85		III	0	
	6	I	4·96	5·25	I	5·36	6·16
		II	5·17		II	6·71	
		III	5·62		III	6·43

		II	6·55		II	9·72	
		III	12·8		III	—	

Della Rosa *et al.*[1] found in experiments in which the period of incubation lasted several days that, in contrast to the biosynthesis of hæm, not only the methylene carbon but also the carboxyl carbon of glycine is utilized in the synthesis of chlorophylls *a* and *b*. In view of the fact that the isotope concentrations in both chlorophylls were of the same order of magnitude they decided against the current theory that chlorophyll *b* may be derived from chlorophyll *a*. Since our results after 6 hr. of incubation are similar to those of Della Rosa *et al.*, and since after 1 hr. of incubation (that is to say, in the beginning stages of biosynthesis) the uptake of carbon-14 from the two sources is different for the two chlorophylls, the suggestion that the path of biosynthesis of chlorophylls *a* and *b* may be different seems quite reasonable.

It would appear from our work that in the biosynthesis of chlorophyll *b*, as in the synthesis of hæm, the methylene carbon of glycine plays the main part, and that this process may be simpler or quicker than the incorporation of this carbon into chlorophyll *a*. On the other hand, both carbon atoms are utilized equally well by chlorophyll *a*. The scheme proposed by Della Rosa *et al.*, namely, that the carboxyl carbon is incorporated into the chlorophylls via the citric acid cycle, cannot be accepted, as in this case the carbon-14 concentration in chlorophylls *a* and *b* after 1 hr. of incubation should be of similar magnitude. As can be seen from Table 1, there is considerable incorporation of the carboxyl carbon into chlorophyll *a* and no incorporation at all into chlorophyll *b* after 1 hr. of incubation.

After 6 hr. the specific activities of both chlorophylls are of the same order, and are always higher on incubation with 2-^{14}C-glycine than with 1-^{14}C-glycine. This observation may suggest some incorporation of the carboxyl carbon of glycine, which takes no direct part in the biosynthesis of chlorophyll *b*, into some other group which may then be equally well used in the synthesis of both chlorophylls.

We are indebted to Prof. E. Broda in Vienna, where our work was started, and to Prof. I. Reifer in Warsaw, where our work was concluded, for helpful discussions.

Stereospecificity of Enzymic Reactions involving Mevalonic Acid

MOST of the biosynthetic studies with mevalonic acid have so far been carried out with the racemic substance labelled with carbon-14. There have been no reports indicating a utilization greater than 50 per cent of DL-mevalonate either *in vivo* or *in vitro* in any enzymic reaction. Thus, Tavormina, Gibbs and Huff[1], who made the discovery that mevalonate was an outstanding precursor of cholesterol, noted that about 43 per cent of the DL-[2-^{14}C] mevalonate was converted in liver homogenates into cholesterol; an observation confirmed by Popják *et al.*[2]. Gould and Popják[3] found that of the dose of carbon-14 contained in DL-[2-^{14}C] mevalonate and injected into mice about 40 per cent appeared in body sterol, 10 per cent in expired carbon dioxide and 50 per cent in the urine. Both Tchen[4] and Levy and Popjak[5,6] observed that in the mevalonic kinase reaction, in the phosphorylation of mevalonate with adenosine triphosphate to 5-phosphomevalonate, no more than 50 per cent of the DL-mevalonate was used by the enzyme. All these observations led to the conclusion that only one enantiomorph of mevalonate could act as substrate in biosynthetic reactions, and this was assumed to be the natural (+) isomer, $[\alpha]^{24}_{D}$, + 10° (Wolf *et al.*[7]).

We have obtained direct evidence on this question and found that the mevalonate excreted in the urine of animals given DL-mevalonate is of the unnatural optical configuration, and that the 5-phosphomevalonate, prepared enzymically with liver mevalonic kinase[5,6] was an optically active substance.

Three rats, kept in metabolism cages, were given daily in their food 50–100 μmoles of potassium DL-mevalonate mixed with a small amount of DL-[2-^{14}C] mevalonate. The total dose given to the three animals was 201 mgm. (calculated as mevalonic acid lactone). The urine, which was collected and pooled, was brought to *p*H 9 and extracted with chloroform for 20 hr. to remove neutral material; then it was made acid to congo red and extracted again for 20 hr. with chloroform. Nearly all the carbon-14 contained in the urine was recovered in this extract. The second chloroform extract was evaporated under vacuum and the residue distributed between water and ether. The aqueous layer was evaporated to dryness under reduced pressure at 30–40° and the residue distilled at 0·001 mm. of mercury pressure, the bath temperature being raised to 130°. The distillate (105 mgm.) was refluxed with diphenylmethylamine in benzene for 1½ hr. and mevalonic acid diphenylamide (149 mgm.) isolated as described previously[8]. On recrystallization from benzene, 105 mgm. of the amide (m.p. 95–96°) were obtained with $[\alpha]^{24}_{589}$ + 2·2° in ethanol. The results of optical rotatory dispersion measurements, made at a concentration of 1·2 gm./100 ml. in ethanol, are shown in Fig. 1.

Wolf *et al.*[7] gave $[\alpha]^{24}_{D}$ − 2·0° (in ethanol) for the diphenylamide of mevalonic acid lactone isolated from distillers' solubles. It is apparent from the results that the rats have utilized the natural and excreted the unnatural isomer of mevalonic acid.

5-Phosphomevalonate was prepared, as the barium salt, from DL-mevalonate with liver mevalonic kinase according to the procedure of Levy and Popják[6]. Optical rotatory dispersion measurements were made on an aqueous solution (0·25 gm./100 ml.) of 5-phosphomevalonic acid (after removal of barium); these results are shown in Fig. 2. The specific rotation at 589 mμ was $[\alpha]^{24}_{589}$ − 6·1° and the molecular rotation $[M]^{24}_{589}$ − 13·9°. These observations leave no doubt that the former assumptions as to the specificity of

Glucose-isomerase in Barley Malt

WORK in this Institute on the enzymatic breakdown of starch has included above all the qualitative and quantitative determination of products resulting from this breakdown[1]. We have observed that in every case fructose occurred beside the glucose derivatives already in the barley malt extract[2]. The presence of glucose may be attributed to the activity of the amylo-glucosidase enzyme of the barley malt. Among the glucose derivatives maltose is produced by the activity of the well-known β-amylase. The oligosaccharides, from which we succeeded in identifying altogether eight members in two homologous series, beginning with maltotriose and finishing with malto-octaose, were produced by the activity of the amylase. Besides the amylolytic enzymes, there must also be a glucose-isomerase enzyme in action, and it must be its effect which results in the appearance of fructose.

We have verified the presence of fructose by paper chromatography. Fructose is well characterized by the lemon-coloured spot formed in *p*-amino-phenol[3] used as detecting agent. This spot appears only when fructose is present. Among the other carbohydrate products yielded by the breakdown of starch, maltose gives in *p*-amino-phenol an ochre-yellow spot while the oligosaccharides produce spots in colours ranging from reddish yellow to reddish brown. Very characteristic are further for fructose the R_F and R_G values respectively, which could be exactly determined by the control test. In this way the presence of fructose was undoubtedly proved. The quantity of fructose introduced by the malt-extract, and the fructose and saccharose content of the raw material were exactly determined, and it could be observed that at the end of the saccharification process the reaction-mixture contained an amount of fructose which was two or three times higher than that of the raw material. This could be observed no matter whether pure starch of some starch-containing raw material (potatoes or corn) had been chosen for the saccharification. This cannot occur except in the case when, during the breakdown of the starch, enzyme action transforms glucose into fructose. The presence of such an enzyme was proved experimentally; thus we treated a 5 per cent glucose solution with barley malt extract and found that during the reaction the amount of glucose decreased while that of the fructose increased.

We treated a 13–17 days-old malt germinated on a threshing floor with a 5 per cent solution of analytical glucose at 55° C. and 5·2 *p*H, during 2 hr. The carbohydrates were quantitatively determined in both solutions before mixing and in the reaction products after the treatment, using paper chromatography.

The results obtained by quantitative analysis of the chromatogram spots are given in Table 1, every result being for 150 ml. of the solutions.

Table 1

Colour of the spot	$R_F \times 100$	Identified quality of the spot	1*	2† (gm.)	3‡
Lemon-yellow	26 8	Fructose	—	0·76	0·23
Dark brown	24·0	Glucose	4·6	3·92	0 26
Light brown	18·6	Saccharose	—	0·06	0 06
Ochre-brown	15 2	Maltose	—	0 78	0·68
Reddish-brown	11·7	Maltotriose	0 2	0 40	0·36
Yellowish-brown	—	Oligosaccharides	—	0 52	0·58
Brown	—	Dextrins	—	0 92	0·81
		Totals	4·8	7·45	2·98

* Mixture of 100 ml. 5 per cent glucose solution and 50 ml. distilled water.

† 100 ml. 5 per cent glucose solution and 50 ml. barley malt extract.

‡ Mixture of barley malt extract and 100 ml. distilled water has been chromatographed and analysed.

These results show that, due to the barley malt extract, a quantity of about 1 gm. disappeared from the glucose in solution while the amount of the fructose increased by about 0·5 gm.

Thanks are due to Mrs. Agnes Osztróvszky and Miss Eva Gábor for their kind assistance.

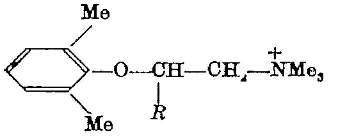
ANIMAL PHYSIOLOGY

Powerful Adrenergic Neurone-blocking Agents related to Choline 2,6-Xylyl Ether Bromide

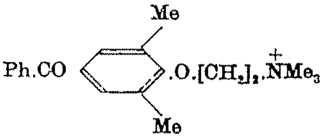
THE discovery that the functioning of the post-ganglionic sympathetic adrenergic nerves could be impaired by choline 2,6-xylyl ether bromide (I), *TM* 10 (refs. 1, 2), led to a search for compounds having a similar effect, but lacking the parasympathomimetic actions which preclude its use in man[3]. Such a selective blocking action was found in a series of benzyl quaternary ammonium salts[4], and one of these, bretylium tosylate, was eventually shown to be a valuable antihypertensive agent in man[5]. This compound can depress conduction in various nerves, and the specificity of its blocking effect on the sympathetic nervous system seems to be related to its selective accumulation in adrenergic neurones (unpublished work).

Investigation of analogues of choline 2,6-xylyl ether bromide showed that the β-methyl substituted compound (II) had a similar but more specific action on the adrenergic nerve mechanism[6]. We also have prepared many compounds related to *TM* 10 and screened them for adrenergic neurone-blocking action in the cat, by their ability to relax the nictitating membrane without causing mydriasis. We have found that additional substitution of *TM* 10 in the 4-position by ethoxycarbonyl, acetyl or benzoyl, leads to reduction or abolition of the gross parasympathomimetic effects, with retention or enhancement of the antiadrenergic properties.

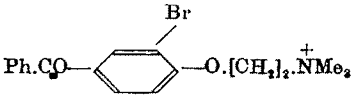
One of the most active of these compounds, 172*C*58, is 10–20 times more active than *TM* 10 and is virtually devoid of parasympathomimetic properties. The corresponding bromo-analogue, 225*C*59, has similar adrenergic neurone-blocking properties, but produces muscarine-like effects at high dose-levels. Many chemical variations on the compound 172*C*58, which included branching or lengthening the chain, additional substitution or hydrogenation of the 4-benzoyl group and several variations of the groups in the 2- and 6-positions and in the cationic head, have led to lower activities. Related compounds are being investigated.



I, *R*=H, II, *R*=Me



172*C*58*



225*C*59*

* Patents pending

We examined 172*C*58, as its bromide, by the same methods as were used with bretylium[7]. In cats, intravenous doses of 0·05–0·5 mgm./kgm. rapidly depressed for several hours the responses to stimulation of various adrenergic nerves; for example, the increase in heart-rate caused by stimulation of the inferior cardiac nerve, the relaxation of the uterus caused by stimulation of the hypogastric nerve and the contraction of the nictitating membrane during stimulation of the postganglionic cervical sympathetic trunk. These doses lowered the blood pressure of cats in the supine position and caused marked postural hypotension. These effects occurred without depression of the responses to injected noradrenaline or adrenaline; indeed their actions were enhanced, as occurs after sympathectomy. Sweating caused by sympathetic nerve stimulation in the cat was not abolished. Since the postganglionic fibres to the sweat glands are cholinergic, this suggests that the action of the compound is largely confined to adrenergic neurones. The compound showed weak and transient ganglion-blocking properties. No blocking action on the mechanism for release of pressor amines from the adrenals was detected in acute experiments. Neuromuscular paralysis of voluntary muscle occurred with doses about 50 times greater than those which affected the adrenergic nerve mechanism.

The distribution in the tissues of the drug labelled with carbon-14 on one of the quaternary methyl groups showed that it had a high affinity for the adrenergic neurones. 2 hr. after the injection of 1 mgm./kgm. subcutaneously in the cat, the radioactivity in sympathetic ganglia and adrenergic nerve trunks indicated the presence of concentrations of approximately 0·005 and 0·002 μmole/gm., respectively—some five times the highest found in other ganglia and nerves. Furthermore, when the drug was applied topically to adrenergic nerves between stimulating electrodes and a suitable end-organ, the response of the latter was abolished. This was shown in tests using the hypogastric nerve, and the sympathetic fibres of the greater auricular and mesenteric nerves in the rabbit, and also on the postganglionic cervical sympathetic and inferior cardiac nerves of the cat. Like bretylium, the drug has a long-lasting local anæsthetic action. We tentatively conclude that it may impair conduction in those neurones to which it gains access, and that its selectivity of action on adrenergic neurones may be related to its accumulation in these neurones.

The effects of 172*C*58 resemble those of bretylium but are more powerful. However, there are important qualitative differences. The adrenergic neurone-blocking action of 172*C*58 is considerably more rapid in onset and ends sooner, whether the drug is given by intravenous or subcutaneous injection. A related feature is its more rapid effect on isolated nerve-muscle preparations, from which, unlike bretylium, it may be readily removed by washing. Another major difference is that 172*C*58 caused no sympathomimetic effects in cats, except when several times the adrenergic neurone-blocking dose was given.

In two subjects given the drug intravenously and in two hypertensive patients given oral doses, 172*C*58 seemed a less active hypotensive agent than bretylium (Laurence, D. R., Moulton, R., and Rosenheim, M. L., personal communication). Its main value would seem to be as a pharmacological tool, its advantages over bretylium being its more rapid and more readily reversible action and its freedom from sympathomimetic properties.

Significance of Adipose Tissue Lipoprotein Lipase

THE post-heparin clearing factor in plasma has the same properties as tissue lipoprotein lipase; this is explained by Korn[1] by the fact that by the action of heparin lipoprotein lipase is released from the tissues in the blood stream. The greatest amount of lipoprotein lipase was found in adipose tissue[2]. A number of observations suggest indirectly the possible physiological significance of this enzyme in adipose tissue, particularly during the mobilization of fat from depots[3–7]. We have tried to elucidate the significance of adipose tissue lipoprotein lipase in rats by investigating the changes of its activity (*a*) after the administration of heparin and (*b*) during the mobilization and deposition of fat.

Immediately after killing the animal we removed the fat of the epididymis, froze it by means of liquid air, ground it to a fine powder from which we removed the fat in the cold, using acetone and ether, and afterwards dried it. The homogeneous powder was extracted with a solution of ammonia, *p*H 8·5, and the activity of lipoprotein lipase was estimated by determining the non-esterified fatty acids, using Dole's method[9], liberated during incubation with an activated artificial oil emulsion 'Ediol'[8] as a substrate (0·5 ml. extract: 2·5 ml. emulsion, temperature 37° C., incubation period 30 min.) and was expressed per 100 mgm. of dried tissue powder. 1 *M* sodium chloride, which is a specific inhibitor of lipoprotein lipase, inhibited esterolysis; this we consider evidence that in our experiments we actually estimate the enzyme.

The administration of heparin 'Novo' (500 μ/kgm. body-weight intraperitoneally), which causes a marked lipolytic activity of the blood, leads to a marked decrease ($P = 0{\cdot}05–0{\cdot}02$) of the lipoprotein lipase activity (Table 1, lines 1, 2). In a further series of experiments we determined the activity of lipoprotein lipase in adipose tissue of rats which had been fasted for 24 hr., and in similarly fasted rats with alloxan diabetes 2, 4 and 6 weeks after the administration of alloxan. No insulin was administered 48 hr. before the experiment. Under these conditions a marked mobilization of fat occurs. For comparison the activity in normal non-fasted animals and in animals which after 48 hr. fasting were re-fed for 20 hr. (Larsen mixture, glucose solution) was determined. In this case fat is not mobilized and in re-fed animals its deposition is much enhanced[10]. Table 1, lines 3 and 4, record the difference in the activity in rats fasting for 48 hr. and in re-fed rats. Fig. 1 summarizes the results of the entire series of experiments in relative figures. It is evident that under conditions when fat is mobilized the activity of lipoprotein lipase in adipose tissue is markedly reduced as compared with the activity in fed animals. Under the condition of an accentuated formation of depot fat in re-fed animals the activity is on the contrary markedly higher as compared with fed animals.

Table 1. RELEASE OF NON-ESTERIFIED FATTY ACIDS FROM THE SUBSTRATE

	No. of rats	No. of samples†	Microequivalent of non-esterified fatty acid ± S.E.	Statistical significance
1* Saline i.p.	15	5	29·02 ± 2 69	$P < 0{\cdot}05$
2* Heparin i.p. 500 μ/kgm.	15	5	21·88 ± 0 94	$P > 0{\cdot}02$
3 48 hr. fasting	18	6	6 32 ± 0·70	$P < 0{\cdot}001$
4 Refeeding	15	5	23·4 ± 3·19	

* Rats in experiments 1 and 2 had free access to food before being killed.

† Every sample was obtained by pooling adipose tissue from three animals.

We assume that in agreement with Korn's concept, which has been confirmed also by other authors[11,14], we can take the decrease of activity in the extract after the administration of heparin as a consequence of the liberation of lipoprotein lipase from adipose tissue. The high enzyme activity during fat deposition, contrary to the low activity during fat mobilization, is striking. The few papers published hitherto on the lipolytic activity of adipose tissue[12,13] do not reveal this fact. This can be explained by the use of a method which is not specific for the estimation of lipoprotein lipase[12]. Only Hollenberg's communication[14], which was published at a time when our work had been already completed and prepared for the press, has arrived at similar results though by a different approach.

As a result of our findings we may conclude, though it is only speculation so far, that during the formation

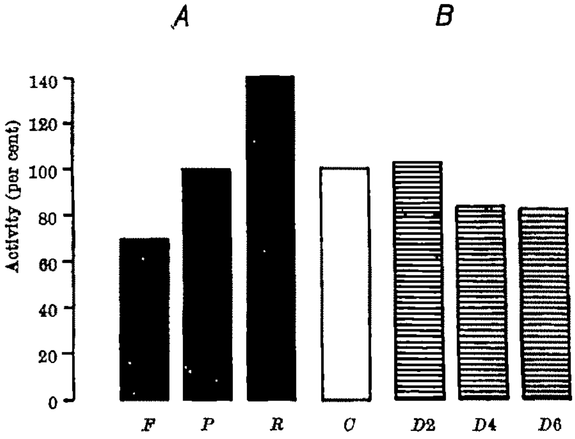

Fig. 1. Lipoprotein lipase activity of epididymal adipose tissue (*A*). *F*, decreased activity during fasting; *P*, 100 per cent activity in the post-absorptive state; *R*, increased activity after re-feeding. (*B*). *C*, 100 per cent activity of 24-h. fasted control rats; *D*2, *D*4, *D*6, diabetic rats, 2, 4 and 6 weeks, respectively, after administration of alloxan. Rats fasted 24 hr.

of fat in adipose tissue lipoprotein lipase is either synthesized or its activity is enhanced, which would suggest that this enzyme participates in the formation of fat depots. The finding of a reduced activity during fat mobilization must not be taken as evidence that lipoprotein lipase does not participate in this process. It is possible that during this process this enzyme is liberated by adipose tissue, just as after the administration of heparin—but much more slowly—to be transported to another site in the organism where its action is necessary.

Metabolism of Bemegride labelled with Carbon-14

Bemegride (β-ethyl β-methyl glutarimide), labelled with carbon-14 in both the α positions, is excreted largely in the urine and to a lesser extent in the bile and fæces when administered to mice, rats and guinea pigs[1]. Chromatograms of urine and bile from these animals were developed by the ascending technique using *n*-butanol/acetic acid/water (12 : 3 : 5, v/v). Autoradiographs of chromatograms of guinea pig bile showed only one spot (R_F 0·88) which was identical in mobility to the control-labelled bemegride. The urine of rats, collected 15–120 min. after administration of labelled bemegride, revealed two spots of R_F values 0·88–0·89 and 0·77–0·81. The faster moving fraction moved as one spot when labelled bemegride was added to the urine before chromatography. The spot with the lower mobility increased in intensity over the 15–120 min. period of urine collection. Urine from mice, 15–120 min. after bemegride injection, showed two spots with R_F values similar to those of rat urine, while urine collected 8 hr. after injection revealed a third spot of R_F 0·40–0·46. This spot became progressively more intense and the faster moving fractions correspondingly less up to 24 hr.

Bemegride labelled with carbon-14 was incubated with rat liver slices in Krebs–Ringer-phosphate solution for 5 hr. at 37° C. and two radioactive spots were revealed on chromatography of the liquid medium. The R_F values, 0·88 and 0·80, corresponded to those obtained from rat urine, suggesting that the liver is the site of bemegride metabolism *in vivo*.

Partition of rat urine with ether followed by chromatography of the two layers showed that the compound of R_F 0·80 was more soluble than bemegride in the aqueous phase (the concentrations were estimated as the relative density of the spots on the autoradiographs). This partition was not changed when determined at *p*H 1 or 7, which indicates that the metabolic fraction is of a similar nature to the unchanged glutarimide. The partition between mouse urine and chloroform revealed that while the spots of R_F 0·88 and 0·79 were distributed between the two layers in a manner similar to that between rat urine and ether, the fraction of R_F 0·45 was confined to the aqueous layer. This shows that the slowest moving fraction is extremely soluble in water.

Failure to detect carbon dioxide labelled with carbon-14 in the expired air of mice receiving labelled bemegride suggests that there is no drastic degradation of the glutarimide molecule. The metabolic products of bemegride detected in the urine of the mouse and rat do not appear to be hydrolysis products of this glutarimide, for the R_F values of β-ethyl β-methyl-glutaramic acid and -glutaric acid are 0·97 and 0·99 respectively in *n*-butanol/acetic acid/water. Succinimide has been shown to be hydrolysed to succinic acid *in vivo*[2] but this metabolic pathway does not appear to be available for the glutarimides. This is supported by the finding that the imide ring of α-ethyl α-phenyl glutarimide remains intact *in vivo*[3]. It is also interesting to note that *Lactobacillus* species are unable to hydrolyse α-amino-glutarimide[4]. β-(2-hydroxyethyl) β-methyl glutarimide, isolated from the urine of a patient who received a large dose of bemegride[5], was found to have an R_F value (0·80–0·83) similar to that of the slower-moving fraction in rat urine, but results from studies in rats involving unlabelled bemegride suggest that these two fractions are not identical.

In the chromatographic location of the hydroxy derivative of bemegride use was made of the technique of Rydon and Smith[6]. This method has proved a simple and valuable means of locating glutarimides on paper chromatograms. The limit of sensitivity for detection is 20–30 μgm. of glutarimide/cm.[2]. By using a 2 per cent starch 1 per cent potassium iodide solution a good definition of the spots is obtained.

It is clear that bemegride, while excreted partly unchanged, is metabolized *in vivo* to produce more water-soluble compounds which probably possess an intact glutarimide ring. The metabolic pathways in the rat and mouse are similar.

Work is in progress to isolate and identify these metabolic products from the urine of mice and rats receiving unlabelled bemegride.

I wish to thank Dr. L. F. Wiggins of Aspro-Nicholas, Ltd., Slough, for supplying bemegride and other glutarimide compounds and also Dr. N. E. W. McCallum for the sample of β-(2-hydroxyethyl) β-methyl glutarimide. I acknowledge receipt of a Nicholas Research Grant of the Welsh National School of Medicine.

Histochemical Evidence of Aminopeptidase Activity in Rat Pineal Gland

ALTHOUGH various functions have been suggested for the pineal gland[1], very few positive findings have been made concerning this gland[2,3]. In this communication histochemical evidence is given of a strong enzyme activity in the rat's pineal gland capable of splitting L-leucyl-β-naphthylamide hydrochloride. Recent studies[4,5] indicate that this activity is actually due to a group of peptidases, including 'leucine aminopeptidase'.

The pineal glands of about 20 albino rats were studied. After removal from the animals the glands were embedded in brain and rapidly frozen. Fresh frozen cold microtome sections were cut at 30μ. The sections were fixed on coverslips and incubated according to the method of Nachlas *et al.*[6], using diazotized *ortho*-dianisidine or diazonium salt of 4-amino-3 : 2′-dimethyl azobenzene as the coupling agents.

The pineal body of the rat exhibited a strong aminopeptidase activity (Fig. 1). The contrast between the staining of the brain tissue and the pineal tissue was very pronounced ; when the sections were incubated for 30 min. the brain tissue showed practically no staining at all, whereas the pineal tissue was intensely stained. The enzyme activity of the pineal body was not, however, quite as strong as it was in the rat kidney. The aminopeptidase activity seemed to be evenly distributed throughout the gland ; the choroid plexus was infrequently cut together with the pineal body, and it was found to exhibit a moderate enzyme activity.

Pineal bodies of rats of different age groups ranging from 1 to 16 months showed an equal aminopeptidase activity. No sex differences either could be noticed.

Peptidase activity was also tested using *ortho*-acetyl-5-bromoindoxyl as a substrate at an acid medium and diethyl-*p*-nitrophenylphosphate (*E*600) as an esterase inhibitor[7]. This reaction was positive in the rat's pineal body as well, demonstrating cathepsin-*C*-like peptidase activity.

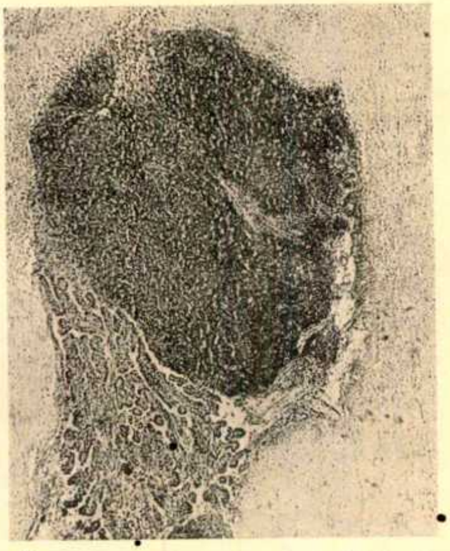

Fig. 1. Leucine aminopeptidase activity in pineal body of a normal adult rat. The choroid plexus beneath the gland shows enzyme activity as well, but the background staining of the brain tissue is due to decomposed diazonium salt (incubation time, 30 min.). (× *c.* 40)

So far as the proposed hormone production of the pineal gland is concerned, the present finding may be of interest. Pearse and Tremblay[8] have recently found an interesting correlation between the hormone production of the rat parathyroid gland and its content of histochemically demonstrable leucine aminopeptidase. The parathyroid hormone, on the other hand, is known to be a mixture of polypeptides. The existence of aminopeptidase activity can be taken to suggest secretion of some agent of a protein nature by the rat pineal gland.

Clearances of Endogenous α-Ketoglutaric and Pyruvic Acid in Man

THE clearances of endogenous α-ketoglutaric and pyruvic acids were investigated in six healthy persons and in ten patients with damaged kidney parenchyma. All persons were confined to bed during the whole experiment. α-Keto-acids were determined after their conversion to corresponding hydrazones which were separated by paper electrophoresis[1].

In all patients with kidney damage the creatinine clearance was lowered. The urine was collected in eight 2-hr. portions during a day and in two 4-hr. portions in the course of a night. (The mean values of clearances of α-ketoglutaric acid and of pyruvic acid was calculated from ten collection periods.)[2] The blood was deproteinized immediately after venipuncture and the clear supernatant was processed as usual.

The values of both the α-keto-acids in blood varied during a 24-hr. period. The variations averaged ± 15 per cent in the case of α-ketoglutaric acid and ± 20 per cent of values of pyruvic acid. 1·00–2·70 mgm. of α-ketoglutaric acid per 100 ml., and 0·90–1·70 mgm. of pyruvic acid per 100 ml. of urine were usually found. (The concentration was found to be dependent upon diuresis.) Women excreted more of these acids during 24 hr. than men ; this difference being accentuated in the case of α-ketoglutaric acid (Table 1).

The mean values of clearances of endogenous α-ketoglutaric and pyruvic acids were higher in women as compared with men (Table 1). In patients with kidney damage the values of both clearances were lowered ; the lowest one was found in nephritis of middle degree.

Highest values of clearances were observed between 1 p.m. and 5 p.m., and between 7 p.m. and 9 p.m.

The cause of different concentrations of both α-keto-acids in blood and urine is to be seen in kidneys. The kidney does not only eliminate the α-keto-acids, it participates in their metabolism, too[3]. The transaminations, oxidative deaminations, and oxidative

KG, α-Ketoglutaric acid ; *P*, pyruvic acid,

decarboxylations will be of principal importance here. It is possible to explain the relatively high concentration of α-ketoglutaric acid in urine (almost 10 times higher than that in blood) by either its lower reabsorption in renal tubules or by its higher elimination rate in the kidneys.

Respiratory Function of the Swim-bladder of *Notopterus* (Lacepede)

BRIDGE[1], working on the swim-bladder of *Notopterus borneensis* (Bleeker), and Srivastava[2], on that of *Notopterus chitala* (Buchanan-Hamilton), concentrated their attention only on the general plan of the organ.

A detailed account of the swim-bladder and its relation with the internal ear in the genus *Notopterus* has already been published by me[3]. During the course of study, the fish lived for an indefinite period in the laboratory even when the water in the aquarium became foul and contained less than 0·5 p.p.m. of dissolved oxygen for most of the time. The specimens of *N. chitala* and *N. notopterus* (Pallas) kept in the aquarium rose to the surface to gulp air at regular intervals. If they were prevented from rising they died in 4–6 hr. The duration of time between the two consecutive gulps of air varied generally from 2 to 8 min. under normal conditions. The frequency of surface visits increased after air was removed from the swim-bladder forcibly by pressing at its caudal cæcum (Fig. 1) or by drawing air out of the organ by means of a hypodermic syringe. Thus it may be presumed that a part of the air gulped by the fish enters its swim-bladder through its pneumatic duct at intervals and thus brings about a regular exchange of gases between the cavity of the organ and the exterior.

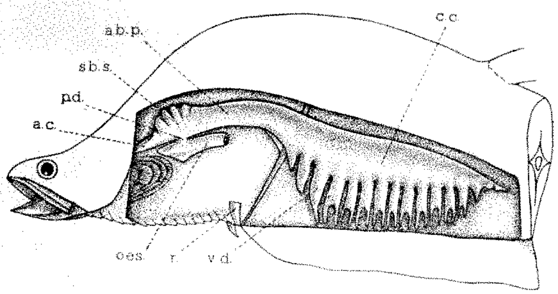

Fig. 1. Lateral view of swim-bladder of *Notopterus chitala*. *ab.p.*, Abdominal portion ; *a.c.*, auditory cæcum ; *c.c.*, caudal cæcum ; *oes.*, œsophagus ; *p.d.*, pneumatic duct ; *r.*, rectum ; *sb.s.*, subspherical sac ; *v.d.*, ventral diverticulum

Histological study of the swim-bladder wall shows that the tunica interna is abundantly supplied with blood capillaries. The blood is brought in close contact with the contained gases which diffuse through the thin layer of epithelial cells. The circulation of blood is modified in the organ to facilitate its function as an accessory respiratory organ on the plan observed by Carter and Beadle[4]. The blood supply is from the dorsal aorta and the oxygenated blood is drained back to the heart through the posterior cardinal vein.

Further evidence of aerial respiration came from the analyses of gases from the swim-bladder of the fish. The gases were drawn from the caudal cæcum of the swim-bladder by means of a hypodermic syringe and analysed by an apparatus made in the laboratory on the plan described by Fry[5]. Immediately after *N. chitala* had gulped air, the percentages of oxygen and carbon dioxide in the gases of its swim-bladder were found to be (mean) 16 and 0·5 respectively. But when the fish were prevented from gulping air for 10 min., the percentages of oxygen and carbon dioxide in the gases of its swim-bladder were found to be (mean) 6 and 4 respectively. The water contained 1 p.p.m. of dissolved oxygen and 20 p.p.m. of free carbon dioxide during the above observations.

The air-breathing habit of *Notopterus* has not been recorded so far. Behaviour of *Notopterus* regarding its aerial and aquatic respiration under various free carbon dioxide and dissolved oxygen contents in water is being studied. Work on the physiological aspects of its aerial respiration is in progress, and a detailed account will be published elsewhere.

I am grateful to Dr. M. Chandy, under whose guidance the above work was done. Thanks are due to Prof. M. L. Bhatia, for encouragement and facilities offered in the Department.

HÆMATOLOGY

Significance of Thrombin-*E* in the Prothrombin Activation Sequence

THROMBIN-*E*, or esterase thrombin, is an enzyme that uses fibrin monomer and fibrin as a substrate, but not fibrinogen[1,2]. Blood does not clot in the presence of thrombin-*E*, but on the contrary there is a tendency for lysis. It is derived from prothrombin, and arises before thrombin-*C*, which is the traditional enzyme considered in the blood coagulation literature[3]. In this report we emphasize the significance of thrombin-*E* in a prothrombin activation sequence. We describe some pharmacological effects of a purified thrombin-*E* preparation, chief of which is its fibrinolytic effect upon intravenous infusion in dogs. This *in vivo* fibrinolysis is far more powerful than its *in vitro* fibrinolytic effect. These facts are consistent with previous postulations[4,5] as follows: certain chemo-receptors excite themselves with thrombin and through a reflex arc call into play a neuro-humoral mechanism involving a physiological anti-coagulating system.

Two versions of the prothrombin activation sequence have been presented, but with no greater completeness than was comprehensible in view of the available information at the time[6,7]. With the knowledge that thrombin-*E* arises before thrombin-*C* an expanded sequence can be considered. First, there is prothrombin, which is recognized as a distinct single entity on the basis of isolation work[8,9]. It may activate according to the following sequence:

Prothrombin	becomes thrombin in two-stage analytical reagents
↓	
Prothrombin derivative I	does not become thrombin in two-stage analytical reagents
↓	
Prothrombin derivative II	becomes thrombin in two-stage analytical reagents
↓	
Thrombin-*E*	uses fibrin monomer and fibrin as substrate, but not fibrinogen
↓	
Thrombin-*C*	uses fibrinogen, fibrin monomer and fibrin as a substrate
↓	
Thrombin-*E*	uses fibrin monomer and fibrin as substrate, but not fibrinogen

Thrombin-*E* can be obtained from prothrombin in several ways. For example, by activating prothrombin in calcium solutions[2], or by letting thrombin-*C* preparations deteriorate[1]. But these ways are not practicable, for some thrombin-*C* usually remains and the yields are low. Later we hope to report on the derivation of a type of thrombin-*E* obtained by activation of acetylated prothrombin. It seems to be as convenient a way as by acetylation of thrombin-*C* [10], which was the method employed to get the material for our pharmacological studies.

Having achieved the preparation of homogeneous (ultracentrifuge) thrombin-*E* [10] we were ready to see, for the first time, some of its pharmacological effects. Approximately 15 mgm., dissolved in 100 ml. physiological saline solution, were infused in the femoral vein of a dog previously given 'Nembutal' anæsthesia. The infusion lasted over a period of an hour. There were no changes in blood pressure, respiratory and cardiac rate, or temperature. At completion of the infusion blood was drawn. Sometimes it clotted and then lysed. Sometimes the fibrinogen was depleted and there was no clotting. Of the several blood analyses done it was of interest to see a decrease in platelet and white cell count, and almost a two-fold increase in blood sugar and cholesterol concentration. By the end of 24 hr. all blood values were back to normal. The profound fibrinolysis is due to physiological mechanisms activated by thrombin-*E*. The equivalent concentrations or even a hundred times more of thrombin-*E* added to dog blood in test-tubes was never followed by visible lysis. On the other hand, plasma from dogs given infusions could be mixed with a standard fibrin clot and lysis was easily measured.

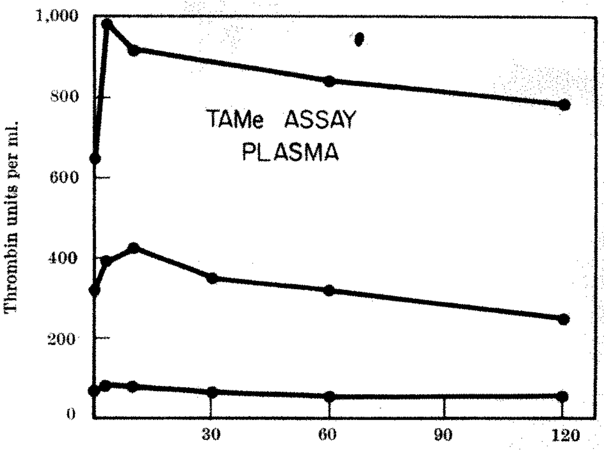

Fig. 1. Acetylated thrombin, in concentrations of 1,300, 650 and 130 units per ml., was mixed with an equal volume of defibrinated cow plasma. The activity at first increased and then declined to lower levels. The initial increase in activity was proportional to the thrombin-*E* concentration

To clarify the question of thrombin-*E* neutralization by antithrombin we made several analyses. In contrast to the rapid neutralization of the activity in thrombin-*C* [11] there seems to be an intensification of esterase activity during the first half hour after plasma is mixed with thrombin-*E* (Fig. 1). If the concentration of the latter is not too high it eventually is neutralized by antithrombin. Thus it is quite possible to have thrombin-*E* activity in the face of plasma antithrombin.

There are two facts that can be used to develop a perspective on the significance of thrombin-*E* in the prothrombin activation sequence. First, it arises before thrombin-*C*, and secondly, it activates fibrinolytic mechanisms in the intact mammal. The control of prothrombin activation is by a group of anticoagulants and procoagulants functioning in dynamic equilibrium[12]. With procoagulants gaining ascendency, thrombin-*E* can form and excite physiological mechanisms concerned with fibrinolysis. Even excess of thrombin-*E* is without danger so far as fibrinogen activation is concerned, and it is also not a catalyst for prothrombin activation[2]. However, if the prothrombin activation sequence goes farther we obtain thrombin-*C*. It can also excite fibrinolytic mechanisms[4,5], presumably through use of its thrombin-*E* component, but in 'excess' concentration it activates fibrinogen and clotting follows. Our results also account for the observed therapeutic effect obtained in cases of thrombosis where small amounts of crude thrombin-*E* preparations were infused[13]. The view that chemo-receptors react to the appearance of thrombin[4,5] focuses attention on events at an advanced stage of prothrombin activation. Already before that, thrombin-*E* can be effective, and it probably is constantly functioning to help maintain the fluidity of the blood, for it could be present in significant concentration at all times. For example, we made a few analyses and found five units of esterase activity in dog plasma and thirteen units in 2-hr.-old dog serum. This may not have been due to thrombin, but the same method for analysis was used as is routinely employed for the measurement of thrombin-*E* activity[1,2].

This investigation was supported by grant *H*-3424 from the National Heart Institute, National Institutes of Health, U.S. Public Health Service.

Erythrocyte Glucose-6-Phosphate Dehydrogenase-deficient Subjects: Enzyme-Level in Saliva

AN erythrocyte glucose-6-phosphate dehydrogenase deficiency has been described among Negroes, non-Ashkenazi Jews and Italians, mostly of Sardinian origin[1-3]. This enzymatic abnormality is known to be associated with an increased susceptibility to hæmolysis following ingestion of a number of drugs as well as of *fava* beans[4,5], and appears to be transmitted as a sex-linked incompletely dominant trait[6].

Recently, a low enzyme-level in the platelets, white blood-cells and liver-homogenates of affected subjects was demonstrated in our laboratory[7,8]. Marks *et al.* have also found low enzyme-levels in leucocytes of affected Caucasians in contrast to their previous reports on normal glucose-6-phosphate dehydrogenase activity in leucocytes of affected Negroes[9]. This apparent difference, in itself noteworthy, may be due to either (*a*) at least two or more independent genetic mutations, or (*b*) an effect of different genetic modifiers, which determine the degree of the enzyme defect in the population groups studied.

Since this genetic abnormality affects many primitive peoples, from whom we have had difficulties in obtaining blood, the search for other sampling methods to investigate this defect was undertaken. Saliva was found to be suitable for this purpose. Samples of it were obtained from twenty-six fasting subjects (controls), and from fourteen 'test cases', all males, deficient in glucose-6-phosphate dehydrogenase. The saliva samples were spun down at 1,000*g* for 15 min., 1 ml. of the supernatant being used for the assay. Glucose-6-phosphate dehydrogenase and 6-phosphogluconic dehydrogenase were assayed by previously described methods[8,10,11]. The enzymatic activity is expressed in units per mgm. of protein. The phosphogluconic dehydrogenase activity in enzyme-deficient individuals was not significantly different from that of normal subjects.

Table 1. GLUCOSE-6-PHOSPHATE DEHYDROGENASE (G-6-P.D.) ACTIVITY IN SALIVA OF NORMAL AND ENZYME-DEFICIENT SUBJECTS

Subjects	Number	G-6-P.D. level in units*	
		Range	Mean
Control	26	2–27	$8 \pm 6{\cdot}3$
Sensitive	14	0–1·22	$0{\cdot}54 \pm 0{\cdot}4$

$$^{*}\text{Unit} = \frac{(OD/\text{min.})}{(\text{mgm. protein})} \times 10^{3}$$

As can be seen in Table 1, the level of glucose-6-phosphate dehydrogenase in the saliva of 'test cases' is significantly lower than that in normal controls, ($P > 0{\cdot}001$) thus demonstrating that saliva, which is easily obtained, is suitable for the detection of enzyme-deficient subjects.

Preliminary investigation of the skin of normal and enzyme-deficient subjects has revealed that low enzyme-levels of the latter group are also demonstrable. These findings further support our observation that the genetic enzymatic defect in our population affects all tissues, not only the blood cells.

Inheritance of a New Group-Specific System demonstrated in Normal Human Sera by means of an Immuno-Electrophoretic Technique

IN a previous communication[1] a new group-specific system was demonstrated by means of a modified immuno-electrophoretic technique[1-3], and it has been shown that this system is not related to the hapto-globin groups[1,2]. Thus, by the content of either a fast-moving precipitating component (G.c.1), a slow-moving precipitating component (G.c.2) (Fig. 1), or a precipitating component which gives an immuno-precipitate with two peaks, human sera can be classified into three qualitatively different groups, which have been called groups 1, 3 and 2 respectively.

It has been shown that the precipitate with two peaks, or in less optimal circumstances, a plateau-like shape, can also be obtained by mixing sera belonging to groups 1 and 3 in equal amounts and subjecting them to immuno-electrophoresis. In all these instances (7 experiments with different sera) a precipitate is obtained which is indistinguishable from the precipitating component with two peaks found in certain normal sera, which are thereby characterized as belonging to serum group 2, and from these experiments presumably contain both the fast-moving and slow-moving precipitating components (Fig. 2)[1].

These group-specific components differ from the haptoglobins by their precipitates not taking the benzidine-stain after addition of hæmoglobin, they do not show any change in electrophoretic position after addition of hæmoglobin and are further found in all human sera hitherto investigated, including a few sera which were found to lack any haptoglobin demonstrable by starch-gel and agar-gel electrophoresis[3]. The group-specific components are found in the α_2-region occupying electrophoretic positions approximately corresponding to the haptoglobins 1–1 and 2–2, when sera are investigated without addition of hæmoglobin; but they are not correlated to the haptoglobin-groups determined in 30 sera by means of starch-gel electrophoresis.

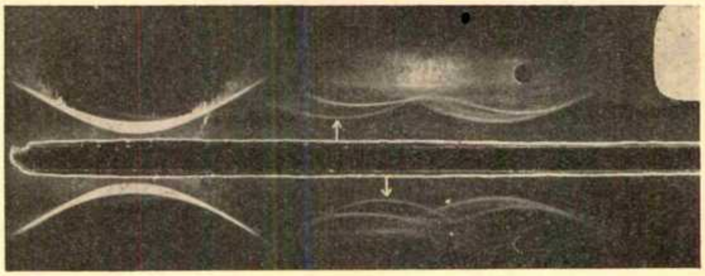

Fig. 1. Immuno-electrophoretic pattern of two normal sera characterized as belonging to group 1 (upper basin) and group 3 (lower basin). The group-specific components are indicated by arrows. To the far left, the position of albumin is shown

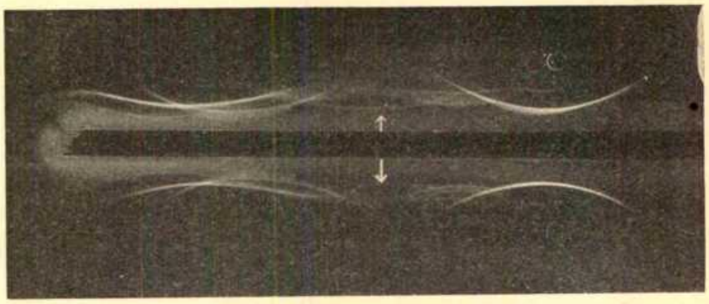

Fig. 2. Immuno-electrophoretic pattern obtained by mixing equal amounts of the same sera as in Fig. 1 (upper basin) as compared with a normal serum (lower basin) containing a precipitate with two peaks or at least a plateau-like form, the serum therefore characterized as belonging to group 2 or the heterozygote. A different immune serum is used from that in Fig. 1. This does not, however, affect the determination of the group-specific components

While it has not yet been excluded that these group-specific components might be identical with, for example, the post-albumins[4], the above-mentioned preliminary denotations will still be used.

In the present communication the results of a genetical study of mother–child material (kindly obtained from Prof. Birger Broman, State Institute for Blood Group Serology, Stockholm) and family material (kindly obtained from Prof. Rune Grubb, Bacteriological Department, Lund) will be given.

Family data are summarized in Table 1. They are in agreement with the interpretation that the character is monogenetically inherited and that types 1 and 3 represent the two homozygous classes and type 2 is the heterozygote.

Table 1

Parental phenotypes		No. of families	No. of children belonging to type			Total
Father	Mother		1	2	3	
1	1	6	30	0	0	30
1	2	2	4	2	0	6
2	1	4	4	7	0	11
2	2	3	2	3	1	6
1	3	1	0	2	0	2
3	1	1	0	3	0	3

Table 2

	Number of individuals belonging to type			Total
	1	2	3	
Observed	161	108	23	292
Expected	158·3	113·4	20·3	292

$\chi^2 = 0\cdot662$, 1 degree of freedom. $P = 0\cdot3$–$0\cdot5$.

A randomly sampled specimen of mother–child material confirmed this hypothesis, in that among 76 mothers of type 1 no one had a child of type 3, and among 14 mothers of type 3 no one had a child of type 1. Gene frequencies were estimated from these data, tabulated in Table 2, using the scoring method devised by Cotterman[5] for material composed of related individuals. The frequency of the allele responsible for the fast-moving component was found to be 0·74 and the frequency of the other allele 0·26. A χ^2-test for the agreement with the postulated manner of inheritance and for genetic equilibrium was performed (Table 2). The deviations from the expected frequencies are very small and not statistically significant.

PLANT PHYSIOLOGY

Effect of Coumarin on the Growth of *Rhodotorula rosea* Cultures

Coumarin ($C_6H_4OCOH{=}CH$) and closely related compounds are strong regulators of the germination and growth of seedlings of different species of plants[1]; the stimulatory[2] or the inhibitory[3,4] effect depends on the concentration of coumarin and on the species of plant tested. Unfortunately, there is almost no information concerning the effect of coumarin on the growth of micro-organisms[5] and we have, therefore, carried out tests with *Rhodotorula rosea*.

Into 100 ml. Erlenmeyer flasks were poured 24·5 ml. synthetic nutrient medium[6] (twice condensed), 24·5 ml. special solution of coumarin, or distilled water in the case of control, and sterilized in an autoclave. After cooling, 1 ml. suspension of *Rh. rosea* (48-hr. culture grown on sweet beer, by dilution 1 : 10,000) was added to each flask, which was then placed in a thermostat at a temperature of 27° C.

The growth of micro-organisms was measured by microscopic observations of preparations stained with methylene blue solution according to Fink and Kühles[7] in Thoma's counting chamber. Besides the whole number of cells, dead and budding cells were also counted.

The results are presented in Tables 1 and 2.

Table 1. Effect of Coumarin Concentrations on Rate of Growth of *Rhodotorula rosea* after Various Times

Concentration of coumarin (p.p.m.)	Percentage of growth after (hr.) 48	72	96
0 (control)	100	100	100
1·0	81·2	72·4	64·0
10·0	152·9	112·3	78·4
100·0	77·1	53·8	36·1
1,000·0	6·4	4·6	2·0

Table 2. Effect of Coumarin on the Degree of Budding and Dead Cells

Concentration of coumarin (p.p.m.)	Percentage budding after (hr.)			Percentage dead after (hr.)		
	48	72	96	48	72	96
0 (control)	72·6	67·8	77·1	8·3	6·2	4·7
1·0	68·0	69·9	73·9	8·6	9·4	6·4
10·0	78·7	81·0	78·2	5·4	5·3	6·5
100·0	55·6	57·9	68·8	9·5	20·3	14·7
1,000·0	14·4	29·4	0	42·8	58·9	96·1

Note: all numbers are the average of 3–4 repetitions.

The results in Table 1 show that coumarin can stimulate or inhibit the growth of culture *Rh. rosea*, depending on time and concentration. At a concentration of 1,000 p.p.m. it almost totally inhibits development of the yeast: in a 48-hr. culture there are only 6 per cent of cells compared with the control; in this case 43 per cent of cells are dead. In a 96-hr. culture there are only 2 per cent, and in this case almost all cells are dead. The fact must be recognized that the cells alive in a culture such as this change very much morphologically (unpublished work).

Interesting results are obtained in cultures after adding coumarin at a concentration of 10 p.p.m. After 48 hr. in such a culture there is an increase of the whole amount of cells to the extent of 50 per cent (152–100 per cent of control); in cultures lasting 72 hr. stimulation decreases to about 12 per cent. In cultures lasting 96 hr., however, instead of stimulation, an inhibition of about 20 per cent of growth is observed. It is important that the decrease of stimulation with ensuing inhibition is proportional to the time of growing culture on nutrient medium with a supply of coumarin.

Parallel to the increase of the whole amount of cells in cultures treated with coumarin at a concentration of 10 p.p.m. there is an increase in the number of budding cells, but there is a decrease in the number of dead cells (expressed as a percentage of the whole number of cells in the given series taken as 100 per cent); by passing from stimulation to inhibition, at the same time, the increase of the amount of dead percentage of cells is observed.

An important problem is that coumarin in a concentration of 1 p.p.m. shows inhibitory action.

On the basis of the investigations described above it may be suggested that coumarin has a decisive influence on the living process of the yeasts (we obtained similar results on *Saccharomyces cerevisiae*), and it is very probable that it influences the development of other strains of micro-organisms.

We thank Prof. W. Moycho for his critical remarks made while working on this problem.

A Reversible Inhibition of Photosynthesis in Synchronized Cultures of Algae

Steady-state algal suspensions have been a favourite subject in studies of inhibitory effects of light on photosynthesis[1–5]. Light intensities several times higher than the intensity of full sunlight were often employed. The unfavourable effects of strong light were seen in the decreased photosynthetic rates[1–4] and/or in the destruction of the photosynthetic pigments[5]. A recovery process has been observed after transferring the organism into dark or to lower light intensities[3,4,5]. An emphasis on the dependence of the photo-inhibition on a very strong light has obscured the much wider nature of the phenomenon. The general employment of steady-state suspensions precluded an insight into the complexity of the situation on the cellular level.

A steady-state microbial population consists of cells of different developmental stages. Any characteristic obtained for a steady-state suspension is a statistical average from the characteristics of the individual cells and, like any average, it may or may not be intrinsic to any portion, or, strictly speaking, even to a single cell, of a given population. It has been shown that in the course of the life-cycle *Chlorella* cells pass through stages which differ in the levels of metabolic and growth activity[6–9], in the contents of cell constituents[10,11], and in the sensitivity to environmental factors[12].

The effect of light on photosynthesis in cells of different developmental stages also proved to be

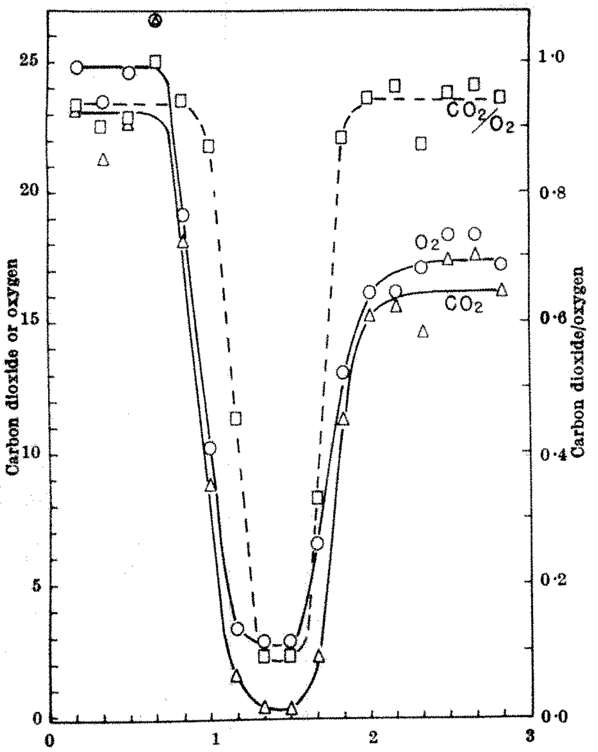

Fig. 1. Time course of the gas exchange during a photosynthetic experiment in 3-hr.-old cells of *Chlorella* 7–11–05. Carbon dioxide consumption and oxygen evolution in mm.^{3} of gas per mm.^{3} of cells per 10-min. intervals. Assimilatory quotients (carbon dioxide/oxygen) for the corresponding intervals. Note recovery of rates for all measurements

different[13]. Cells of a certain intermediate age are characterized by a higher position of the light-saturating point and by higher rates of photosynthesis at light saturation. In the course of a photosynthetic experiment these cells show a peculiar phenomenon. The rate of the gas exchange first declines; then, after reaching a low point, it increases and may eventually reach or surpass the level of the initial rate at the start of the experiment.

The results depicted in Fig. 1 were obtained with a synchronized suspension of the high-temperature strain, *Chlorella* 7–11–05[7,8]. Cells 3 hr. old were used. Studies were done with the two-vessel technique in 0·02 *M* potassium dihydrogen phosphate-suspending fluid at *p*H 4·5. Temperature during both the culturing period and photosynthesis measurements was maintained at 39° C. Illumination during photosynthesis studies was provided by incandescent lamps with the intensity at the level of the reaction vessels near 2,000 foot candles. This intensity is slightly higher than the saturating light intensity for the steady-state suspensions of this strain (near 1,600 foot candles)[14].

As seen in Fig. 1 both the oxygen evolution and carbon dioxide consumption undergo sharp declines with time. Carbon dioxide consumption is affected more than oxygen evolution and, consequently, the assimilatory quotient (carbon dioxide/oxygen) drops to a very low level. In some experiments the carbon dioxide consumption was even observed to turn into carbon dioxide evolution and the oxygen evolution into oxygen consumption.

After reaching a low level the rates of gas exchange start to rise. Eventually they may reach the initial level or even surpass it. The rate of the recovery of carbon dioxide consumption is higher than that of oxygen evolution and, as a result, the assimilatory quotient gradually rises to the initial level at the start of the experiment.

For comparison, the time course of the events in a steady-state suspension of the same strain and under similar conditions is depicted in Fig. 2. The rate of oxygen evolution declines with the time in accordance with earlier observations by Emerson[1]. Carbon dioxide consumption also shows a gradual though slightly greater decrease with time. As the result, assimilatory quotient slightly decreases during the course of the experiment. Changes in the rates of the gas exchange in the steady-state suspension are not nearly so dramatic as in synchronized 3-hr. cells and recovery of the rate does not occur.

A clue to the discrepancy in the time course of photosynthetic gas exchange in synchronized 3-hr.-old cells (Fig. 1) and in a steady-state suspension (Fig. 2) is provided by an understanding of the diversity of cellular characteristics among members of a steady-state microbial population. It will be shown in following publications that algal cells of later developmental stages have a very low if any capacity for a recovery of photosynthetic rate in the course of the experiment. The time course of the photosynthetic gas exchange in older cells would be described by a constantly decreasing rate with the slope of the curve much steeper than that depicted in Fig. 2 for the steady-state suspension. At any given time during the measurement of photosynthesis the rate of the gas exchange for the steady-state suspension is an average of the rates of cells in all possible developmental stages. The preponderance

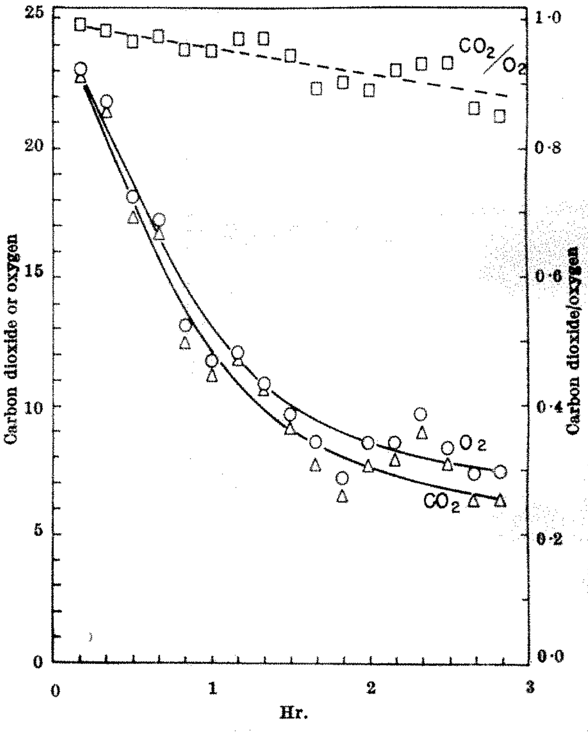

Fig. 2. Time course of the gas exchange during a photosynthetic experiment in a steady-state suspension of *Chlorella* 7–11–05. Carbon dioxide consumption and oxygen evolution in mm.^{3} of gas per mm.^{3} of cells per 10-min. intervals. Assimilatory quotients (carbon dioxide/oxygen) for the corresponding intervals. Note absence of recovery of rates

in such a suspension of older cells in later developmental stages results in a curve described in Fig. 2.

A basic observation from these studies is that the decrease in the rate of the photosynthetic gas exchange occurs at illuminance assumed to be most favourable for photosynthesis—just above light-saturating intensity. This decrease has nothing to do with the "lack of essential nutrient salts"[1] and it is not "the result of injury by the phosphate solution"[1] since the inhibition can be followed by a recovery of the rate without any apparent change in experimental conditions. The recovery of the rates is not connected with growth phenomena in the common sense of the word. Under conditions employed in these investigations, both these processes—the inhibition of photosynthesis and the increase in the rate as the result of building up some participants of the photosynthetic process—go simultaneously, the actual rate of the gas exchange being a consequence of the inter-play of these participating processes.

The magnitude of these two processes, and, therefore, the outcome of the competition between them, is greatly affected by the time factor in the course of the experiment and by the developmental stage of the cells. A resolution of the intricate intimacy of photosynthesis and development may prove advantageous in studies of both these processes.

The work has been supported by funds from the Office of Naval Research.

PATHOLOGY

Effect of Salicylate on the Activity of Plasma Enzymes in the Rabbit

ELEVATIONS of glutamic-oxaloacetic and glutamic-pyruvic transaminases have been reported to occur in sera from more than 50 per cent of children with rheumatic fever treated with either aspirin or sodium salicylate[1]. The injection of sodium salicylate in the rat caused an increased activity of xanthine dehydrogenase in the blood but a decreased activity of the enzyme in the liver, and it was suggested that the salicylate caused liver and other tissue damage leading to an increased rate of release of enzyme protein into the circulation[2]. We have therefore studied the effects of prolonged oral administration of salicylate on the activities of five plasma enzymes and on tissue histology in the rabbit.

Eight adult rabbits were given salicylate, in three divided doses each day, as either 5-grain soluble aspirin tablets B.P. or as 1 gm. per ml. aqueous solution of sodium salicylate. The aspirin tablets or the sodium salicylate solution were either placed or delivered from a syringe at the back of the animal's tongue and were readily swallowed when the mouth was then held shut. After an initial control period of two weeks, each rabbit received 0·75, 1·0 or 1·5 mgm. of the aspirin or sodium salicylate per gm. of body-weight each day for successive two-week periods. Blood specimens were collected from ear veins into heparinized containers at twice-weekly intervals and the separated plasma analysed for salicylates[3], glutamic-oxaloacetic and glutamic-pyruvic transaminases[4], *iso*citric dehydrogenase[5], lactic dehydrogenase[6] and aldolase[7]. The rabbits were killed by intravenous nembutal and portions of the liver and other tissues were removed and fixed in formol-saline for histological examination. Normal values for the activities of the five plasma enzymes in the rabbit were established by analysing random blood samples from 25 adult animals (Table 1).

Table 1. PLASMA ENZYME ACTIVITIES IN 25 CONTROL RABBITS
Results given as means and standard deviations

Enzyme	Units per ml. of plasma	Incubation temperature (° C.)
Glutamic oxaloacetic transaminase (*GOT*)	15·3 ± 4·6	37
Glutamic-pyruvic transaminase (*GPT*)	22·0 ± 8·5	37
Lactic dehydrogenase (*LD*)	5·2 ± 1·9	25
*iso*Citric dehydrogenase (*ICD*)	270 ± 90	25
Aldolase (*Ald.*)	10·8 ± 4·9	37

Increases in the activity of plasma enzymes were observed in six rabbits during the experiment, and typical results from two animals showing a marked and progressive rise in all the enzyme activities are given in Table 2.

Table 2. ACTIVITIES OF PLASMA ENZYMES IN TWO RABBITS

Day of experiment	Plasma salicylate (mgm./ 100 ml.)	Activity of plasma enzymes (units/ml.) *GOT*	*GPT*	*LD*	*ICD*	*Ald.*
30	52	9	12	15	280	8
32	64	11	8	34	660	6
37	78	58	18	60	820	73
40	75	203	25	132	3,200	150
19	38	5	3	4	160	9
24	52	7	4	12	170	5
27	31	26	40	12	2,600	34
29	52	780	140	32	4,000	125

It was necessary both to achieve and maintain plasma salicylate concentrations higher than 30 mgm. per 100 ml. in the susceptible rabbits to produce increased activity of plasma enzymes, and the time intervals between the initiation of salicylate administration and the first appearance of an enzyme abnormality ranged from 13 to 33 days. Histological examination revealed unequivocal signs of liver damage (cloudy swelling and fatty infiltration) in two of the six rabbits showing increased activity of plasma enzymes. The other tissues of these two rabbits and the tissues of the remaining animals were histologically normal.

The results show that the prolonged oral administration of salicylate caused increased activity of plasma enzymes in 6 out of 8 rabbits, but this was associated with definite signs of liver damage in only 2 of the animals. It is possible that these two rabbits represent an extreme case and that the liver and other tissue damage in the remaining animals was not gross enough to be detected by conventional histological methods. Zierler[8] has observed an increased flow of aldolase across rat muscle under conditions, such as anoxia, which alter muscle metabolism and membrane permeability. Concentrations of salicylate greater than 30 mgm. per 100 ml. uncouple oxidative phosphorylation reactions in mitochondrial suspensions and in the isolated rat diaphragm[9] and thus inhibit the synthesis of adenosine triphosphate. The selective permeability of cellular membranes depends on a normal rate of production of adenosine triphosphate. The uncoupling action of salicylate may therefore affect the permeability of many tissues, leading to an increased flow of enzyme proteins into the blood without producing structural damage to the tissues of such a degree that it would necessarily be seen during the histological examination of fixed tissues.

Intracellular Potassium in Dietary Liver Necrosis

THIN slices of liver from rats fed a normal diet (M.R.C. 41*B* cubes) lose potassium when placed in cold saline solution and re-accumulate potassium against a concentration gradient when placed in warm oxygenated Ringer solution. Mudge[1] has shown a similar sequence of events to take place in rabbit kidney slices, and Aebi[2] has shown that rat liver slices can maintain a concentration gradient between internal potassium and the incubation medium if the incubation conditions are favourable.

Dietary liver necrosis is a condition which overtakes young rats fed the diet of Himsworth[3]. The diet consists mainly of yeast and starch and is severely deficient in α-tocopherol. Liver necrosis occurs suddenly about 17 days after weaning the rats to the yeast diet[4]. Apart from mild fatty infiltration the livers are histologically normal until necrosis occurs. Feeding α-tocopherol prevents necrosis. In the present investigation liver slices from rats fed the necrogenic diet of Himsworth were found to be unable to re-accumulate potassium when placed in warm oxygenated Ringer solution after losing potassium in a cold saline solution.

Table 1. POTASSIUM CONTENT OF LIVER SLICES AFTER INCUBATION IN THE COLD FOR 35 MIN. AND THEN IN WARM OXYGENATED RINGER FOR 60–80 MIN.

Diet	No. of animals	Potassium content (m.equiv./kgm. dry weight)
Stock or yeast + α-tocopherol	5	300 ± 30
Yeast diet 3–6 days	4	116 ± 13
Yeast diet 7 or more days	8	70 ± 18

Histologically normal livers from animals fed the necrogenic diet are referred to as prenecrotic livers, and the livers of animals which had been fed the diet for more than 9 days are considered as being in the late prenecrotic stage.

Pieces of liver and liver slices were dried to find water content, and then extracted with 0·15 *N* nitric acid. Sodium and potassium were measured in this extract with a flame photometer[5].

The livers of rats fed the necrogenic diet have a potassium content similar to that of livers of rats fed stock diet, or fed the necrogenic diet plus α-tocopherol. In frankly necrotic livers the potassium content is low.

Slices from prenecrotic livers and normal livers lose similar amounts of potassium when placed in a cold saline solution (sodium chloride, 150 m.equiv./l., potassium chloride, 5 m.equiv./l. at 0·5° C.). But when slices from prenecrotic livers are then placed in warm oxygenated Ringer solution they differ from slices of normal livers in showing a progressive failure to re-accumulate potassium (Fig. 1, Table 1). (Ringer phosphate, ref. 6, with 1·2 m*M* calcium and 6·6 m*M* potassium made up with water first distilled and then deionized in a 'Permutit' mixed-bed ion-exchange resin column is used as incubation medium.)

This inability is noticeable in slices from rats fed the diet for three days and becomes more severe as the time of feeding the diet increases.

The difference between slices from prenecrotic and from control livers can be detected in the first 20 min. of incubation. Slices from late prenecrotic livers

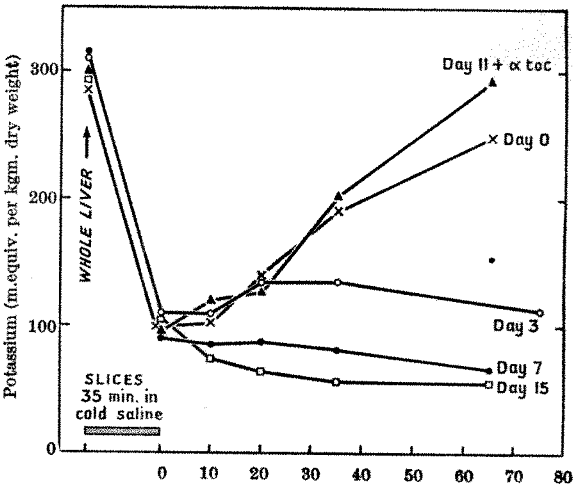

Fig. 1. Potassium accumulation in liver slices. Slices from rats fed necrogenic diet for increasing number of days. Day 11 + α-toc.: rat given 3 mgm. α-tocopherol 24 hr. before being killed. All slices kept in saline at 0° C. for 35 min. and then incubated in warm oxygenated Ringer solution

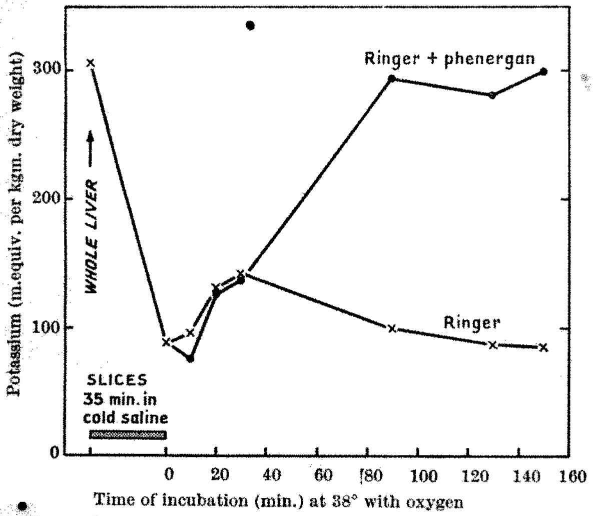

Fig. 2. Potassium accumulation in liver slices. Rat fed necrogenic diet for 5 days. Slices kept in saline at 0° C. for 35 min. and then incubated in warm oxygenated Ringer solution, with and without addition of 10^{-4} *M* 'Phenergan'

show a decline in oxygen uptake after the first 30 min. of incubation[4,7].

If a rat in the late prenecrotic stage is given α-tocopherol, liver slices taken 24 hr. later can accumulate potassium, like liver slices from rats fed stock diet, and oxygen uptake of slices does not decline. If slices from prenecrotic livers are incubated in Ringer solution containing 10^{-4} *M* 'Phenergan' (10-(2-dimethylamino*iso*propyl)phenothiazine hydrochloride), potassium accumulation is restored nearly to normal and oxygen uptake does not decline[4] (Fig. 2).

Sodium and water content of all these slices alter together and in a reciprocal manner to potassium content.

Homogenates of prenecrotic livers carry out oxidative phosphorylation with normal phosphorus/oxygen ratios.

Since the failure to re-accumulate potassium occurs in the early days of feeding the necrogenic diet, and since this failure occurs in the first 30 min. of incubation, the failure of oxygen uptake which occurs later may well be secondary to changes of electrolyte and water in the slices.

It is suggested, therefore, that these slices from prenecrotic livers probably exhibit the basic cell defect of dietary liver necrosis, namely, an inability to re-accumulate potassium once the internal cell structure has been disturbed by trauma, such as cold. The physiological source of trauma which causes *in vivo* necrosis is being sought.

This work was undertaken during the tenure of a Colonial Medical Research Studentship.

Pathogenesis of Thrombosis

THE pathogenesis of thrombosis in man is still to a considerable extent a mystery despite the considerable advances in knowledge of the subject in recent years.

In 1924 Aschoff postulated the following mechanisms as being important in intravascular clotting: (1) Changes in the coagulability of the blood, (2) changes in the formed elements, (3) changes in the blood flow, (4) changes in the blood vessels.

To these may be added several other factors more or less represented in Aschoff's scheme: the ingestion of fats[1] or alternatively essential fatty acid deficiency[2]; ageing; stress; lack of exercise; female sex hormone; tobacco smoking; operations and pregnancy. The exact importance of several of these factors is still in a good deal of doubt, however.

Changes in the coagulability of the blood have been measured by clotting time tests by several methods, by many authors, in an endeavour to determine the presence of accelerated clotting in thrombosis, with variable results. Significant shortening of the heparin plasma clotting time within 48 hr. of the onset of vascular occlusion was reported by Poller[3]. The precise relationship of such accelerated clotting to vascular thrombus formation is not established and it has been suggested that it may be, in part at least, secondary, due to the release into the circulation of coagulation products activated during clotting[4].

Studies of more specific aspects of the coagulation pattern have been performed by numerous investigators. Increases of prothrombin activity[5], factor VII [6], fibrinogen[7], antithrombin[8], thromboplastin generation[6,7] and reduced fibrinolytic activity[9] have been reported in recent thrombosis.

Changes in the formed elements have included the measurement of platelet 'stickiness', which has been found to be increased by several authors.

Changes in the blood flow have not been extensively studied owing to the difficulty of simulating events *in vivo*.

The principal anatomical vascular change predisposing to thrombosis is atherosclerosis. Duguid[10] believes organization of intra-arterial clots and fibrin deposits to be a major cause of this.

The following simple experiment may be related to the third and fourth mechanisms postulated by Aschoff[11]: 20 ml. venous blood was collected into a siliconed syringe with the minimum of hæmostasis. It was then transferred to two wax-stoppered siliconed tubes, 10 ml. being placed in each. Instead of being allowed to clot in the normal way in the rack of a water-bath the tubes of blood were transferred to an electrical blood-mixer which rotates slowly at 30 revolutions per min., imparting a slow to-and-fro motion to the blood which may simulate the pulsatile blood flow in an elastic artery like the aorta.

Under these conditions, instead of a solid clot forming, coagulation took the form of a fine deposit of fibrin on the walls of the tubes. One of the tubes was removed from the mixer after 2 hr. and transferred to a rack in a water-bath. In this a visible solid clot formed. The other tube was left in the mixer for 12 hr., but in this instance a solid clot never formed on removal to a water-bath.

If this experiment simulates at all the events *in vivo* the following conclusions may be drawn: (1) blood clotting in a major vessel with good circulatory blood flow takes the form of fibrin deposition on the walls, which supports Duguid's 'thrombogenic' theory of atherosclerosis; (2) that a firm solid clot only forms in an artery when the local pulsatile blood flow is arrested.

The experiment is probably not related to events in venous thrombosis as the blood flow is sluggish, non-pulsatile, and atherosclerosis absent.

ANATOMY

Marchi-Positive Bodies in Human Globus Pallidus

THE Marchi method has been used extensively in this laboratory in the course of studies on degenerating nerve fibres in the central nervous system made during the past twelve years. The purpose of this communication is to report the invariable occurrence of black, Marchi-positive bodies in the globus pallidus in brains examined by this method. This is an incidental finding, unconnected with the nerve fibre degeneration under study. No previous report of it has been found in the literature.

More than 250 brains have been examined by this method. These brains came from patients dying from a wide variety of neurological and non-neurological conditions. In every brain examined there is black staining in the pallida, the amount of staining varying from brain to brain, but being approximately the same on the two sides in each brain. This black staining is in the form of rounded 'bodies' of varying size arranged in groups, frequently consisting of one or two larger 'bodies' surrounded by a number of small 'bodies'; their diameter varies from 1μ to 60μ (Figs. 1 and 2). The 'bodies' are not intracellular and are not enclosed within the sheaths of nerve fibres. Their appearance is the same in horizontal, oblique and coronal planes of section.

Sections from blocks next to those prepared by the Marchi method have been stained by the usual variety of neuro-histological methods to show changes in neurones, nerve fibres and glia. A few pink 'droplets' have occasionally been seen in sharlach *R* preparations which might be the equivalent of some of the Marchi-stained 'bodies', but otherwise no such 'bodies' have been seen in sections stained by any other method.

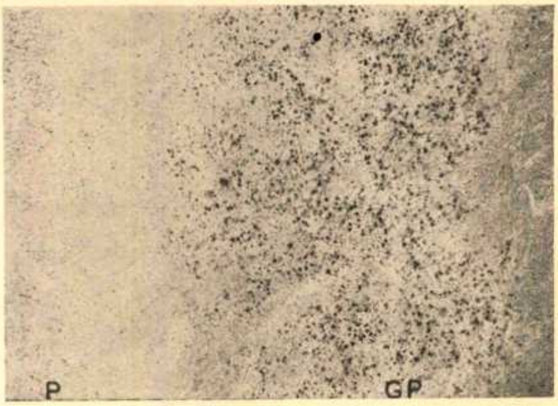

Fig. 1. Marchi preparation of putamen (*P*) and globus pallidus (*GP*) from normal brain, showing black, Marchi-positive 'bodies' in globus pallidus (× *c*. 13·5)

The purpose of the Marchi method is to demonstrate the presence of degenerating myelin. The essential mechanism in the method is the reduction of osmium tetroxide to osmium dioxide, which is black. Both normal and degenerating myelin cause this reduction; but it is inhibited in normal myelin by the addition of potassium dichromate or chlorate to the osmium tetroxide. Thus, in principle, only degenerating myelin stains black. In practice, artefacts of various kind may occur with this method. It must be stressed that the 'bodies' now described are completely unlike any of the artefacts ever seen, and that they are completely unlike any form of black staining in the central nervous system known to be associated with the degeneration of myelinated nerve fibres.

These bodies have a constancy of 'structure' which makes recognition of the globus pallidus easy even in tiny pieces of basal ganglia. No such 'bodies' have been found in the putamen, but very occasionally a very small number are present in the adjoining part of the internal capsule and/or in the more cranial part of the substantia nigra.

Various factors have been considered with reference to the occurrence and number of the 'bodies'. More than 250 brains have been examined by the Marchi method. Neoplastic disease, most frequently of the pelvic organs, was the most common cause of death, but brains from patients who died because of cardiac disease, of various forms of accident with and without head injury, pneumonia, tuberculosis, poliomyelitis, polyneuritis and different degenerative diseases of the nervous system were all examined. As mentioned already, the 'bodies' in the globus pallidus varied in number from brain to brain, but there were some present in all brains. No correlation could be established between the cause of death and the abundance

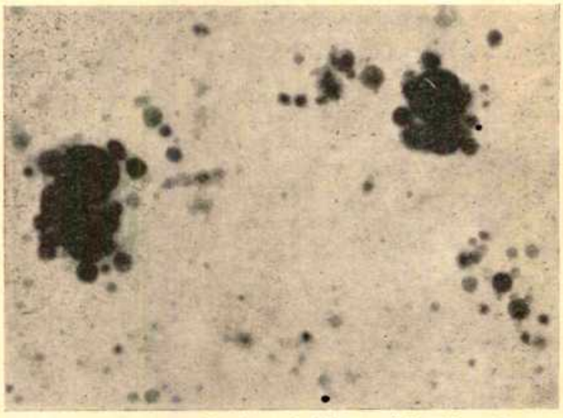

Fig. 2. Higher magnification of globus pallidus from Fig. 1, showing grouping of black 'bodies' (× *c*. 600)

of the 'bodies'. Similarly, no correlation could be established between the age of the patients, which varied from 20 to more than 70 years, and the number of the 'bodies'.

Although unlikely, the question might be raised whether the post-mortem treatment of the brains might have something to do with the occurrence and number of the 'bodies'. The interval between death and post-mortem varied from 2 hr. to 3 days. As the brains came not only from this hospital but from many other hospitals throughout the country, the possible effect of variations in the techniques of examination and of fixation can be excluded. No correlation could be established between the interval between death and fixation and the number of the 'bodies'.

The brains from a few species other than man have been examined by the Marchi method. These came from rhesus monkeys, cats, horses, sheep, guinea pigs, rats and mice. In none of these brains were any of these 'bodies' seen. However, the number of animals examined was too small for any definite conclusion to be drawn about the absence of these 'bodies' in mammals other than man.

At present no conclusion as to the nature of these 'bodies' is possible; but it is tentatively suggested that they may indicate some biochemical feature characteristic of the globus pallidus which has not yet been identified. Much interest is now focused on the basal ganglia. It is possible that with increasing knowledge of this region the significance of the findings reported here will become recognized.

BIOLOGY

Dorsal Fontanelles in Selachian Neurocrania

Since the classical work of Gegenbaur[1] and Parker[2] the anterior opening lying on the dorsal surface of the selachian neurocrania is generally termed 'anterior fontanelle' in spite of the fact that it is different in its morphological significance and relations in different selachians. In some forms, posterior to this fontanelle, a small opening, the epiphysial foramen, is found; and in others another fontanelle, which is generally termed the 'supracranial fontanelle', appears. The study of several species of several families of Selachii showed that it is of great importance to name such fontanelles according to their morphological relation with the cranial cavity.

In *Squalus blainvillii* the fontanelle lies beyond the morphological anterior wall of the cranial cavity and represents the dorsal opening of the cavum præcerebrale found inside the spout-shaped rostral cartilage, and is accordingly named the precerebral fontanelle. Posterior to this fontanelle a small epiphysial foramen occurs. In *Squatina oculata* the fontanelle is completely supracranial, as the morphological anterior wall of the cranial cavity extends to its anterior margin. Behind it is a small epiphysial foramen. In *Triaenodon obesus* the brain extends anteriorly beyond the posterior edge of the fontanelle and thus it can be differentiated into two morphologically different parts: the anterior supracranial fontanelle lying above the cranial cavity, and the precerebral fontanelle representing the dorsal opening of the cavum præcerebrale enclosed between the three rostral cartilages. In *Torpedo sinus* the fontanelle is morphologically similar to that of *Triaenodon*, and posterior to it lies the epiphysial foramen. In *Raja batis* there are two large fontanelles separated by a narrow cartilaginous bridge. The anterior is differentiated into a precerebral fontanelle leading to the cavum præcerebrale inside the rostral cartilage, and an anterior supracranial fontanelle. The posterior is completely supracranial and is, here, termed the posterior supracranial fontanelle to differentiate it from the anterior one. In *Taeniura forskali* is found only one large fontanelle, which is completely supracranial, and termed the supracranial fontanelle.

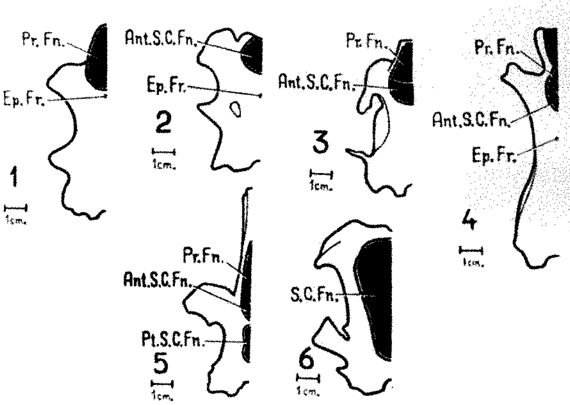

Fig. 1. Dorsal view of the neurocranium of: 1, *Squalus blainvillii*; 2, *Squatina oculata*; 3, *Triaenodon obesus*; 4, *Torpedo sinus*; 5, *Raja batis*; 6, *Taeniura forskali*. *Ant.S.C.Fn.*, Anterior supracranial fontanelle; *Ep.Fr.*, epiphysial foramen; *Pr.Fn.*, precerebral fontanelle; *Pt.S.C.Fn.*, posterior supracranial fontanelle; *S.C.Fn.*, supracranial fontanelle

Such comparative study of the dorsal fontanelles in different selachian neurocrania shows that when rostral cartilages are not present the fontanelles are morphologically supracranial as in the case of *Squatina* and *Taeniura*. In cases where rostral cartilages are present a precerebral fontanelle is represented, and it may be the only fontanelle present as in *Squalus*, or it may be confluent with a supracranial fontanelle as in *Triaenodon*, *Torpedo* and *Raja*. This view can be substantiated by the embryological work of El-Toubi[3] and Hamdy[4], who show that the single, spout-shaped rostral cartilage develops from three strips of cartilage having the same relations as the triradiate rostral cartilages. Thus it is easy to homologize the whole fontanelle in *Squalus* with only the precerebral fontanelle in *Triaenodon*, *Torpedo* and *Raja*; the anterior supracranial fontanelle in *Triaenodon*, *Torpedo* and *Raja* with that of *Squatina*; and the whole fontanelle in *Taeniura* with both the anterior and posterior supracranial fontanelles in *Raja*, being confluent with each other in consequence of the absence of the cartilaginous bridge separating them in the latter fish.

Spore Release in *Peronospora tabacina* Adam.

DOWNY mildew or blue mould of tobacco caused by *Peronospora tabacina* Adam. is destructive in the American and Australian regions and has now been reported for the first time in Europe[1]. It survives in association with over-wintering or over-summering host plants of which infected *N. tabacum* is of major importance[2,3]. Such plants produce conidia that are airborne and can establish infection in distant areas[2].

De Bary suggested that dissemination of conidia of *Phytophthora infestans* (Mont.) de B. was brought about by changes in humidity causing violent movement of conidiophores and conidia were "thrown off in every direction"[4]. Ingold[5] did not agree with de Bary's conclusion ; but Pinckard[6], working with *Peronospora tabacina*, supported it and also reported "ejection of sporangia (conidia) from their sterigmata by energy applied at the point of sporangial attachment". Hirst[7] concluded that sporangia (of *P. infestans*) were not removed by wet or dry gales but were dislodged by wetting, rapid changes in relative humidity and strong light. All investigators associated conidiophore movement with an increasing or decreasing relative humidity and spore dissemination with decreasing humidity. Cruickshank[8] reported intensity of spore discharge in *P. tabacina* with change in relative humidity and mechanical shock. In the experiments reported here, factors other than ambient relative humidity were also concerned in spore release.

Dissemination of conidia was investigated at Canberra, Australia, with the aid of a spore trap[9] operated among tobacco plants showing heavy sporulation. In three seasons of field experiments, the number of conidia trapped each hour of the day increased to a maximum between 0930 and 1100 hr. for periods of 12–16 consecutive days. This daily cycle was not interrupted by overnight relative humidity too low for sporulation, the conidia disseminated having been produced at an earlier date. Thus spore release was not conditional on a decreasing humidity being preceded by overnight saturation. This conclusion was confirmed by glasshouse tests in which the relative humidity subsequent to sporulation was maintained at low levels for long periods (Table 1 and Fig. 1). The results of numerous tests show that the number of days in the daily cycle of spore release was least when there was a wide range, and repeated sudden fluctuations, in temperature and humidity. Daily periodicity for 4–10 days was common.

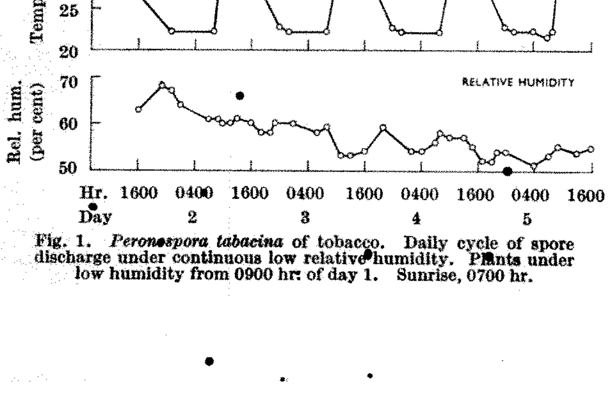

Fig. 1. *Peronospora tabacina* of tobacco. Daily cycle of spore discharge under continuous low relative humidity. Plants under low humidity from 0900 hr. of day 1. Sunrise, 0700 hr.

Table 1. RELATIVE HUMIDITY DURING CONSECUTIVE DAYS AND AT TIMES WHEN NUMBERS OF CONIDIA TRAPPED WERE INCREASING

* From hygrographs among sporulating plants.
† Shaded glasshouse.
‡ Also shown graphically.

Examination of the fruiting structures of the pathogen *in situ* showed that twisting movements of the conidiophores were due to loss of turgidity in the stalk. This was followed by collapse of the branched superstructure, with many conidia still attached to it, on to the leaf surface. Spore release ceased but was resumed from both living and dead leaves on the same or succeeding days following periods of high ambient humidity. The spore trap data also showed that rising temperature, or light following a period of darkness, were associated with spore release. Collapsed conidiophores with attached conidia remained in that state, subsequent movements being restricted to some of the branches. The only method of spore dispersal that occurred either with or without conidiophore movement was, as described by Pinckard, due to "energy applied at the point of attachment".

These results show that spore release is regulated to provide for dissemination at intervals in time. Factors that appear to be responsible for spore release—reduction in relative humidity, increase in temperature, or light—could cause humidity or temperature-humidity changes in the region occupied by the conidiophores and thus ensure a progressive release of conidia. Whatever the mechanism involved, the results clearly show that spore discharge is a response to stimuli repeated at intervals, and that the normal interval was approximately 24 hr. Under this arrangement, conidia were held ready for dispersal and could take advantage of favourable conditions occurring at any time over a period of days following their production.

A full account of the work will be presented elsewhere.

The Lungworm Protostrongylus rufescens in Australia

Of the lungworms described from domestic sheep only two, namely, *Dictyocaulus filaria* and *Muellerius capillaris*, have been identified in Australia[1], despite careful searching in the eastern States[2]. On one occasion a single larva of *Protostrongylus* spp. was found in fæces of a sheep in Tasmania (Gordon, H. McL., personal communication), but earlier records of the adults are regarded as mistaken[1,2].

P. rufescens has now definitely been identified in lungs of sheep from Millicent, in the south-eastern part of South Australia, and its larvæ in fæces from the flock. Larvæ have also been found in the abomasal contents of a sheep from Kojonup in the south-west of Western Australia. The indications from the large numbers of adults recovered (up to 600 in a single sheep) are that the worm is by no means rare in the south-western part of Australia.

The anatomy conforms in detail with that described by Gerichter[3] except that the local adults, eggs and first-stage larvæ are rather smaller; for example, males are 18–30 mm. and females 28–45 mm. long, against Gerichter's 22–46 mm. and 30–65 mm. respectively. Other authorities[4] record dimensions comparable with our measurements.

The surface of the affected lungs showed scattered yellowish grey consolidated patches of irregular shape, 3–15 mm. in diameter, identical with those described by Kassai[5]. The worms were found mostly in clumps of up to ten, obstructing bronchioles, with some lying in larger air-vessels. A rapid and highly effective method of extracting the worms is to fill the trachea and bronchi with saline, tip up and down several times, pour out, and repeat the process a number of times.

The material from Kojonup was kindly made available by Dr. I. W. Parnell, of Perth. We wish to thank Mr. A. W. Banks for advice in connexion with this work.

MICROBIOLOGY

Feedback Control of Tryptophan Biosynthesis

Microbiologists are becoming increasingly interested in the regulation of biosynthesis. There has been a number of reports of normal metabolites inhibiting the action of enzymes necessary for their own biosynthesis[1–6], and others of the inhibition of enzyme formation or activity[7–9]. Umbarger[1,2] has called this type of inhibition 'negative feedback'.

In this laboratory we have been interested in tryptophan biosynthesis, particularly the identification of intermediates in the conversion of anthranilic acid to indoleglycerol phosphate[10]. Moyed and Friedman[6] have recently demonstrated that tryptophan can inhibit the metabolism of anthranilic acid by a cell-free preparation of *Escherichia coli*, and considered that the site of inhibition was the condensation of anthranilic acid with 5-phosphoribosyl-1-pyrophosphate. We considered that this interpretation was premature, since the preparation could carry out more than one step and because N-*o*-carboxyphenyl-D-ribosylamine, the unphosphorylated form of the postulated condensation product, is chemically unstable at biological *p*H (ref. 10 and unpublished work by Doy, C. H.). It seemed to us that the site of inhibition might equally well be the Amadori rearrangement step:

$$\begin{tikzcd} \text{Anthranilic acid} \arrow[r] & \text{N-}o\text{-carboxyphenyl-D-ribosylamine-5-phosphate} \arrow[l, dashed, bend left, "\text{decomposition}"] \arrow[d, "\text{inhibited}"] \\ & \text{1-(}o\text{-carboxyphenylamino)-1-deoxyribulose-5-phosphate} \end{tikzcd}$$

In any event we suspected that anthranilic acid was only formed by the appropriate tryptophan auxotrophs of *Aerobacter aerogenes* and *Escherichia coli* in the absence of growth.

We have now shown (Fig. 1) that *Aerobacter aerogenes* mutant strain *NCW-T-17A*, able to respond to indole, but not anthranilic, acid and known to accumulate anthranilic acid in washed-cell experiments with minimal substrates, does not excrete detectable amounts of anthranilic acid until growth on limiting L-tryptophan has ceased. The coincidence of end of growth and the onset of accumulation suggests that tryptophan is able to inhibit a process necessary for the biosynthesis of its own precursor anthranilic acid. Because there was no lag between end of growth and the excretion of anthranilic acid, the inhibition is likely to be on the action of an enzyme rather than on enzyme formation. This conclusion is supported since cells harvested during growth, washed to remove tryptophan and then transferred to minimal substrate, immediately begin to form anthranilic acid (Fig. 2, but note tendency for acceleration). In fact, they form the intermediate at a faster rate than that observed after growth (Fig. 1). This is probably because the fresh substrate represents a condition closer to the optimum.

The conclusion that tryptophan is able to control its own biosynthesis by inhibiting the action of an enzyme necessary for a stage prior to anthranilic acid suggests that the inhibition reported by Moyed and Friedman[6] is not the earliest site of action and is therefore more of a potential control point than a real one. Since nothing is known of specific tryptophan precursors prior to anthranilic acid, the inhibition now reported makes this part of the pathway particularly important. Because of this lack of knowledge it is also necessary to have reservations about the role of anthranilic acid, since the 'natural' condensation of 5-phosphoribosyl-1-pyrophosphate may be with a compound other than anthranilic acid[11].

Tryptophan auxotrophs grow well if supplied with L-tryptophan, which suggests that tryptophan does not inhibit the biosynthesis of precursors which it shares in common with phenylalanine and tyrosine. It is likely that, as with other examples[3,4], the 'end product' will be found to inhibit the earliest step specific to its own biosynthesis.

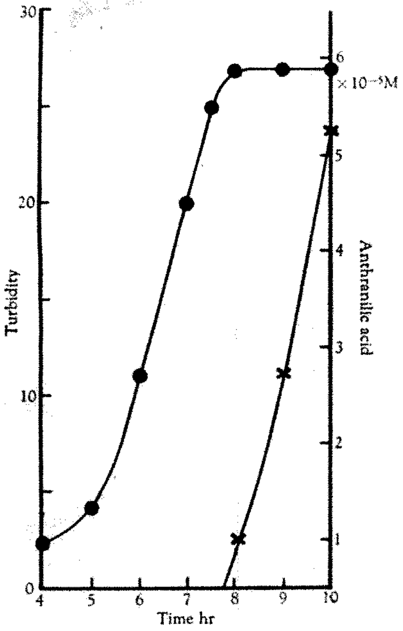

Fig. 1

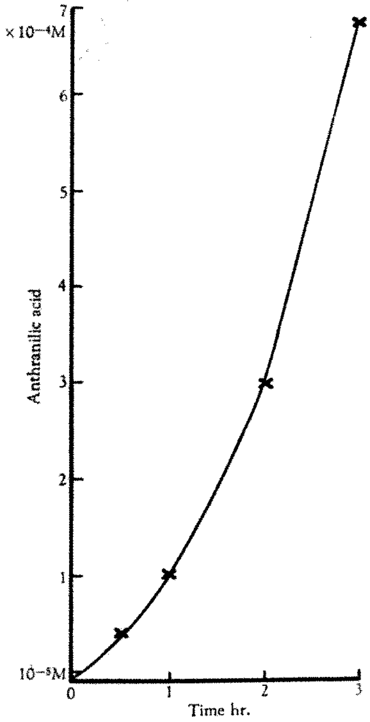

Fig. 2

Fig. 1. Growth of tryptophan auxotroph *Aerobacter aerogenes NCW-T-17A* compared with excretion of anthranilic acid. Minimal substrate, 15 ml. (disodium hydrogen phosphate, 12·8 gm.; potassium dihydrogen phosphate, 2·72 gm.; ammonium chloride, 5·4 gm.; D-glucose, 36 gm.; magnesium sulphate, 10^{-1} *M*, 2 ml.; made up to 2 l., *p*H 7·7) supplemented with 2×10^{-5} *M* L-tryptophan, was lightly inoculated with the test strain and shaken in a ⊥-tube at 37° C. Samples were taken for turbidity measurements (625 mμ filter, 20 = 0·6 mgm. dry wt./ml.) and determination of anthranilic acid by the method of Bratton and Marshall (ref. 12) (slightly less than 10^{-5} *M* was detectable). ●, Growth (turbidity); ×, anthranilic acid; none was detected until 8 hr.

Fig. 2. Growing cells (Fig. 1) harvested at turbidity 20, washed and resuspended in minimal substrate to equivalent turbidity, then shaken in ⊥-tube at 37° C.

Growth of Iron Bacteria in Crude Tar

In continuous distillation units of the Midland Tar Distillers, Ltd., in which vertical retort gas tar was distilled, it was found that certain heat exchangers pre-heating the crude tar became rapidly choked with deposits of fibrous material. It was at first thought that this was adventitious material such as asbestos or vegetable fibres present in the crude tar feed with entrained particles of solid material. The crude feed was, however, continuously filtered through a 'Rotoclene' filter with a clearance of ten-thousandths of an inch and examination of the material held back by this filter did not resemble the deposit within the heat exchanger. It was this fact, together with the quantity and consistent appearance of the deposit at one point in the heat exchanger train, that suggested, in fact, it was essentially a growth in the tar medium.

The fibrous matter in the deposit was demonstrated to be neither asbestos nor vegetable, and an analysis of the ashed deposit showed it to consist mainly of iron oxide and manganese salts. Under the microscope, iron oxide skeletons were readily discernible among the ash, which suggested that the deposit may at least in part have been due to biological growth. The ash was also strongly paramagnetic, which lent weight to this view, as the production of a magnetic form of iron oxide is characteristic of the activity of iron bacteria.

Samples of a freshly collected deposit were examined under the microscope. Dense populations of motile bacilli and cocci were observed, and, in addition, what appeared to be fungal filaments with multi-cellular structure with branching and spores at the branch ends were also noted. The diameter of the fibres was about 20 microns, which although larger than that of most observed filamentous bacteria, is still within the range of size of filamentous bacteria.

The suggestion, therefore, was that the prime reason for the formation of the deposit was the development of iron bacteria. Conditions in the heat exchanger were favourable for the growth of diverse species of micro-organisms. The temperature-range over the section in which the deposit was prevalent was 30–70° C.

When the quantity of iron present in the deposit was considered, it did not seem reasonable that this iron was a result of corrosion, because gross corrosion of the heat exchanger was not taking place. It seemed more reasonable to assume that the iron oxides had come from a concentration of the soluble iron salts present in the crude tar either by biological activity or purely physical and chemical means.

The deposit also contained 3·0 per cent (w/w) of sulphides, and as only a trace of sulphur was present in the crude tar feed (as thiosulphates, thiocyanates, sulphates), here again was a process of concentration to be explained either by biological or physical and chemical means.

The mild conditions in the heat exchangers and the significant temperature-range (30–70° C.) pointed to biological activity as the prime cause of the deposit.

The cultivation of iron bacteria outside their normal environment is difficult, but a reasonable amount of 'fibrous' organism was grown on a solid medium which included an aqueous extract of the deposited material. Although the filaments could not be positively identified, their appearance agreed with descriptions found in the literature of some of the iron bacteria. They did resemble the fibres actually present in the heat exchanger deposits, so far as magnetic properties, appearance and sulphide content were concerned.

It is possible that the small motile vibrio type of organisms observed under the microscope in fresh samples were sulphate-reducing bacteria, but this has not yet been confirmed.

I wish to thank Dr. N. J. Cartwright and Mr. F. W. Moore, of the Department of Bacteriology, University of Birmingham, for their interest and assistance on the microbiological side.

Observations on the Nagler Reaction of some *Clostridia*

NAGLER[1] showed that the surface of colonies of *Clostridium oedematiens* type *A* growing on egg-yolk – sheep-blood agar, is covered by a pearly layer. Subsequent investigations by McClung *et al.*[2] and McClung and Toabe[3] showed that this phenomenon was not restricted to *Cl. oedematiens* type *A*, but was also shown by all types of *Cl. botulinum* and by *Cl. sporogenes*, and was more evident if the blood was omitted from the medium. All the *Clostridia* which show this pearly layer on egg-yolk agar also produce an opalescence within the medium, somewhat similar in appearance to that produced by anaerobes such as *Cl. welchii* and *Cl. bifermentans*, which produce lecithinase. Oakley *et al.*[4] showed that cultures and culture-filtrates of *Cl. oedematiens* type *A* produce two distinct types of opalescence in egg-yolk emulsions: a diffuse opalescence due to a hæmolytic lecithinase (*Cl. oedematiens* γ-toxin), and a more confined opalescence due to a lipase (*Cl. oedematiens* ε-antigen). They suggested that the pearly layer also produced by *Cl. oedematiens* type *A* might be caused by the lipolytic ε-antigen (see also ref. 5). Sussman (personal communication) showed that cultures of *Cl. sporogenes* were lipolytic when grown on tributyrin agar ('Oxoid'), and that this organism developed a pearly layer when grown on an agar medium containing triolein.

The present communication presents briefly the results obtained in a study of the pearly layers produced by *Cl. sporogenes*, all types of *Cl. botulinum* and *Cl. oedematiens* type *A*.

A number of clostridia were examined for lipolytic activity by growing them as surface cultures on tributyrin agar ('Oxoid') enriched with 5 per cent of Fields's extract of red cells. Lipolysis, indicated by the development of zones of clearing in the medium about areas of growth, was shown by strains of *Cl. sporogenes*, all types of *Cl. botulinum* and *Cl. oedematiens* type *A*, but not by strains of *Cl. bifermentans*, *Cl. welchii* (types *A–F*), *Cl. histolyticum* or *Cl. oedematiens* type *B* (see Table 1). Thus, of the species examined, only those which produce a pearly layer on egg-yolk media showed lipolytic activity on tributyrin agar.

Table 1. ACTION OF SOME *Clostridia* ON MEDIA WITH AND WITHOUT LECITHIN AND FAT

Organism	Clearing on 'Tributyrin' agar	Egg-yolk agar		Cream-milk agar		Fat-free milk agar	
		Opal.*	Pl.†	Opal.	Pl.	Opal.	Pl.
Cl. welchii (*A–F*)	–	+	–	–	–	–	–
Cl. bifermentans	–	+	–	–	–	–	–
Cl. histolyticum	–	–	–	–	–	–	–
Cl. botulinum (*A–E*)	+	+	+	+	+	–	–
Cl. sporogenes	+	+	+	+	+	–	–
Cl. oedematiens, type *A*	+	+	+	+	+	–	–
Cl. oedematiens, type *B*	–	+	–	–	–	–	–

* Opal., opalescence. † Pl., pearly layer.
+ or –, present or absent, respectively.

The various organisms were then cultured on egg-yolk agar, full-cream-milk agar and fat-free-milk agar. The results, which are summarized in Table 1, show that all the lipolytic organisms examined produced an opalescence and a pearly layer on fat-containing media, but not on the fat-free medium. Lecithinase activity was shown only on egg-yolk agar.

Egg-yolk agar plates, full-cream-milk agar plates and fat-free-milk agar plates were spotted with pancreatic lipase (Light and Co.) and incubated at 37° C. The egg-yolk and cream plates developed zones of opalescence covered by a pearly layer, similar in appearance to those produced by the lipolytic *Clostridia*. No opalescence or pearly layer was produced by pancreatic lipase on the fat-free medium. These plates, and all the plate cultures of the anaerobes, were flooded with a saturated solution of copper sulphate, allowed to stand for a few minutes, and then rinsed with water (the copper soap test for lipase). Positive results, shown by the appearance of bluish-green zones of precipitate in the medium, were given by the egg-yolk and cream plates treated with pancreatic lipase, and by all the cultures of *Clostridia* growing on egg-yolk and cream agar and producing a pearly layer. Negative results were given by cultures not associated with a pearly layer.

These results indicate that the pearly layer and opalescence produced on egg-yolk and other fat-containing media by the *Clostridia* examined are due to lipolytic activity, and probably consist of free fatty acid. No pearly layer is produced on tributyrin agar by lipolytic organisms because the products of lipolysis (glycerol and butyric acid) are soluble. Macfarlane suggested[6] that *Cl. oedematiens* type *D* (*Cl. hæmolyticum*) may produce traces of a lipase. This organism has not been studied in the present investigation.

If the conclusions drawn are correct, it seems likely that the butyrous scum which sometimes develops on the surface of cooked-meat broth cultures of *Cl. botulinum* and *Cl. sporogenes* consists of fatty acid liberated by lipolysis. Further, the absence of a lipase from cultures of *Cl. welchii* provides an explanation for the characteristic fatty appearance of the œdema fluid produced in pure *Cl. welchii* gas gangrene.

Further investigations along these lines are at present being made and will form the basis of a subsequent more detailed communication.

Survival of Bacteria on Drying in Sugar/Protein Mixtures

In an investigation of the protection afforded by various sugars in the preservation of the viability of dried cultures, Hellier[1] directed attention to the advantage of a sucrose/peptone mixture over either sucrose or peptone alone. In 1951, Fry and Greaves[2] proposed their *mist. desiccans*, a serum/broth mixture containing 7·5 per cent glucose, and this has come into extensive use as a medium in which to dry a wide variety of organisms with a high retention of viability. In general, in the presence of either sugar or protein alone, the percentage survival is relatively poor; only in a mixture of the two in suitable proportions and in adequate concentration is a high degree of viability retained after drying and reconstitution. The underlying action of such mixtures has not hitherto been satisfactorily explained.

The concept of a bacterial cell as confined by a thin plasma membrane supported by an outer, stronger and more permeable cell wall is now well established, and the phenomenon of plasmolysis as displayed by various Gram-negative organisms on exposure to solutions of electrolytes and sugars such as glucose or sucrose has long been recognized as the result of the collapse of the plasma membrane due to osmotic forces caused by these substances, to which only the cell wall is permeable. During such plasmolysis the overall shape of the cell as defined by the cell wall is still clearly seen.

By the use of a micro-culture chamber[3] we have observed that cells of *Bacterium coli* dried in various sugar solutions, or even after exposure for some time to their concentrated solutions, exhibit, on returning to ordinary growth media such as broth or peptone water, a high proportion of spherical forms or protoplasts resulting from the rupture of the cell wall by the high diffusion pressure set up by the sugar temporarily trapped between the cell wall and plasma membrane. This cell wall damage can be to a large extent averted and the normal morphology and viability retained if the sugar-treated cells are returned to normal media gradually through progressively decreasing concentrations of sugar. We have evidence to suggest that the main function of the sugar in preserving viability on drying lies in its ability to preserve the cell wall intact.

The cell wall, though permeable to mono-, di- and tri-saccharides, is impermeable to proteins and to partially hydrolysed proteins such as constitute a proportion of broth, peptone, etc. By measurements of cell volume we have been able to show that the relatively mild osmotic forces exerted by such substances of higher molecular weight against the cell wall cause its contraction against the plasma membrane and thereby reduce the volume between the two. Thus, when organisms are dried in a mixture of suitable high and low molecular weight components in adequate concentration, the latter will afford protection to the cell wall on drying while the former will limit the amount of the low molecular component inside the cell and thereby reduce the risk of cell wall rupture on reconstitution.

A more detailed account of this work will be published.

GENETICS

Effect of Selection on the Frequency of Genotypes determining Incompatibility in *Prunus avium*

An analysis of the frequency of alleles at the 'S' locus[1] in cultivars of *Prunus avium* indicated that the S_3 allele possessed a selective advantage. Since gametic selection does not appear to operate in this material, and since heterozygosity at the S locus is obligatory, it is of interest to inquire whether selection favours certain genotypes showing inter-allelic interactions, quite apart from the individual alleles they contain. In the absence of genotypic selection, the expected number of varieties of the type S_iS_j is of the form m_im_j. Calculation of an exact value of P for the actual frequencies (Gale, J. S., unpublished work) of the various genotypes is impossibly laborious, but it is possible to set an upper limit to the probability of obtaining by chance a fit as bad as, or worse than, the one observed.

If a_{ij} is the number of varieties of the type S_iS_j, the probability of getting the observed result is:

$$\frac{\dfrac{65\,!}{\pi(a_{ij}!)}\ \pi\left(\dfrac{m_im_j}{65}\right)^{a_{ij}}}{\sum\limits_{\text{all cases}} \dfrac{65\,!}{\pi(a_{ij}!)}\ \pi\left(\dfrac{m_im_j}{65}\right)^{a_{ij}}} = \frac{C}{\sum\limits_{\text{all cases}} C}$$

where $C = \dfrac{1}{\pi(a_{ij}!)}$ and summation is over every way of filling the table, given[1] $a_3 = 42$, $a_1 = 32$, $a_2 = 25$, $a_4 = 15$, $a_5 = 9$ and $a_6 = 7$, where a_i is the observed number of S_i alleles. If C_0 is the value of C for the observed case:

$$P = \frac{\sum\limits_{C \leqslant C_0} C}{\sum\limits_{\text{all cases}} C}$$

and it can be shown (Gale, J. S., unpublished work) that $\sum\limits_{\text{all cases}} C = 337{,}850{,}000\ C_0$ and that the number of cases is 3,693,833, so that $\sum\limits_{C \leqslant C_0} C$ cannot exceed 3,693,833 C_0 and

$$P \leqslant 1{\cdot}0933 \text{ per cent}$$

This upper limit of probability strongly suggests that the observed frequency can be attributed to selection operating on the genotype, and that certain combinations of alleles, in particular $S_1 S_3$, $S_2 S_3$ and $S_1 S_2$, have been favoured in the course of the improvement of the sweet cherry.

Irrespective of whether this effect is due to inter-allelic interactions, or whether more extensive chromosome regions are involved, its significance for plant breeding is obvious. Furthermore, this result clearly demonstrates the response to selection of characters that might otherwise be classified as neutral to the forces operating, and underlines the importance of selection pressure[2] as opposed to genetic drift[3] in determining the frequency of Mendelian characters.

Chromosomes of South American Amphibians

THE amphibian anurans constitute very interesting material, not only for the cytogenetic study of the evolutionary mechanism of sex determination, but also because they offer prospects from the evolutionary, phylogenetic and cytotaxonomic points of view.

South American species offer a wide scope for investigation due to their abundance and their distribution in different geographical regions of the Continent.

The only species which have been studied up to the present are: *Bufo arenarum* (Hensel)[1] and *Dendrophrynicus stelzneri*[2] which are representatives of the families Bufonidae and Brachycephalidae respectively.

With the view of extending this investigation, we have studied other species belonging to different families (Table 1).

Table 1

Species	Family	Diploid No. ($2n$)	Type of chromosomes
Bufo d'orbignyi	Bufonidae	22	Metacentrics
Odontophrynus americanus	Ceratophrydae	42	Metacentrics
Ceratophrys ornata	Ceratophrydae	88, 92, 98, 108	Metacentrics
Leptodactylus ocellatus	Leptodactylidae	22	Metacentrics
Pseudopaludicola falcipes	Leptodactylidae	22	Metacentrics
Pseudis paradoxa	Pseudidae	22	Metacentrics
Hyla raddiana raddiana	Hylidae	24	Metacentrics

Hyla raddiana raddiana presents, during the first meiotic metaphase, a differential bivalent, that differs from the rest of the autosomes, and is similar to that described in *Bufo arenarum* by one of us[1]. We did not attribute the characteristics of sex chromosomes to their bivalent as Yosida does[3] in a recent paper. The most remarkable fact observed by us is the high number of chromosomes in *Odontophrynus americanus* and *Ceratophrys ornata*.

Odontophrynus americanus has the highest number of chromosomes in an anuran described up to now. *Ceratophrys ornata* is unique among all the amphibians, urodeles and anurans, known up to the present for their high number of chromosomes.

From the cytotaxonomic and evolutionary points of view the taxonomic position of the two genera presents a problem, since they have been considered by Noble[4] as belonging to the family Bufonidae and by Davies[5] to the family Leptodactylidae, the karyotype of which is characterized by a diploid number of $2n = 22$ chromosomes. We suggest that the genera *Odontophrynus* and *Ceratophrys* should be included in a different group, as they appear in the amphibian list published by Cei[6] but forming part of the family Ceratophrydae.

In all the species described here, the chromosomes of the first meiotic metaphase were found to be highly condensed, with two distal localized chiasmata. The primitive annular configuration exhibited by the bivalents during the diplonema remains masked at the moment of the metaphase. None of the species studied shows sex chromosomes that could be differentiated by cytogenetical analysis.

Our observations thus support the views of Galgano[7], Saez *et al.*[8] and Wickbom[9], with reference to the problem of the existence of sex chromosomes in the amphibians.

ANTHROPOLOGY

The Kanam Jaw

SINCE Dr. and Mrs. L. S. B. Leakey discovered that the Oldowan pebble tool-maker in Tanganyika was an Australopithecine (*Zinjanthropus boisei*)[1], I have been frequently asked whether this development has any bearing on the unsolved problem of the Kanam mandible which was recovered by Dr. Leakey in 1932 from deposits in Kenya apparently at the same cultural horizon as the newly discovered Olduvai skull. The Kanam mandible was referred to *Homo kanamensis* sp. nov.[2] and is preserved in the British Museum (Natural History).

As the Kanam mandible has small front teeth and an apparent chin it was regarded by some authorities as indicating the existence of the modern type of man in Lower Pleistocene times, but Prof. P. G. H. Boswell, having formed the opinion in the field that the geological age of the specimen was not beyond doubt, suggested that it should be placed in "a suspense account" pending further discoveries[3].

Attempts have been made during recent years to establish whether the Kanam mandible was or was not contemporaneous with Lower Pleistocene fauna at the site of discovery; but in summary the results were ambivalent. In volcanic soils, particularly under tropical conditions, the chemical dating methods are admittedly unreliable. In 1952 I pointed out that the fluorine/phosphate ratio of the Kanam mandible was higher than that of any fossil bone that had been tested[4]; yet in 1958 radiometric assays (for adsorbed uranium) gave results which led me to write "our doubts about its antiquity have been re-inforced"[5]. But those doubts were primarily morphological in basis.

Prof. P. V. Tobias, of the University of the Witwatersrand, has recently re-investigated the morphology of this mandible with particular reference to the apparent chin or mental eminence (see following communication). Meanwhile, I wish to direct attention to a fact which may have escaped notice. Sir Arthur Keith in 1948 had come to the conclusion that the Kanam mandible was probably Australopithecine. This is what he wrote: "Dr. Leakey believed, and I agree[d] with him, that the Kanam mandible was evidence of the early development of the modern type of man. Both he and I were then ignorant of the fact that small incisors and canines were also characteristic of the South African Dartian anthropoids [Sir Arthur Keith's name for Australopithecines]. It seems to me now to be much more probable that the small front teeth of Kanam man indicate a relationship to Dartian anthropoids rather than to any type of modern man"[6].

[6] Keith, Sir Arthur, "A New Theory of Human Evolution", 261 (1948).

THE controversial mandibular fragment from Kanam in Kenya Colony has long been placed in a 'suspense account' by most palæo-anthropologists. There is little doubt that the presence of an ostensibly well-developed chin in this fossil, for which a Lower Pleistocene age was claimed[1], proved a difficult pill to swallow. As long as the over-simplified notion prevailed that a chin signified *Homo sapiens* and, as long as the Kanam fragment was deemed to possess a chin, one had to explain the unexpected presence of *Homo sapiens* in a Lower Pleistocene deposit or discard either the dating of the deposit or the association of the jaw with the deposit.

In 1955, I was granted permission to re-examine the jaw fragment by the British Museum (Natural History) and, in particular, by Dr. K. P. Oakley and by Dr. L. S. B. Leakey. On first examining the specimen I was struck by two previously unreported facts: first, the 'chin' was represented by an asymmetrical fullness situated largely to the left of the symphyseal surface which had earlier been diagnosed as a "sub-periosteal ossifying sarcoma"[2]. The possibility that the 'chin' was in reality largely a bony reaction to the pathological lesion was heightened by the second observation, namely, that of the elements comprising the mental trigone normally sculptured on the front of a chin, the mental tubercles were completely absent and the mental protuberance was extremely poorly developed. Clearly a detailed morphological re-analysis was essential, and the results of such a study were presented by me at the fourth Pan-African Congress on Prehistory in August 1959[3]. The detailed account will appear in the Proceedings of that Congress.

As a result of the study, I have reached the conclusion that the chin of Kanam man has been greatly over-estimated. In fact, I am convinced that the Kanam fossil does not represent a sapient type of man, but rather belongs to a group of fossils from Africa, known variously as 'palæoanthropic', 'neandertaloid' or 'rhodesioid'. None of the characteristics originally used to define the structure of *Homo kanamensis* (to which the specimen was earlier assigned)[4] is morphologically valid, and the species designation must therefore lapse. On the other hand, a different series of primitive features has impressed me in the re-study. These are:

(1) The great depth in the symphyseal region (40·5 mm. as measured, at least 42·0 mm. as estimated), aligning Kanam with such primitive forms as *Pithecanthropus*, *Atlanthropus*, Mauer and Wadjak, as well as with Cro-Magnon man and several fossils from South and East Africa.

(2) The tremendous depth in the region of M_1 (at least 40·0 mm.), in which respect Kanam exceeds all other mandibles with which it was possible to compare it.

(3) The lack of tapering in body-height between symphyseal and molar regions, which likens the Kanam jaw to those of *Sinanthropus* and *Atlanthropus*, including Sidi Abderrahman.

(4) The very great thickness in the region of M_1 (16·5 mm.), in which feature Kanam is exceeded only by Ternifine I, Heidelberg and Sidi Abderrahman, while it is more or less equal to Ternifine II, *Sinanthropus* G.I., Rabat, Dire-Dawa, Cave of Hearths and La Chapelle.

(5) The rudimentary character of the two elements of the chin present, namely the mentum osseum and the mental protuberance, as in the mandibles of La Quina, La Ferrassie, Spy and Rabat.

(6) The presence of a planum alveolare and of a genial fossa and inferior transverse torus, as in Rabat and Dire-Dawa.

(7) The combination of very small incisors and rather large canines, a likeness with some of the Australopithecinae to which Keith directed attention in 1948, as pointed out by myself at the fourth Pan-African Congress on Prehistory in August 1959 and by Dr. K. P. Oakley (see previous communication).

Several, though not all, of these features might be encountered individually as exceptional variants among modern African mandibles. However, the ensemble of features in a single mandible tends to exclude the Kanam jaw from the *Homo sapiens* group and to relate it rather to a group of earlier African fossil men. Its morphological features align it most closely with the Upper Pleistocene mandible from Dire-Dawa, in the Harrar District of Abyssinia[5], and the Middle Pleistocene Rabat fragment from the

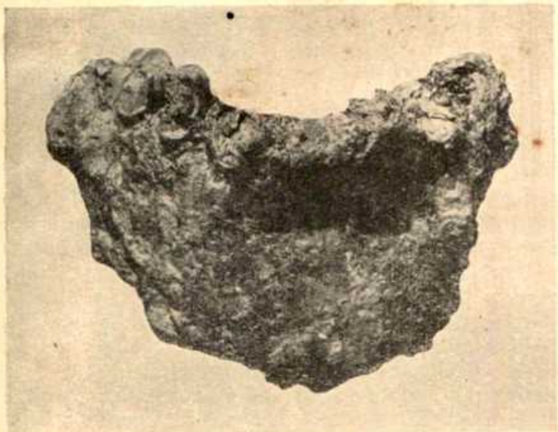

Fig. 1. The Kanam mandible. The fullness of the so-called chin is seen on the right, clearly demarcated by a highlight. The sockets and roots of the missing teeth are apparent; the surviving two right premolar teeth can be seen

Atlantic seaboard of Morocco[6]. On the other hand, the Ternifine mandibles of *Atlanthropus* show more archaic features than do those of Kanam, Rabat and Dire-Dawa; while the Kanam mandible has several morphological features comparable with those of Sidi Abderrahman, though the crucial evidence of the chin region and the retro-symphyseal surface is lacking[7]. As to the possibility of australopithecine affinities, the main resemblance is in the size proportions of the front and back teeth. A few ape-man specimens have, in addition, a degree of chin development faintly reminiscent of that of Kanam.

Thus, while we cannot entirely exclude the possibility that the Kanam jaw is related to a member of the Australopithecinae or of *Atlanthropus*, the balance of evidence supports the view that the Kanam mandible represents a third African fossil showing a cluster of features morphologically intermediate between those of *Atlanthropus* and those of modern man. Whether or not it is justifiable to describe these forms as neandertaloid, thereby relating them by implication to European forms, is a problem which must await more material and further analysis.

At least, it is no longer necessary or correct to build theories upon the alleged 'sapient' or 'modern' morphology of Kanam man; nor should the specimen be interpreted as providing evidence in favour of the *presapiens* theory espoused by Vallois[8]. Perhaps most importantly of all, we are now in a position to consider the age of the Kanam specimen, free from any misconceptions that it is of sapient character.

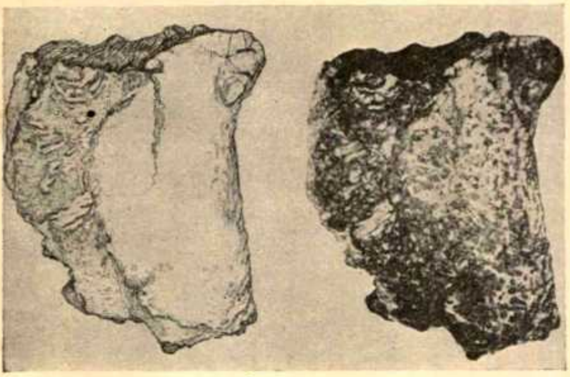

Fig. 2. Sketch and photograph of a section through the Kanam mandible, to show the large pathological mass on the retrosymphyseal surface. The section has passed through the right first incisor root

Fossilized Human Remains from Northern Kenya

DURING the summer of 1959, a party from the Durham Colleges visited the remote district of Turkana in northern Kenya to carry out a geological survey of the Lothidok and the Labur ranges of hills, which border the western shore of Lake Rudolf.

The rocks which compose the Lothidok range are probably Miocene; but a thick sequence of younger lacustrine sediments is developed against the eastern flank of the Lothidok range, immediately south of the Kalalokoil River (approximate position 35° 47′ E., 3° 26′ N.). C. Arambourg[1] has stated that their age is Upper Pleistocene. These lacustrine beds represent deposition in an ancient Lake Rudolf of far greater extent than the existing lake, since they stand between two hundred and three hundred feet above present lake-level. In places, the Miocene lavas and agglomerates of the Lothidok range must have formed a rocky shore-line to this ancient lake, during a part of Pleistocene times. From the western marginal facies of the lake beds, adjacent to their contact with the Miocene, the Durham Colleges party recovered portions of two fossilized human skulls which are the first remains of this kind to be found in the northern region of Kenya. One is represented by little more than the frontal bones and the upper margins of the orbits. The other skull, with which this communication is chiefly concerned, lacks only the face and the left side of the jaws. A few cervical vertebræ and ribs, and part of a humerus were intimately associated with the second skull.

The more complete skull has been slightly distorted during its enclosure in the lake sediments, but it is possible, without further preparation, to distinguish certain salient features of the skull. The cranial bones, which, incidentally, are fully lithified, are unusually thick (12 mm. or more). The skull is long and conspicuously narrow, although the latter character is exaggerated by crushing; and the face appears to have been small. There is no more than a suggestion of a supra-orbital torus, but the brow is remarkably low. The lower jaw (Fig. 1) is very robustly constructed, with a deep horizontal ramus 22 mm. thick below the third molar; and the mandible seems to have possessed a chin. The molar teeth are very badly worn, being planed down almost to the level of the inferior margin of the enamel. They

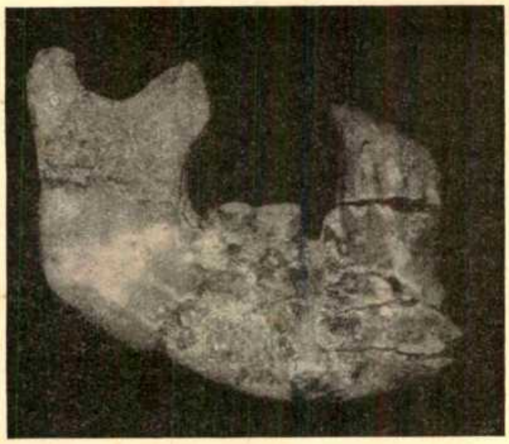

Fig. 1. Lateral aspect of the right branch of a fossilized human mandible, together with a fragment of the upper jaw; from Turkana, northern Kenya (half natural size)

are probably a trifle larger than is the average in Recent individuals of *Homo sapiens*.

Numerous artefacts were found afterwards on sites adjacent to this fossilized human skull, but all were surface finds. None was found *in situ*. The implements include Middle Sangoan hand-axes and Levallois-type flake tools fashioned in chert, small stone points of Solutrean aspect, and barbed harpoon heads and spatulæ of bone. Neighbouring sites also yielded rather poorly preserved remains of various fossilized mammals, including hippos, antelopes and pigs, as yet not properly identified.

It is too early to speculate upon the nature or status of the skull, but there seem to be some clear physical resemblances to the most complete of the Kanjera skulls, which were recovered by L. S. B. Leakey nearly thirty years ago from Pleistocene lake beds developed on the flank of Homa Mountain in western Kenya. Dr. Leakey has suggested a Middle Pleistocene date for the Kanjera skulls. So far, it has not been possible to establish with certainty the precise stratigraphical position of the human fossils from Turkana. Attempts to obtain an absolute dating by chemical methods have also proved inconclusive. The uranium content is the same in both the human bones and in fossilized animal bones from neighbouring sites, which are believed to be undoubtedly contemporaneous with the formation of the lake beds, but the actual figure for all this material is abnormally low.

PSYCHOLOGY

Age Differences in Movement Pattern

THE literature which describes studies of detailed hand movement patterns contains few references to changes in acceleration during these movements. Such references as do occur are mainly to be found in books on motion study and suggest that a movement occurs in three phases: an acceleration phase to a steady speed, followed by deceleration. For example, Lowry *et al.*[1] give a curve purporting to show this pattern without quoting any evidence to support it. Experimental work carried out here[2] and at Cambridge by Singleton[3] suggested that movement patterns of older people might differ from those of young and, since no relevant evidence could be found in the literature, an ultra high-speed chrono-cyclographic technique was developed in order to make a detailed study of movement patterns.

Our subjects were required to make simple movements in response to a four-choice stimulus and these were photographed with a light on the hand flashing at 100 flashes per second. Three conditions of response were used which differed only in the manipulation demanded after the initial movement was completed. Matched groups of 12 younger subjects (20–25 yr.) and 12 older subjects (60–65 yr.) were used. It was found that under the conditions of this experiment the movement, far from showing a simple acceleration : constant speed : deceleration pattern, showed marked variations in acceleration throughout. Typically, instead of the smooth acceleration which might have been expected, the movement pattern showed very rapid acceleration at the outset, followed by an equally rapid decrease in acceleration to a minimum at approximately 0·1 sec. from the commencement of the movement, which was in turn followed by a second acceleration to a 'peak' of approximately half the value of the first. This whole phase occupied approximately a third of the total movement time. While the characteristic pattern at the outset of the movement was found in both young and old subjects, the old subjects accelerated less rapidly than the young and the 'dip' passed below the zero acceleration line showing that the older men had a short negative acceleration phase. Fig. 1 shows a typical velocity curve for an older subject with the acceleration curve derived from it. There were, within the young and old groups, no statistically significant differences between the three response conditions tested, but between groups there were significant differences in response initiation time in

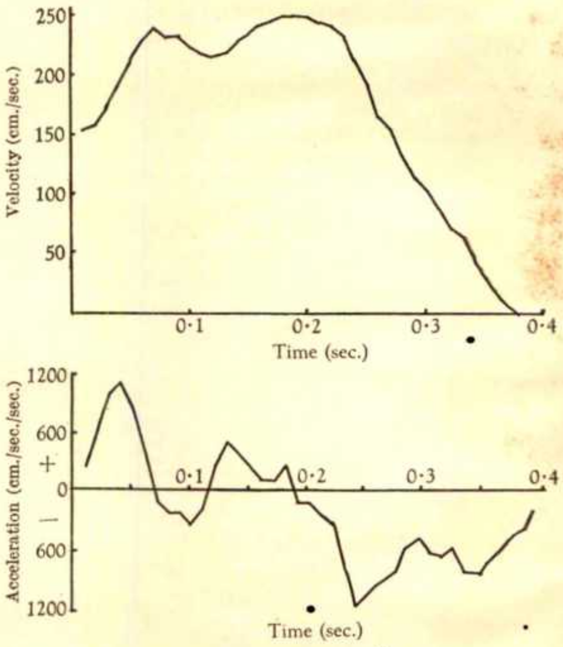

Fig. 1

two of the conditions. Movement times were not significantly different. The magnitude of the initial acceleration and the depth of the 'dip' were significantly different between young and old.

This typical pattern does not appear to occur when a 'free' movement is made in the subject's own time and no stimulus is given or specific response demanded. This suggests that the 'dip' in the initial phase of a 'controlled' movement is in some way associated with either the presence of the visual stimulus or the need to make a response, or both. 'Free' movement patterns do, however, show cyclic periods of acceleration, which are also to be found in the latter two-thirds of the 'controlled' movements. There is a possibility that these may be similar to the oscillations of a particular frequency which have been reported in muscular tremor and static pressure by a number of workers (for example, Hammond *et al.*[4]). If this is so then it would appear that this periodicity will occur in 'free' movements as well as in the static condition.

These results suggest several theoretical possibilities, but the techniques used in this pilot experiment were not sufficiently precise for us to obtain all the information we would need to establish a theoretical model. Work is therefore proceeding with further refined techniques.

Experimental Evidence for Extra-Sensory Perception

IN his communication in *Nature* of November 7, p. 1515, Mr. C. E. M. Hansel cites certain results from the Shackleton experiments in precognitive telepathy which he claims support his theory that the guessers made 'card substitutions' on pre-arranged positions on the scoring sheets. In a forthcoming paper in the *Proceedings of the Society for Psychical Research*, I have shown on quite other grounds how extremely improbable it is that such a method was used. I cannot accept Mr. Hansel's arguments based on the 1,139 (+ 2) trials carried out at rapid rate, because, as I shall show, he makes an unwarranted assumption.

What Mr. Hansel has brought to light in his communication is a most interesting 'segmental salience' effect which had previously escaped notice. Card guessers, as a rule, naturally think of a run of 25 trials as being broken up into five successive groups or 'segments' each of five trials. Most scoring sheets have a thick line, drawn after trials 5, 10, 15, 20 and 25. Subconsciously, many guessers tend to envisage their work as a succession of smaller tasks or separate experiments, each consisting of five trials. Now ever since the year 1941, Prof. J. B. Rhine and his colleagues at Duke University have observed that many percipients tend to distribute their 'hits' according to more or less regular patterns throughout the five guesses of a segment, or in the five segments of a run of 25. Three main types of 'salience' have been distinguished: (*a*) 'terminal' salience in which, in the composite pattern of a segment, the first and last trials score above chance expectation while the three middle trials give a score at about 'chance' level or below it; (*b*) 'middle' salience in which the two end trials give scores at, or below, chance expectation and the three middle trials score above 'chance' level; (*c*) 'decline' salience in which, say, the first three trials are well above 'chance' expectation, after which a decline sets in and the score falls to 'chance' level through the last two trials. Similar 'salience' patterns may occur either in the pooled scores of the five trials of the segment or in the five segments of the run, or 'segment' and 'run' salience may occur together, in which case there is sometimes a high degree of positive correlation between them.

These same patterns have been observed during thousands of trials, as, for example, in the long-distance experiments of Dr. Marchesi[1] in which 'middle' salience occurred both in the segment and run over a series of 8,825 trials. It has been noted in 'precognitive' as well as in 'direct' target-guessing.

The Shackleton (+ 2) *trials*. In order to clarify the issue, I shall neglect the 144 trials which occur in positions Nos. 21, 22, 23 of the scoring sheet of 23 (+ 2) trials, since these do not form complete segments. This leaves us with a total of 995 (+ 2) trials in places Nos. 1–20. On these there are 297 (+ 2) hits which are pooled and distributed over the five successive positions in the segment as in Table 1.

Table 1

Position	Trials	Hits	Deviation*	'Odds' against chance
I	199	61	4·2 × S.D.*	> 1·6 × 10^4 to 1
II	200	72	5·6 × S.D.	> 2·6 × 10^7 to 1
III	200	70	5·3 × S.D.	> 1·7 × 10^6 to 1
IV	198	51	2·0 × S.D.	20 to 1
V	198	43	0·6 × S.D.	—
Totals	995	297	—	—

* S.D., standard deviation = $0{\cdot}4\sqrt{n}$, where n is number of trials Expected score, $n/5$.

It is seen that the scoring-rate reaches a peak at Trials II and III, and afterwards declines to the chance-level. It would appear that at the 'rapid' rate of calling, the extra-sensory perception effect is temporarily exhausted after the third trial, and recovers at the start of the next segment (see Fig. 1). On the first three trials there is a total of 203 hits in 599 (+ 2) trials, as compared with a total of 94 hits in 396 (+ 2) trials. The 'salience' in the segment is mainly of type (*C*), and represents a kind of 'position' effect.

So common were these 'salience' effects in the 'segment' or the 'run' that in 1941 Dr. J. A. Greenwood[2] developed a most elaborate statistical method for evaluating 'salience ratios' and they were even employed as a means of detecting the presence of extra-sensory perception in cases where the deviations from chance expectation in an experiment were not in themselves significant[3]. The assumption is that in certain cases extra-sensory perception produces both positive and negative deviations which may cancel each other out in the long run.

By using Fisher's method for evaluating the significance in the difference of the means of two small samples, I find that the odds against the hypothesis that the difference in the scoring-rates of the two groups (I, II, III) and (IV, V) is due to

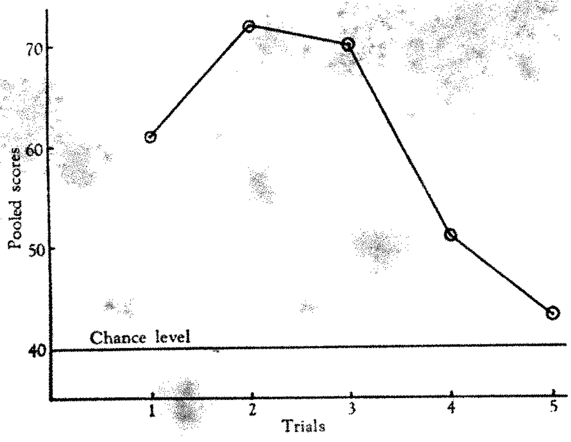

Fig. 1. Score pattern in segment

chance certainly far exceed 1,000 to 1 and are probably of the order of 10^4 to 1, as checked by a different method. The five segments of the run considered as five different units, however, exhibit no evidence of salience; that is, there is not a decline effect in the run itself.

Now the fundamental 'null' hypothesis on which Mr. Hansel has based his expectations of hits and misses in the five trials of the segment is the assumption that, even when extra-sensory perception is functioning at a high level, there ought to be approximately equal numbers of hits (or successes) on equal numbers of trials selected from different pre-assigned positions on the scoring-sheet. But the numerous 'decline' effects observed in both the run and the segment by American investigators show that this assumption is not justified. Further, it has been the experience of Mr. G. N. M. Tyrrell and others that with high scoring subjects such as Miss Johnson, the 'hits' often crowd themselves into unbroken runs of as many as 7 or 8 or more in a run. That is, extra-sensory perception does not function continuously but in spurts. In other words, given a fixed number of hits, these are often found not to be randomly distributed over the 25 cells of the scoring-sheet, but to favour certain positions in the segment or run or in relation to one another.

The 'periodic' effect cited by Mr. Hansel is the result of the 'salience' pattern and constitutes evidence that such a pattern exists that is, on the average, repeated from segment to segment. Similarly, the high scores on the mid-segment trial are simply due to the fact that the peak of the salience happens to coincide with the mid-segment trial and the one preceding.

If an extra-sensory perception salience effect exists, it follows that there may be significantly differing numbers of hits on the different trials of the segment.

Once the existence of extra-sensory perception (the origin of which is utterly mysterious) is admitted, it may be expected to produce many other secondary effects that are surely not more surprising than the existence of the faculty itself.

For, whatever this power may ultimately prove to be, it certainly seems to have some attributes of human intelligence and is not merely a random physical process. It may well be that the subjects who possess this mysterious means of acquiring information have also subconscious personal predilections for certain types of effect, and can at times produce them by unconscious motivation. Thus, we know that one of Prof. Rhines's major subjects could at will orient his mind so as to produce below-chance scores instead of his usual high scores.

S. G. Soal

28 Thurleigh Road,
London, S.W.12.

[1] *J. Parapsychol.*, **6**, 52 (1942).
[2] Greenwood, J. A., *J. Parapsychol.*, **5**, 245 (1941).
[3] Rhine, J. B., *J. Parapsychol.*, **5**, 183 (1941).

Dr. Soal agrees that there is a periodicity in the 'guessers' scores which are related to the line numbers on the score sheet. He calls this effect 'salience' and I will also use this nomenclature. It must, however, be understood that by 'salience' we mean this periodicity in the scores without advancing any theory as to its cause.

Dr. Soal and I agree on the fact that Shackleton consistently produced scores which cannot be attributed to chance. Dr. Soal attributes these scores to telepathy. He regards salience effects as secondary characteristics of telepathy and to explain them he introduces subsidiary hypotheses which can be summarized as follows: (1) Certain guessers 'subconsciously' divide the sequence of twenty-five trials into five 'tasks' of five trials each. Other guessers think of the whole twenty-five trials as the 'task'. (2) At some point in the task, whichever type it be, either towards the end of it, or in the middle of it, or at the two ends of it and not in the middle, some guessers lose their telepathic abilities and their scores fall to the chance-level. (3) In the case of other guessers, they do not lose their telepathic abilities at these positions in the task, but they are "unconsciously motivated" to avoid securing hits and their scores fall below the chance-level.

I have shown that the results of the Soal–Goldney experiment could have been produced by means of a trick which involved memorizing a code. The particular salience effect produced by Shackleton would inevitably arise if such a trick was used, although its presence in the grouped data could be masked if the operators changed their code in a systematic manner.

It is not surprising that salience effects have been observed in other experiments on extra-sensory perception; for they may arise if there are factors which are not adequately controlled in the experimental conditions, or if a trick is being employed. It should further be noted that both errors due to poor experimental design, and confessed trickery, are not uncommon in psychical research, whereas precognition and telepathy are hypothetical processes.

In the case of the Shackleton experiments the issue is quite clear. The scores produced by Shackleton could be obtained by using a trick. Such a trick would, possibly, but not necessarily, reveal itself by causing a periodicity to arise in the scores. Such a periodicity is present in the results of the 'rapid-rate' experiments. It cannot be explained away by calling it 'salience', for this is merely another name for the observed periodicity. To explain salience effects in terms of telepathy, Dr. Soal has produced a number of subsidiary hypotheses which I regard as being as unlikely as is the existence of precognitive-telepathy itself.

C. E. M. Hansel

Department of Psychology,
University of Manchester.

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, March 28

Royal Geographical Society (at 1 Kensington Gore, London, S.W.7), at 5 p.m.—Miss A. Coleman and Mr. K. R. A. Maggs: "A New Land Use Survey".

Radar and Electronics Association (at the Royal Society of Arts, John Adam Street, Adelphi, London, W.C.2), at 7.30 p.m.—Mr. Peter D. Hall: "Computers—Some Design Problems of Large Scale Computers".*

Tuesday, March 29

Institution of Electrical Engineers, Education Discussion Circle (at Savoy Place, London, W.C.2) at 6 p.m.—Discussion on "The Place of Illumination in Electrical Engineering", opened by Mr. G. F. Freeman.

Institution of Mechanical Engineers, Education Group (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "The Need for Post-Graduate Refresher Courses for Engineers in Industry".

Society of Instrument Technology (at Manson House, 26 Portland Place, London, W.1), at 7 p.m.—Mr. G. G. Bloodworth: "Application of Transistors in Instrumentation".

Tuesday, March 29—Thursday, March 31

Institute of Metals (at Church House, Great Smith Street, Westminster, London, S.W.1)—Spring Meeting.

Tuesday, March 29

At 11 a.m.—Sir Ronald Prain, O.B.E.: "Mineral Resources and Metal Reserves" (Presidential Address).

At 6.30 p.m.—Prof. P. M. S. Blackett, F.R.S.: "The Magnetism of Rocks and Continental Drift" (May Lecture).

Wednesday, March 30

Institute of Metals, Metal Physics Committee (in the Hoare Memorial Hall, Church House, Great Smith Street, Westminster, London, S.W.1), at 2.30 p.m.—Meeting on "New Aspects of the Electron Theory of Metals".

Oil and Colour Chemists' Association, London Section (at the Royal Society of Tropical Medicine and Hygiene, Manson House, 26 Portland Place, London, W.1), at 7 p.m.—Dr. H. B. Footner: "Painting in the Petroleum Industry".

Wednesday, March 30—Thursday, March 31

Plastics Institute (at the University of London, London, W.C.1)—Conference on "Polymeric Progress".

Thursday, March 31

Institute of Metals (at Convocation Hall, Church House, Great Smith Street, London, S.W.1), at 10 a.m.—Discussion on "Vacancies, Ageing and Precipitation".

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Dr. N. F. Astbury: "Science in the Ceramic Industry".

Mineralogical Society (at the Geological Society of London, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Scientific Papers.

University of London Institute of Education (in the Great Hall, Goldsmiths' College, New Cross, London, S.E.14), at 5 p.m.—Sir Edward Boyle, Bt., M.P.: "Education—Tradition and Change".*

Institution of Electrical Engineers (at Savoy Place, London, W.C.2), at 5.30 p.m.—Prof. C. F. Powell, F.R.S.: "Cosmic Radiation" (Fifty-first Kelvin Lecture).

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Lecturer (male) **in Chemistry**—The Principal, Borough Road College, Isleworth, Middlesex (March 31).

Lecturer (Physical Chemist, with postgraduate research experience, and preferably a higher degree and experience in electronics) **in the Department of Electrical Engineering**—Prof. A. Tustin, Department of Electrical Engineering, Imperial College of Science and Technology, London, S.W.7 (March 31).

Lecturer (with a specialized knowledge in at least one of the following fields and prepared to undertake or supervise research: metallurgical analysis, refractories, nonferrous extraction, physical metallurgy) **in Metallurgy**—The Registrar, The Manchester College of Science and Technology, Manchester 1 (April 2).

Research Officer (graduate, with an honours degree in geography, and planning experience) **in the County Planning Department**—The Establishment Officer, Shire Hall, Bedford (April 2).

Biochemist (M.Sc. or Ph.D. in biochemistry or physiological chemistry, and at least three years experience in the procedures of biochemistry or chemical pathology) with the Limerick County Council, Ireland—The Secretary, Local Appointments Commission, 45 Upper O'Connell Street, Dublin (April 5).

Senior Technician (skilled cartographer) **in the Department of Geography**—The Registrar (GST), Queen Mary College (University of London), Mile End Road, London, E.1 (April 8).

Lecturer (medically or non-medically qualified) **in Biochemistry**; an **Assistant** (medically or non-medically qualified) **in Physiology**; and an **Assistant** (preferably applied mathematician) **in Mathematics**—Joint Clerk to the University Court, Queen's College (University of St. Andrews), Dundee (April 9).

Lecturer (with qualifications and a special interest in the teaching of chemistry) **in Education**—The Registrar, The University, Sheffield (April 9).

Assistant Lecturer or **Lecturer** (with a special interest in the philosophy of science) **in Philosophy**—The Registrar, The University, Hull (April 12).

Departmental Assistant in Animal Physiology at the School of Agriculture, Sutton Bonington, near Loughborough, for demonstration and laboratory work in animal physiology, with opportunities for research—The Registrar, The University, Nottingham (April 12).

Lecturer (with special qualifications in engineering geology, including hydrology and soil science) **in the Department of Geology**, University of the Witwatersrand, Johannesburg, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (South Africa and London, April 15).

Assistant Professor of Physical Chemistry in the Faculty of Arts and Science, Memorial University of Newfoundland, Canada—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Canada and London, April 15).

University Lecturer in Statistics—The Secretary of the Appointments Committee of the Faculty of Mathematics, the Arts School, Bene't Street, Cambridge (April 18).

Chair of Soil Science in the Faculty of Agriculture, University of Khartoum—The Registrar, University of Khartoum, c/o Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (April 20).

Assistant Lecturers or **Lecturers** (2) (with a good honours degree in geology) **in the Department of Geology**—The Registrar, University College of North Staffordshire, Keele, Staffs (April 23).

Lecturer in the Department of Geography, University of the Witwatersrand, Johannesburg, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (South Africa and London, April 25).

Lecturer or **Assistant Lecturer** (man or woman graduate with a special interest in petrology) **in Geology**—The Secretary, Bedford College (University of London), Regent's Park, London, N.W.1 (April 25).

Assistant Lecturer in Physiology at the University of Hong Kong—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Hong Kong and London, April 29).

Lecturer in Chemical Engineering—The Registrar, University College, Singleton Park, Swansea (April 30).

Post-Doctoral Research Fellow in the Department of Organic Chemistry, to work in collaboration with Dr. A. R. Battersby on the chemistry of natural products, particularly in the alkaloid field—The Registrar, The University, Bristol (April 30).

Scientific Officers/Senior Scientific Officers (with a first- or second-class honours degree, previous research experience in some experimental branch of physics, chemistry or engineering, and at least three years postgraduate experience for Senior Scientific Officer) **in the Basic Physics Division**, National Physical Laboratory, Teddington, Middlesex, to do fundamental research on physical and chemical properties of solids at very high pressures—The Ministry of Labour, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.119.OA (April 30).

Senior Lecturer in Physical Chemistry at the University of Natal, Pietermaritzburg, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (South Africa and London, April 30).

Demonstrator in Physical Chemistry—Head of the Physical Chemistry Laboratory, The University, South Parks Road, Oxford (May 15).

Chief of the Division of Land Research and Regional Survey, Commonwealth Scientific and Industrial Research Organization, Canberra, A.C.T., Australia—Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting Appointment No. 570/84 (May 21).

Post-Doctoral Fellows (2) **in the Chemistry Department**, for work on (*a*) electrode processes and (*b*) thermodynamics of polymer solutions—Prof. B. E. Conway, Department of Chemistry, University of Ottawa, Ottawa, Canada (May 21).

Assistant Editor (man or woman graduate with some knowledge of chemistry, and preferably sub-editing experience with scientific publishers) for the less academic aspects of scientific publications—The General Secretary, The Chemical Society, Burlington House, Piccadilly, London, W.1.

Assistant Experimental Officer (with at least G.C.E., Scottish Leaving Certificate, Higher National Certificate, or equivalent, and some experience of histological techniques), to undertake histological work and to assist in the Pathology Department—The Secretary, Rowett Research Institute, Bucksburn, Aberdeen.

Assistant, Grade B (with a good honours degree, and preferably industrial or research experience), for mathematics—The Clerk to the Governors, South-East Essex Technical College, Longbridge Road, Dagenham, Essex.

Assistant Professor to teach Metallurgical Thermodynamics and Kinetics—Head, Department of Metallurgy, Montana School of Mines, Butte, Montana.

Demonstrator in Biology within the Department of Botany and Zoology—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1, or the Registrar, University of Adelaide, Adelaide, Australia.

Experimental Physicists (with at least a good second-class honours degree and preferably postgraduate experience in some aspect of nuclear physics), to (*a*) collaborate with physicists designing a 7-GeV. proton synchrotron, and take responsibility for aspects of selection, analysis and transport of high energy beams and eventually

AC 43.1

to participate in high energy nuclear research; and (*b*) to work with nuclear physicists using a 50-MeV. linear accelerator and collaborate with university physicists using this machine—The Secretary, Rutherford High Energy Laboratory, Harwell, Didcot, Berkshire, quoting Ref. 1637/34.

MASTER (with high academic qualifications) TO TEACH MATHEMATICS to open scholarship standard; and a MASTER TO TEACH PHYSICS AND/OR CHEMISTRY to A level—The Headmaster, Blundell's School, Tiverton, Devon.

PHYSICIST (with a degree or equivalent in general science including physics, or in chemistry with physics subsidiary, experience in handling radioactive materials and health physics, and preferably a knowledge of electronics and/or general explosive practice) at the Ministry of Aviation H.Q., London, to be responsible for developing effective production methods for radioactive and allied materials and supervision of safety methods allied to health physics at the factory—The Ministry of Labour, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting Ref. A.118/O.A.

PRINCIPAL GRADE PHYSICIST (with experience either in hospital physics or in some relevant field, such as biophysics, electronics or nuclear physics), to initiate work on physics applied to the various fields of medicine (other than radiotherapy)—The House Governor, The Queen Elizabeth Hospital, Edgbaston, Birmingham 15.

SENIOR LABORATORY TECHNICIAN, to be responsible for new physics teaching laboratories and lecture demonstrations up to degree standard—The Secretary, King's College, Strand, London, W.C.2, quoting Ref. 3066.

SENIOR TECHNICIAN II (with some organizing ability, and preferably previous experience in medical or biological research) IN THE CANCER RESEARCH LABORATORY, for work in connexion with the cytology and cytochemistry of human tumours—The Administrative Officer, Mount Vernon Hospital, Northwood, Middx.

SOIL CHEMIST (with an honours degree in chemistry, or in natural science including chemistry, and at least two years postgraduate training or experience as a soil chemist) at the West African Institute for Oil Palm Research, Nigeria, for the study and analysis of soil types with a view to improving soil conditions—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.197/199/016/T.

REPORTS and other PUBLICATIONS

(not included in the monthly Books Supplement)

Great Britain and Ireland

British Steel Castings Research Association. British and Foreign Specifications for Steel Castings, Part 1—Summaries, Comparisons and other relevant Information. Pp. xiv+48. (Sheffield: British Steel Castings Research Association, 1959.) 40*s.*; 7.50 dollars. [121

Society for Freedom in Science. Occasional Pamphlet No. 19 (December, 1959): Opposition Aroused in China by Marxist Planning of Scientific Research. Pp. ii+16. (Oxford: Dr. John R. Baker, Dept. of Zoology, University Museum, 1959.) [121

Ministry of Agriculture, Fisheries and Food. Fishery Investigations, Series II, Vol. XXII, No. 8: The Spawning of the Plaice (*Pleuronectes platessa*) in the Irish Sea. By A. C. Simpson. Pp. ii+30. (London: H.M. Stationery Office, 1959.) 9*s.* net. [121

University Scholarships for Student Apprentices in Electrical, Electronic and Mechanical Engineering. Pp. vii+23 (7 plates). (London: H.M. Postmaster General, 1960.) [121

Institute of Physics. The Teaching of Mathematics to Physicists. Revised Report. Pp. 25. (London: Institute of Physics, 1959.) 2*s.* 6*d.* [121

Ministry of Labour. Factories Acts, 1937 and 1948. Factories-(Ionising Radiations)-Special Regulations—Second Preliminary Draft of Regulations. Pp. 20. (London: H.M. Stationery Office, 1960.) 1*s.* 3*d.* net. [121

Society for the Bibliography of Natural History. Essai sur la Geographie des Plantes (1807). Par Alexander von Humboldt. (Sherborn Fund Facsimile, No. 1). Pp. 38+1 plate. (London: Society for the Bibliography of Natural History, c/o British Museum (Natural History), 1959.) 10*s.* [121

At the Farmer's Service: a Handy Reference to Various Services available to Farmers in England and Wales. Pp. 79. (London: Ministry of Agriculture, Fisheries and Food, 1959.) [121

University of Cambridge School of Agriculture Memoirs. No. 31: A summary of the papers published by the members of the Staff of the School of Agriculture and its Associated Research Organisations during the period Oct. 1st, 1958—Sept. 30th, 1959. Review Series No. 14: Statistics—a Retrospect. Pp. 28. (Cambridge: University of Cambridge School of Agriculture, 1959.) [121

The Registrar General's Statistical Review of England and Wales for the year 1958. Part 2: Tables, Population. Pp. xi+181. (London: H.M. Stationery Office, 1960.) 11*s.* 6*d.* net. [261

Ministry of Housing and Local Government: Central Advisory Water Committee. Final Report of the Trade Effluents Sub-Committee of the Central Advisory Water Committee. Pp. iv+52. (London: H.M. Stationery Office, 1960.) 3*s.* 6*d.* net. [261

Ciba (A.R.L.), Ltd. Technical Notes, No. 205 (January 1960): The Durability of 'Aerolite' 300. Pp. 20. (Duxford: Ciba (A.R.L.), Ltd., 1960.) [261

Southern Regional Council for Further Education. Twelfth Annual Report, October 1959. Pp. 40. (Reading: Southern Regional Council for Further Education, 1959.) [261

Memoirs of the Royal Astronomical Society. Vol. 68, Part 2: A Survey of Radio Sources at a Frequency of 159 Mc/s. By D. O. Edge, J. R. Shakeshaft, W. B. McAdam, J. E. Baldwin and S. Archer. The Positions, Flux Densities and Angular Diameters of 64 Radio Sources Observed at a Frequency of 178 Mc/s. By B. Elsmore, M. Ryle and Patricia R. R. Leslie. Pp. 37–67. (London: Royal Astronomical Society, 1959.) 12*s.*; 1.90 dollars. [261

Royal Institute of Chemistry. Lectures, Monographs and Reports, 1959. No. 3: Some Chemical Aspects of Plant Disease Control. By Dr. R. L. Wain. Pp. ii+21. 4*s.* 6*d.* No. 4: Chemical Mechanisms in the Induction of Cancer. By Dr. Alexander Haddow. Pp. ii+21. 4*s.* 6*d.* net. No. 5: Modern Explosives. By the late Dr. Wilfrid Taylor. Pp. 63. 6*s.* net. (London: Royal Institute of Chemistry, 1959.) [261

G.B. Film Library. Educational Films, Issue No. 26. Pp. 120. Filmstrips, 1959–1960. Pp. 72. (Perivale, Middx.: G.B. Film Library, 1959.) [261

Other Countries

University of California Publications in Geological Sciences. Vol. 36, No. 2: Pliocene and Lower Pleistocene of the Western Part of the San Francisco Peninsula. By William Glen. Pp. 147–198+plates 15–17. (Berkeley and Los Angeles: University of California Press: London: Cambridge University Press, 1959.) 1 dollar. [61

Annual Report of the Board of Regents of the Smithsonian Institution showing the Operations, Expenditures, and Condition of the Institution for the year ended June 30, 1958. (Publication No. 4354.) Pp. x+559+107 plates. (Washington, D.C.: Government Printing Office, 1959.) 3.75 dollars. [61

National Institute of Genetics, Japan. Annual Report, No. 9, 1958. Pp. v+144. (Misima, Sizouka-ken: National Institute of Genetics, 1959.) [61

The Plant Galls of Norway: a Preliminary Catalogue based on the collection of the Zoological Museum, University of Bergen. By Donald Leatherdale. (Universitetet i Bergen Årbok 1959—Naturvitenskapelig rekke Nr. 8.) Pp. 56. (Bergen: A. S. John Griegs Boktrykkeri, 1959.)

Centro Brasileiro de Pesquisas Fisicas. Notas de Fisica. Vol. 5, No. 10: Algebras of Finite Differential Order and the Operational Calculus. By Leopoldo Nachbin. Pp. 105–142. Vol. 5, No. 11: The Form Factors in $K\mu$, and Ke Decay. By S. W. MacDowell. Pp. 143–155. Vol. 5, No. 12: Gamma Rays in the Decay of 141[illegible]a. By E. W. Cybulska and L. Marquez. Pp. 157–163. Vol. 5, No. 13: Decay of $\Lambda_0 \rightarrow n + \gamma$ Through Non Local Fermi Interactions Due to Vector Mesons. By J. L. Acioli. Pp. 165–177. (Rio de Janeiro: Centro Brasileiro de Pesquisas Fisicas, 1959.) [61

India: Council of Scientific and Industrial Research. National Metallurgical Laboratory Annual Report, 1958–59. Pp. iii+49. (Jamshedpur, Bihar: National Metallurgical Laboratory, 1959.) [121

Proceedings of the American Philosophical Society. Vol. 103, No. 6 (December 15, 1959): Studies of Historical Documents in the Library of the American Philosophical Society. Pp. ii+727–821. (Philadelphia: American Philosophical Society, 1959.) 1 dollar. [121

Journal of Nuclear Energy, Part C: Plasma Physics—Accelerators—Thermonuclear Research, Vol. 1, Nos. 1/2 (October, 1959). Pp. 104. Subscription rates (a) per volume: 20 dollars, 140*s.* including postage. (b) per annum for subscribers who notify the Publisher direct certifying that the journal is for their private use, 30 dollars, 210*s.* including postage. Back numbers 28 dollars, 200*s.* per volume. (New York and London: Pergamon Press, 1959.) [121

Companhia de Diamantes de Angola (DIAMANG). Servicos Culturais. Dundo—Lunda—Angola. Museu do Dundo. Subsidios para o Estudo da Biologia na Lunda. Publicacoes Culturais No. 42: Contribution à l'Étude de la Flore de la Lunda d'Après les Récoltes de Gossweiler (1946–1948). Par A. Cavaco. Pp. 230. (Lisboa: Companhia de Diamantes de Angola, 1959.) [261

University of California Publications in Botany. Vol. 31, No. 1: Cytogenetic and Evolutionary Studies in the Genus *Dactylis*. 1: Morphology, Distribution, and Interrelationships of the Diploid Subspecies. By G. Ledyard Stebbins and D. Zohary. Pp. 1–40+plates 1–3. (Berkeley and Los Angeles: University of California Press; London: Cambridge University Press, 1959.) 75 cents. [261

Metropolitan Life Insurance Company. Statistical Bulletin, Vol. 40 (November–December 1959): New Weight Standards for Men and Women. Fathers are Younger. How Fatal Accidents Occur in the Home. Geographic Variations in Mortality by Cause. Pp. 12. (New York: Metropolitan Life Insurance Company, 1959.) [261

Mitteilungen aus der Biologischen Bundesanstalt für Land- und Forstwirtschaft, Berlin-Dahlem. Heft 97 (November 1959): 32 Deutsche Pflanzenschutz-Tagung der Biologischen Bundesanstalt für Land- und Forstwirtschaft in Hannover, 6-10 Oktober 1958. Pp. xxii+239. (Berlin-Dahlem: Biologische Bundesanstalt für Land- und Forstwirtschaft, 1959.) 12.80 D.M. [261

Bernice P. Bishop Museum Special Publication No. 47: Fishhooks. By Kenneth P. Emory, William J. Bonk and Y. H. Sinoto. (Hawaiian Archaeology). Pp. xiii+45+6 plates. (Honolulu: Bernice P. Bishop Museum, 1959.) [261

Commonwealth of Australia. Department of Supply—Australian Defence Scientific Service. Annual Report of the Defence Standards Laboratories for the year ended 30th June, 1959. Pp. iv+75. (Maribyrnong, Victoria: Defence Standards Laboratories, 1959.) [261

Queensland. Fourteenth Annual Report of the Council of the Queensland Institute of Medical Research, year ended 30th June, 1959. Pp. 24. (Brisbane: Queensland Institute of Medical Research, 1959.) [261
